ABSTRACT

Chinook salmon originating from Alaska, British Columbia, and the Pacific Northwest are harvested in the Southeast Alaska (SEAK) commercial troll and sport fisheries. Owing to its mixed stock nature, the overall SEAK Chinook salmon fishery is managed as 1 of 3 such fisheries under provisions of the Pacific Salmon Treaty (PST) Agreement. The Alaska Department of Fish and Game has used genetic mixed stock analysis to estimate the stock composition of Chinook salmon harvests in the SEAK troll and sport fisheries since 2004 based on a genetic baseline developed by the Genetic Analysis of Pacific Salmonids group for use in PST fisheries. This project estimated the relative stock composition of troll and sport fishery harvests from fishery accounting year (AY) 2016 (Oct. 1, 2015–Sept. 30, 2016). The major contributors to the SEAK troll and sport fisheries (from north to south) were the *Southeast Alaska/Transboundary River*, *North/Central British Columbia*, *West Vancouver*, *South Thompson*, *Washington Coast*, *Interior Columbia River Summer/Fall (Su/F)*, and *Oregon Coast* reporting groups. Collectively, these 7 stock aggregates accounted for 90% of the troll harvest and 94% of the sport harvest, and are referred to as *driver stocks*. The *Interior Columbia River Su/F* reporting group was the largest contributor to both the troll (39%) and sport (25%) fisheries harvest. Results indicate considerable temporal and spatial variation in the composition of troll and sport harvests in AY 2016, and changes in the relative contributions of driver stocks across years. Stock composition data from this and other stock assessments provide fisheries information including stock-specific run reconstructions and forecasting transboundary river run sizes, determining the origin of SEAK troll fishery catches by age to assist in evaluation of the Pacific Salmon Commission Chinook Model, and estimating some terminal run sizes of stocks in the PST area that drive the SEAK fishery.

Key words: Chinook salmon, Southeast Alaska, troll fishery, sport fishery, mixed stock analysis, genetic, microsatellite, Pacific Salmon Treaty

INTRODUCTION

Chinook salmon *Oncorhynchus tshawytscha* is one of the species of fish most sought after by sport anglers and the commercial troll fishing industry in Southeast Alaska (SEAK). Chinook salmon are harvested in State of Alaska and Federal Exclusive Economic Zone waters east of Cape Suckling and north of Dixon Entrance (Skannes et al. 2016). This area is divided into 4 quadrants for stock assessment purposes: Northern Outside (NO), Northern Inside (NI), Southern Outside (SO), and Southern Inside (SI) for the troll fishery (Figure 1). The sport fisheries predominantly occur around the ports of Juneau, Ketchikan, Sitka, Petersburg, Wrangell, Craig/Klawock, Yakutat, Gustavus, Elfin Cove, Skagway, and Haines (Figure 2). Both the troll and sport fisheries harvest mixed stocks[1] of Chinook salmon, including salmon originating from Alaska, British Columbia (BC), and the Pacific Northwest, and are therefore under the jurisdiction of the Pacific Salmon Treaty (PST). The principles of the PST call for cooperative management and research on fisheries harvesting Chinook salmon from populations in Canada and the U.S., and variable annual Chinook salmon harvest limits to constrain interceptions of Chinook salmon in SEAK and 2 other mixed stock fisheries along the North American coast as per PST Annexes and related Agreements (CTC 2017).

The annual all-gear harvest limit for Chinook salmon in SEAK is specified in Chapter 3, Annex IV of the PST. The majority of the PST harvest limit is allocated to the commercial troll and sport fisheries under State of Alaska management plans (i.e., the purse seine fishery is allocated 4.3% of the harvest, the gillnet fishery is allocated 2.9% of the harvest, and the setnet fishery is allocated 1,000 fish; the remaining portion of the annual harvest limit is allocated 80% to the troll fishery and 20% to the sport fishery). Thus, careful monitoring of the harvest in the troll and

[1] In this report, *population* refers to a locally interbreeding group of salmon that is distinguished by a distinct combination of genetic, phenotypic, life history, and habitat characteristics, and *stock* refers to an aggregation of 1 or more populations that occur in the same geographic area and are managed as a unit. *Reporting groups* refers to an aggregation of one or more stocks that can be identified using genetic mixed stock analysis.

sport fisheries throughout the season is essential to prevent exceeding the annual harvest limit (Pryor et al. 2009; Hagerman et al. 2017). By regulation, legal-sized Chinook salmon in the troll and sport fisheries must be 71 cm (28 inches) or greater in total length (tip of snout to fork of tail).

