ABSTRACT

The area from Great Slave Lake to the Mackenzie delta and east to the Coronation Gulf area of Nunavut is the wintering range for several barren-ground caribou herds including the Cape Bathurst, Bluenose-West, Bluenose-East and Bathurst herds. Between February and April 2004 we surveyed this area in order to map the distribution of wintering caribou, as some communities had reported the absence of caribou from some of their typical wintering areas. We used fixed winged aircraft flown along predetermined transect lines to map the caribou distribution in survey areas. We found that caribou were widely distributed across the western NWT in late winter 2004 and that the highest concentration of caribou was found southwest of Great Bear Lake. Lower numbers of caribou were on the arctic coast northeast of Tuktoyaktuk and a band of caribou was spotted extending southeast from Inuvik to northeast of Colville Lake. There were also caribou along the east side of Great Bear Lake to east of the Coppermine River. The Bluenose-West herd normally winters from the southern Tuktoyaktuk Peninsula and Husky Lakes area to Paulatuk and south to Great Bear Lake. However, in winter 2003-2004, most caribou appeared to winter in the area of Great Bear Lake, possibly in response to freezing rain along the coast and deeper snow than usual in the Inuvik Region. As expected, there was also some overlap found between the herds in the use of winter ranges.

INTRODUCTION

In late winter 2004 hunters from Colville Lake, Fort Good Hope, Norman Wells, and Paulatuk reported an absence of barren-ground caribou *Rangifer tarandus groenlandicus* near their communities. In response to community concerns we planned aerial surveys based out of Inuvik and Norman Wells to map the distribution of caribou from the Bluenose-East, the Bluenose-West and the Cape Bathurst herds.

Community knowledge provides considerable information on caribou winter distribution. However, this information is not readily available until it is compiled into a more accessible source such as maps. In addition to the unavailability of caribou distribution information, the Great Bear Lake area was last covered during previous winter aerial surveys between 1949 and 1960, and 1966 and 1981 (Carruthers and Jakimchuk, 1981).

Herd size and the condition of wintering range affect annual caribou winter ranges. A map was needed to understand how the caribou had shifted their distribution. As a basis for comparison of areas used in recent winters, we had information on caribou distribution based on satellite collars (Figure 1) (Nagy *et al.*, in prep.; Gunn *et al.*, 2001). The ability to identify the movements of known individual caribou allowed us to describe the overlap between herds in their use of winter ranges (Nagy *et al.*, in prep.; Gunn and D'Hont, 2003).

1

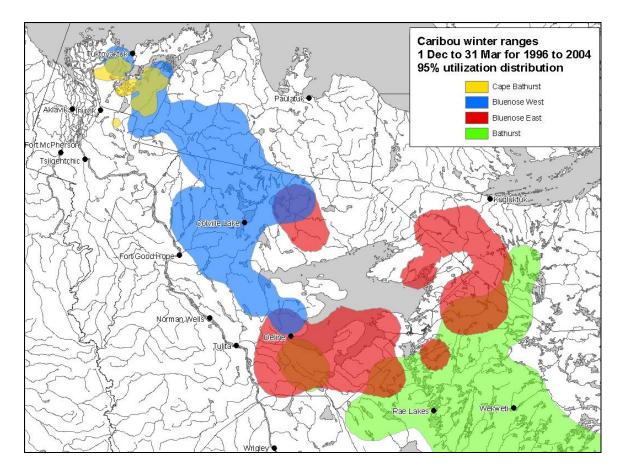

Figure 1. Overlap in winter ranges for the barren-ground caribou herds, NWT, based on satellite-telemetry of cows, 1996–2004.

The number of collared cows was low. In March 2004 we had seven cows fitted with satellite-collars from the Bathurst herd and three cows fitted from the Bluenose-East herd. One satellite-collared cow from the Bluenose-East herd was wintering east of the Coppermine River, and the other two collared cows were south of Great Bear Lake and west of Gameti. Five of the Bathurst collared cows were east of Gameti and two were southeast of Lutsel K'e. For the Bluenose-West and Cape Bathurst herds, we had two and four satellite collars, respectively.

We planned late winter aerial surveys to map the caribou distribution to include and extend beyond the locations of the satellite-collared cows. We maximized the extent of the geographic area covered by increasing the distances between the transect lines (thus reducing coverage). The survey was planned to map relative distribution rather than estimate caribou numbers.

This report describes two initial late winter (March) aerial surveys on the winter ranges of the Cape Bathurst, Bluenose-West, and Bluenose-East herds. The first survey took place southwest of Great Bear Lake and revealed relatively large numbers of caribou close to Deline. The second survey was an attempt at radio telemetry in search of 2001 vhf collars. This survey would identify if the caribou southwest of Deline were Bluenose-East or Bluenose-West herds. Results of the one-day radio-tracking flight are included in this report. We also added a third aerial survey flown in April to extend the area northeast of Great Bear Lake, where Inuit from Kugluktuk were hunting caribou, and where there was a Bluenose-East satellite-collared cow.

METHODS

Using Inuvik as a base in March 2004, we (JN) flew in a Cessna 185 at approximately 150 m above ground, with an air speed of approximately 160 km/h. We counted caribou within a 0.5-km strip on either side of the aircraft along transects spaced at 20 km. We left the transect to count any animals seen off-transect. We stored all wildlife sightings and tracks as waypoints and the aircraft's track was recorded by the Global Positioning System in the survey aircraft. Prior to flying the survey, information from hunters and pilots on the distribution of caribou was used to guide the application of survey coverage by avoiding areas known to have no caribou. We (RP) flew out of Norman Wells in March 2004 and used a Helio-Courier aircraft flown at 150 m above ground (agl) at an air speed of approximately 160 km/h. The radio-tracking flight was in a Cessna 206 flown at 3,000 m agl. Most of the known winter range of barren-ground caribou in the Sahtu Settlement Area (SSA) was surveyed. As with the Inuvik surveys, local information aided decisions on which areas to fly. Line transect spacing was 20 km below tree line and 30 km northeast of Great Bear Lake.

In areas with few lakes, areas below the tree line and during low light conditions concentrations of localized caribou were probably missed. This was particularly the case between Aubrey Lake, Tedji Lake and Simpson Lake. Above tree line survey coverage at 30 km spacing was good. All caribou observed at any distance were included.

The April 2004 survey was in a Cessna 337 based at Norman Wells and Kugluktuk. We (RP) flew at approximately 150 m to 600 m agl at approximately 160 km/h. The selection of survey area was based on local knowledge of caribou distribution from hunters, and also to cover the area not covered by the March surveys. We flew each transect until about 10 km beyond the last caribou or caribou track sightings.

RESULTS

On the flights east and southeast of Inuvik (Figures 2 and 3), between 24 and 28 March 2004, we counted a total of 634 caribou on transect and an additional 387 off transect. We also counted 16 moose *Alces alces* and 50 muskoxen *Ovibos moschatus* (Figure 4). The distance flown was 5600 km. Weather conditions at the time of the survey were clear and sunny with excellent visibility over 100% snow cover. Temperatures were in the low to mid -30 °Cs during most of the survey. The inadequate heater in the aircraft meant that we had to frequently scrape ice off the window, resulting in reduced visibility.

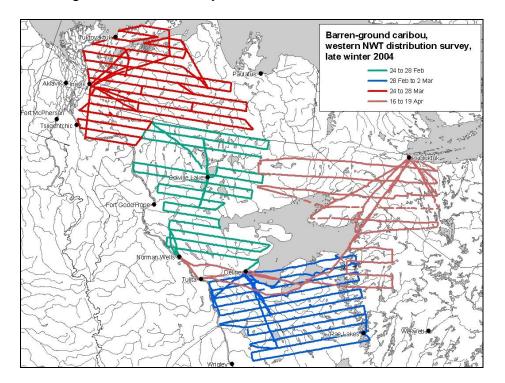

Figure 2. Flight lines flown in February, March and April 2004, NWT.

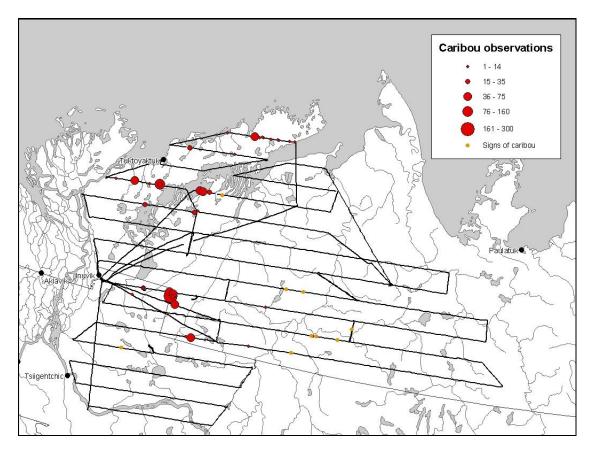

Figure 3. Caribou and signs observed on and off transect, 24 to 28 March, 2004 east of Inuvik, NWT.