The annual SEAK troll harvest of Chinook salmon occurs over 3 seasonal fisheries: winter, spring, and summer. The winter fishery occurs from October 11 to April 30 of the following year, or until the guideline harvest level of 45,000 non-Alaska hatchery-produced Chinook salmon is reached. The fishery is split into *early winter* (October 11–December 31) and *late winter* (January 1–April 30) components, and the open fishing area is restricted to within the troll boundary of the outer coast surf line. The spring troll fishery (May 1 or earlier, through June 30) is managed to target Chinook salmon produced from SEAK hatcheries, many of which are exempt from the annual harvest limit. The summer troll fishery accounts for the majority of the annual Chinook salmon commercial harvest and is closely monitored and managed to prevent exceeding the troll portion of the annual harvest limit by allowing retention of Chinook salmon during 2 or more periods in most years. The first summer troll fishery opening, beginning July 1 by regulation, allows harvest in the waters of frequent high Chinook salmon abundance and is managed to not exceed 70% of the remaining troll portion of the annual harvest limit. Once the July fishery is closed, Chinook salmon retention by the troll fleet is not allowed unless it is determined that additional openings will not result in exceeding the annual harvest limit. August (and sometimes September) openings are conducted in years when it is determined that the annual harvest limit will not be exceeded. Unlike the first retention period, if additional openings occur, the waters of frequent high Chinook salmon abundance remain closed to troll gear. However, if after 10 days the department determines that the annual harvest limit for troll Chinook salmon may not be reached by September 20 with those waters closed, the waters of frequent high Chinook salmon abundance reopen.

In Accounting Year[2] (AY) 2016, the troll fishery harvested 276,432 Chinook salmon. The winter fishery harvest was 52,291 fish, of which 29,363 were caught in early winter and 22,928 were caught in late winter. The winter troll fishery closed on March 8—the earliest wintery fishery closure on record. A total of 42,782 fish were harvested in the spring fishery. The total summer fishery harvest was 181,359, of which 106,660 were caught during the first retention period in July, and 74,699 were caught during the second retention period in August and September.

The sport fishery occurs throughout the region, with highest catches around the ports of Sitka, Juneau, Ketchikan, Craig/Klawock, Petersburg, and Wrangell. Chinook salmon are targeted by sport anglers particularly in May and June as mature fish return to inside waters. The objectives of the sport fishery management plan were specified by the Alaska Board of Fisheries in 2000: (1) to manage the sport fishery to attain a harvest of 20% of the all-gear harvest limit after accounting for commercial net harvests; (2) to allow uninterrupted sport fishing in salt waters for Chinook salmon, while not exceeding the sport fishery harvest limit; (3) to minimize regulatory restriction on resident anglers not fishing from a charter vessel; and (4) to provide stability to the sport fishery by eliminating inseason regulatory changes, except those needed for conservation. In 2016, the management plan required a daily bag limit of 3 Chinook salmon for resident anglers during May and June and 2 fish daily as of July 1. The nonresident angler daily bag limit was 2 fish during May and June and 1 fish thereafter. The nonresident annual limit was 6

[2] The PST accounting year begins with the start of the winter fishery on October 11 of the previous calendar year and ends the following September; e.g., AY 2016 is October 1, 2015, through September 30, 2016.

Chinook salmon during May and June, which was reduced to 3 Chinook salmon as of July 1. In addition, residents were allowed to use 2 rods from October through March. In some designated harvest areas near hatchery release sites, bag and possession limits and annual limits were liberalized to provide increased harvest opportunity on returning Alaska hatchery Chinook salmon. The preliminary 2016 total sport harvest of Chinook salmon was 70,777 (CTC 2017).

The annual PST Chinook salmon harvest limit for SEAK depends on the projected abundance of Chinook salmon forecasted by the Chinook Technical Committee (CTC) using the Pacific Salmon Commission (PSC) Chinook Model (CTC 2017; Skannes et al. 2016). The PSC Chinook Model uses catch, escapement, coded wire tag (CWT) recovery, and recruitment information to forecast relative abundance of stocks in PST fisheries. Relative stock proportion information is an important component of the PSC Chinook Model, and currently CWT data are used for this purpose. However, reliance on stock composition estimates solely from CWT data can be problematic because CWTs are only applied to a subset of indicator stocks contributing to the fishery—most are hatchery stocks intended to represent wild stocks, and resulting escapement and terminal run size estimates are often not available or are poorly determined for many stocks outside of SEAK. Genetic mixed stock analysis (MSA) provides a complementary set of stock composition estimates for major contributors to the fishery.