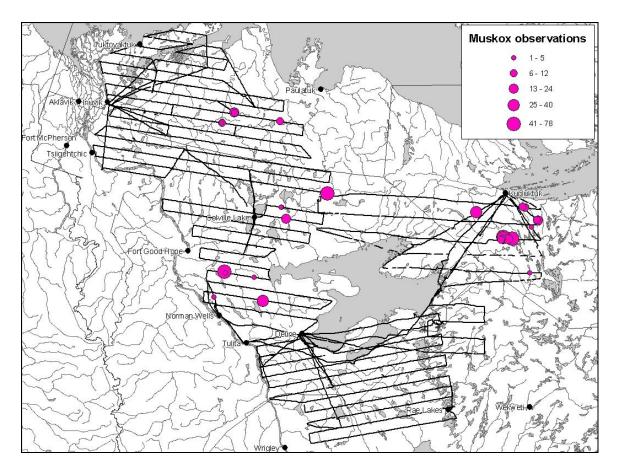

Figure 4. Muskoxen observed along transects flown February to April, 2004.

In Sahtu Settlement Area, the area northwest of Great Bear Lake was flown 24 to 28 February (Figures 2 and 5). We counted 1,694 barren-ground caribou on the transects. We also counted 17 boreal woodland caribou *Rangifer tarandus caribou* (Figure 6), 149 moose, 177 muskoxen (Figure 4), 15 wolves *Canis lupus*, and 2 foxes. The distance flown was 4,600 km. Visibility was excellent, with clear weather conditions and temperatures in the -30 °Cs. Some flat light conditions occurred during occasional periods of light snow on 24 and 25 February. The gap in flight lines north of Colville Lake were the result of a GPS track recording problem, though the transects were flown and observations recorded (Figure 2).

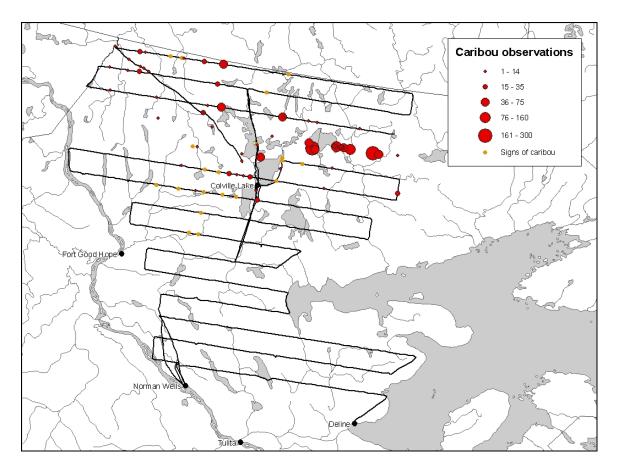

Figure 5. Caribou and signs observed along transect 24 to 28 February, 2004 northwest of Great Bear Lake, NWT.

On flights southwest of Great Bear Lake on 28 February to 2 March (Figures 2 and 7) we counted a total of 9,895 barren-ground caribou. Other species observed were 24 boreal woodland caribou (Figure 6), 78 moose and 4 wolves. The distance flown was 4,700 km. Weather was -30 °C with clear conditions, giving excellent visibility.

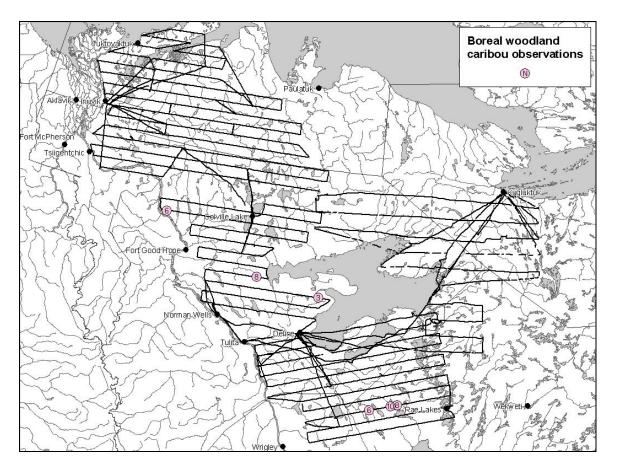

Figure 6. Boreal woodland caribou observed along transects flown February to April, 2004.

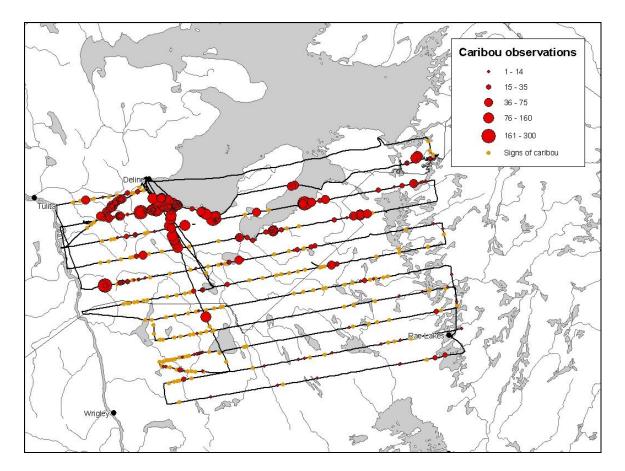

Figure 7. Caribou and signs observed along transect 28 February to 2 March, 2004 southwest of Great Bear Lake, NWT.

During the radio-tracking flight on 1 April 2004 (Figure 8), we (AV) heard an active Bluenose-West collar (ID # 347) on the south shore of Great Bear Lake (65 06 N; 121 58 W – 150.021 MHz) and a second Bluenose-West collar (ID # 353) in mortality mode near Dismal Lake, northeast Great Bear Lake (67 17 N; 117 39 W - 150.222 MHz). Conditions for this flight were generally good, except for the south side of Great Bear Lake. We were forced to fly further off over the lake by the Manitou Island area due to cloud and snow.

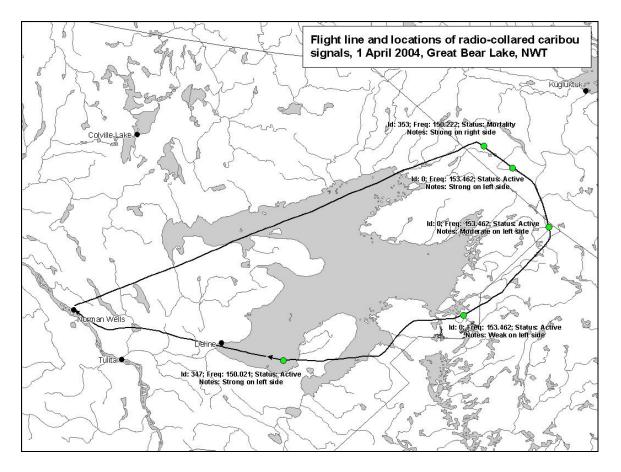

Figure 8. Flight line and locations of radio-collared caribou signals, 1 April 2004, Great Bear Lake, NWT.

We completed the aerial survey based out of Norman Wells and Kugluktuk between 16 and 19 April 2004 (Figures 2 and 9), and counted 1593 barren-ground caribou. We saw few caribou above the treeline. Most caribou were migrating along the east shore of Great Bear Lake. Another migration corridor was found north of Great Bear Lake from Anderson River (Manoir Lake vicinity) towards Bluenose Lake. We radio-tracked during the survey and located caribou ID # 347 again, but east of Hornby Bay this time (66'28" 46.0 N, 116 '22" 20.1 W). We counted 306 muskoxen (11 calves included) in 13 herds (Figure 4). Other observations included 10 moose and 4 wolves.

The distance flown was 5,550 km. The weather was clear with good visibility, and temperatures remained between -10 and -20 °C.

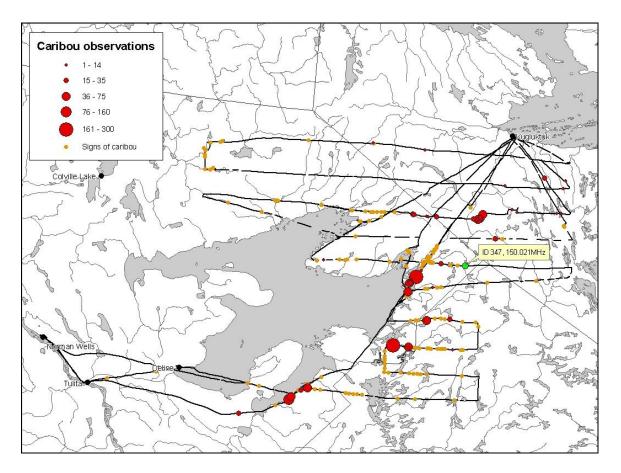

Figure 9. Barren-ground caribou and their signs observed along transect, 16–19 April 2004, Great Bear Lake, NWT to Kugluktuk, Nunavut.

Caribou Numbers

East of Inuvik, the survey was flown at 5% coverage. Caribou were counted within 0.5 km strip on either side of the aircraft, with transects spaced at 20-km intervals. The plane was flown at approximately 400–500 feet above ground level. We counted a total of 634 caribou on transect and an additional 387 off transect. For caribou seen on transect, our survey would account for a little over 12,000 animals. At such low coverage, this estimate has low reliability.

For the Sahtu-Nunavut survey, flying along line transects provided extensive coverage and a snapshot of caribou late winter distribution. Observers counted individual animals and estimated caribou group size of all caribou observed at any distance from the aircraft.

DISCUSSION

Small-scattered groups of barren-ground caribou were widely distributed across the Central NWT in late winter 2004. The highest concentration of caribou was located southwest of Great Bear Lake (Figure 10). Lower numbers of caribou used winter ranges on the arctic coast northeast of Tuktoyaktuk, with a band of caribou extending southeast from Inuvik to northeast of Colville Lake. The caribou distribution also extended along the east side of Great Bear Lake to east of the Coppermine River.

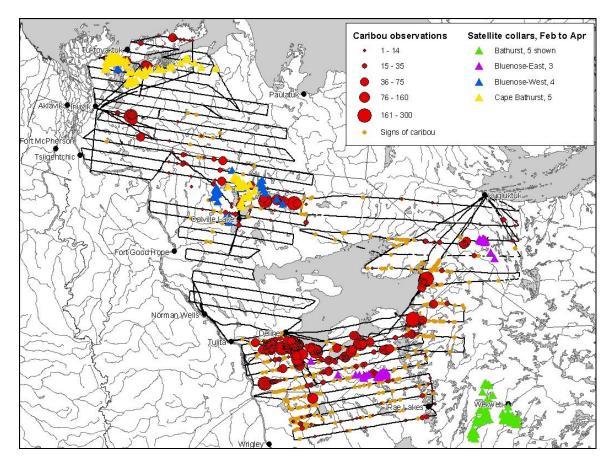

Figure 10. Caribou observations, flight lines and locations of satellite-collared caribou February, March and April 2004.

Hunters reported that there were no caribou in the area south of Paulatuk.

Hunters had traveled as far south as Simpson Lake in search of caribou. We

also did not fly the upper part of the Cape Bathurst Peninsula as we had reports from hunters and pilots traveling in the area that there were no caribou there.

In the Sahtu Settlement Area, there was no reports or local knowledge of barren-ground caribou west of the Mackenzie River outside of the known barrenground caribou range. East of the Mackenzie River, south of Bear River and Great Bear Lake, and north of Wrigley to Rae, there was evidence of intense caribou use. The southwestern extent of the distribution to the Mackenzie River and Wrigley was not determined as the transects stopped short. Possibly, caribou were not easily accessible to hunters at Wrigley as they carried out a community caribou hunt near Deline. In Fort Good Hope hunters were concerned that few caribou were wintering in areas near their community, and blamed oil and gas exploration activities. Local displacement of caribou from access routes may be due to noise and activity from traffic along winter roads. Larger numbers of caribou were usually present in the exploration areas near Fort Good Hope and Colville Lake before the Colville Lake winter road was built.

Colville Lake elders were concerned about disturbance from noise and activity from oil and gas exploration, and winter road development, upon caribou distribution. Fewer caribou were seen in 2003 compared to the past five years during the Colville Lake annual community hunt, taking place the first week of September at Horton Lake. This area is a fall migration corridor. Caribou tracks noted by Colville Lake people from helicopter flights in April indicated that caribou were very localized for a long time this winter. Deep snow may have hindered caribou movements in some locations. Norman Wells residents report no caribou were found crossing snowmobile trails between Fort Good Hope and Norman Wells, and Norman Wells to Smith Arm of Great Bear Lake. Caribou were not found migrating around the west end of Great Bear Lake before freeze up. People from Tulita reported that caribou were plentiful along the winter road from Bennett Field to Deline from December to April. Deline reported plentiful caribou south of Great Bear Lake close to the community from December to April. Concerns were expressed about people from other communities hunting on selected Sahtu lands, and that some hunters were disrespectful to caribou by leaving gut piles on or adjacent to the winter road.

Kugluktuk hunters observed an abundance of caribou in the Dismal Lakes to Caribou Point, Great Bear Lake area when there was little snow cover during October 2003 (pers. comm. M. Dumond). This was followed by a period of mild temperatures, then the absence of large numbers of caribou throughout the winter. Snow hardness and crust layer may have affected caribou range use in this area.

We have previously described the distribution of the Bathurst herd during unsystematic flights to locate groups for estimating calf survival (Gunn *et al.* 2005). The distribution of those flights (Figure 11) was based on locations of the satellite-collared caribou, hunters' reports and locations of wolves fitted with vhf collars. The herd wintered in an area extending from northwest to southeast of Great Slave Lake.

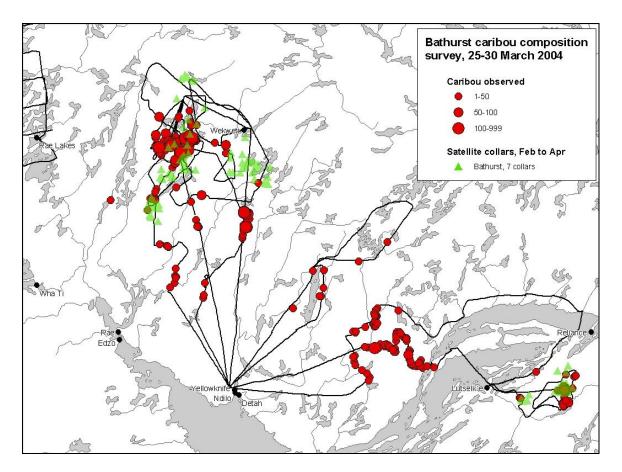

Figure 11. Caribou observations, flight lines and locations of satellite-collared caribou on the Bathurst herd's range, March 2004, NWT

Caribou distribution relative to satellite collars

The distribution of caribou in the western NWT in winter 2003/04 is consistent with two characteristics of their winter range use. The first characteristic involves caribou winter ranges varying between years. As barrencaribou winter distribution varies annually, the availability of caribou to communities using them is affected. The second characteristic of caribou wintering ranges is some overlap of winter ranges between neighboring herds.

Annual variation in the winter range

Annual variation in caribou winter range is well known, though it is only recently measurable through the use of satellite telemetry. Analyses using telemetry and weather data reveal how annual variation in the winter range partly reflects snowfall early in winter (McNeill *et al.* in prep.). Freezing rains followed by deep snow along the Arctic coast from Cape Bathurst to Paulatuk during fall 2003 may have caused caribou of the Bluenose-West and Cape Bathurst herds to winter south of their normal wintering ranges. The Inuvik area experienced the deepest late winter snow conditions observed by people in the area (Nagy *et al.* 2004).

An indication of the scale of variation in the winter ranges can be estimated from telemetry data. For example, Gunn *et al.* (2001) estimated that satellite-collared cows in the Bathurst herd used winter ranges that were variable in overlap between successive winter ranges. On average the overlap was $31 \pm 17.7\%$ SE and varied from no overlap (1996/97 and 1997/98) to 75% (1998/99 and 1999/00).

Likewise, the winter distribution of the Cape Bathurst, Bluenose-West and Bluenose-East herds varies between years. In the 1960s to 1980s, the areas used north of Great Bear Lake varied between surveys, with some areas used more frequently (Carruthers and Jakimchuk, 1981). The area north of the Hare Indian River and west of the Horton River, and the Caribou Point areas, were two frequently used forested areas. On the tundra the Rae-Richardson River area and Dismal Lakes were two frequently used areas. More recently, based on satellite collared caribou cows, we have determined that the Cape Bathurst herd typically winters in the area of Tuktoyaktuk Peninsula and Husky Lakes. However, in winter 2003-2004, two satellite collared Cape Bathurst cows wintered near Colville Lake (Nagy *et al.*, in prep).

Caribou of the Bluenose-West herd normally winter in the area from the southern Tuktoyaktuk Peninsula and Husky Lakes area to Paulatuk and south to Great Bear Lake. However, in winter 2003-2004, most caribou appeared to winter in the area of Great Bear Lake (Nagy *et al.*, in prep).

Winter Range Overlap

The second characteristic of barren-ground caribou winter range use is that overlap between herds is common. Heard (1984) originally described overlapping winter range for the Beverly and Qamanirjuaq herds based on hunters returning ear-tags. Overlap between neighboring herds of barren-ground caribou in the NWT is now recorded using satellite-collars on cows (Gunn, in Prep.; Nagy *et al.,* in Prep.; Gunn *et al.,* 2001; Gunn and D'Hont, 2003).

The Bluenose-East herd, over the last several years, typically winters in areas south, east and northeast of Great Bear Lake. The observed highest concentration of caribou in this area in winter 2003-2004 suggests that this herd was mostly on its normal wintering area, overlapping to some extent with caribou from other herds. The collared Bluenose-West cow ID # 347 observed in the Manitou Island area in early April indicates overlap between Bluenose-West and Bluenose-East. The Bluenose-East and the Bathurst herd ranges also overlap in some winters (Gunn, in prep.). Based on satellite collar data, ranges did not overlap in the 2003-04 winter. Microsatellite DNA analysis has been suggested as a potential tool for determining which herd is being harvested in an area where herd distribution overlap occurs.

The satellite-collared cows allow us both to map an annual winter range for those cows, and also to confirm any overlapping winter ranges between neighboring herds. However, the distribution of the satellite-collared cows is unlikely to completely represent any one herd's total winter distribution. Firstly, only cows are fitted with satellite-collars, so the distribution of bulls is not adequately represented. It is common for bulls to winter further south than cows (Kelsall, 1968). Secondly, the number of cows fitted with satellite collars is relatively low, at between 10-20 cows.

We currently lack data to test how the distribution of satellite collared cows relates to overall winter distribution. An opportunity to compare the winter range determined from collared cows versus systematic aerial surveys will be in March 2006, when some 160 caribou from the Bluenose-East, Bluenose-West and Cape Bathurst herds will have been collared (vhf and uhf collars) in March 2005. These cows will join the 10 - 20 Bathurst herd cows already satellite collared. Systematic aerial survey and radio-tracking will allow a comparison of the two measures of winter distribution.

Satellite collars are now used to determine seasonal caribou availability to hunters (Prichard *et al.,* 2003) by comparing subsistence-use areas to the distribution of satellite-collared cows. McNeill *et al.* (in prep.) have taken this

approach a step further by including how categories of environmental variation affect distribution in their studies.

The question of the number of satellite-collared individuals required to measure caribou distribution relative to community hunting areas, for example, is currently unknown. Otto *et al.* (2003) modeled statistical power relative to sample size and suggested that 15 - 52 collared individuals were necessary to detect 50% probability of representative distribution in a herd of 350 – 525,000 caribou. Trimper and Chubbs (2003) and Boulanger *et al.* (2004) took a more empirical approach by measuring caribou densities relative to locations of satellite-collared caribou. The collared caribou were relatively representative of the caribou densities, although seasonal variation was high (Boulanger *et al.,* in prep.; Trimper and Chubbs, 2003).

ACKNOWLEDGEMENTS

We thank observers Glen Guthrie (Sahtu Renewable Renewable Resources Board), Mathieu Dumond (Department of the Environment, Kugluktuk, Nunavut), Trudy Kochon (Colville Lake RRC) and Johnny Vital (Deline RRC) who were on the Sahtu–Kugluktuk area surveys. We flew in North Wright Air Service's Cessna 337 with pilot Trevor Narraway and in North Wright Air Service's Helio-Courier with Perry Linton. Thanks to Tommy Chicksi (Inuvik HTC), Les Harris (Gwich'n Renewable Resource Board) and Jari Heikkila (GRRB) on the Inuvik area survey.