Genetic MSA has been used extensively to estimate the contribution of genetic aggregates of Chinook salmon to mixed stock fisheries occurring throughout the PST area (unpublished data;[3] Hess et al. 2011; Templin et al. 2011; Beacham et al. 2012). This method uses the genetic variation in allele frequencies at multiple loci among populations (baseline) to estimate the contribution of each stock to a mixture given the multilocus genotypes of fish in the mixture. Since 1999, the State of Alaska Department of Fish and Game (ADF&G) has used MSA based on coastwide baselines (allozymes, Teel et al. 1999; microsatellites, Seeb et al. 2007) to estimate the composition of Chinook salmon harvested in the commercial troll fishery (Crane et al. 2000; Templin et al. 2011; Gilk-Baumer et al. 2013, 2017a, 2017b, *In prep*).

Genetic MSA is possible for PST fisheries due to the CTC-funded Genetic Analysis of Pacific Salmonids (GAPS) project, a cooperative project among 10 laboratories with the goal of developing a standardized DNA baseline for stock identification of Chinook salmon.[4] This process began in 2002, and a standardized baseline was available during the summer of 2005 (Seeb et al. 2007). The baseline can be used to identify 44 reporting groups in mixtures with acceptable accuracy and precision (Seeb et al. 2007). For the SEAK fisheries, the 44 reporting groups were combined into 26 reporting groups based on management needs and stock presence (Table 1). This baseline continues to be improved through the addition of populations; the current baseline (version 3.0) contains allele frequencies from 357 populations contributing to PST fisheries, ranging from the Situk River in Alaska to the Central Valley of California (Appendix A1).

---

Genetic stock identification determines inter-annual variation in stock composition for legal and sub-legal Chinook captured in the Washington Area-2 non-treaty troll fishery. Unpublished Washington Department of Fish and Wildlife molecular genetics laboratory report submitted to the Pacific Salmon Commission-Chinook Technical Committee, 2007.

4 Moran, P., M. Banks, T. D. Beacham, C. Garza, S. Narum, M. Powell, L. W. Seeb, R. L. Wilmot, and S. Young. Genetic analysis of Pacific salmonids (GAPS): Development of a standardized microsatellite DNA database for stock identification of Chinook salmon. Chinook funding proposal submitted to the US Chinook Technical Committee for funding under the budget increment associated with the US Letter of Agreement, 2004.

The expectation behind investment in genetic capabilities was that genetic MSA could be integrated into a coordinated coastwide management system, the subject of workshops held by the PSC (PSC 2008). One conclusion at the workshop was that an important advantage of genetic MSA (over CWT-based methods) is the complete coverage of all stocks and all individuals in the stocks (PSC 2008). Coded wire tags have been used for cohort analysis of individual release groups and are an integral part of the PSC Chinook Model. However, CWT-based assessments assume that the release of juvenile Chinook salmon with a CWT (usually of hatchery origin) will provide valid surrogates for a wild Chinook salmon stock of interest. Often this critical assumption is unverified and multiple studies have demonstrated that hatchery-origin fish mature and survive at rates different than their wild counterparts due to differences in growth rates, release locations, and release sizes (CTC 2015; Peterson et al. 2016). On the other hand, CWT methods are one of the only ways of detecting and estimating stocks of Chinook salmon that are minor contributors to a fishery; the numeric tags minimize the problem of misclassification and more catch is sampled for CWTs on a coastwide basis (~20%) to recover these tags. By contrast, genetic MSA is best suited for estimating contributions of major stocks, i.e., those making up relatively large proportions (≥5%) of the sample, but MSA cannot currently differentiate between hatchery and wild stocks representing the same brood source and does not include age information. While both MSA and CWT assessments are capable of providing stock composition estimates of harvest, the combination of the 2 methods is expected to be more useful.

Stocks of Chinook salmon originating from streams and hatcheries along the Southeast Alaska, Northern/Central British Columbia, West Vancouver Island, Washington, and Oregon coasts, and in the South Thompson and Upper Columbia[5] rivers, consistently contribute more than 5% to the troll and sport harvest in SEAK, and consequently are important stocks that help drive harvest allocations under the PST (Table 1; CTC 2017). Collectively these 7 aggregate stocks make up a large proportion (typically >90%; Gilk-Baumer et al. 2017a, *In prep*) of all Chinook salmon annually harvested in SEAK troll and sport fisheries, and thus genetic MSA is the preferred method for providing accurate and precise stock composition estimates for these driver stocks in SEAK fisheries (PSC 2008).

The information reported herein are the results of genetic MSA based on the most recent standardized baseline of microsatellites (GAPS version 3.0) to provide independent estimates of the stock composition of Chinook salmon harvested in the SEAK troll and sport fisheries in AY 2016. Results focus primarily on the 7 driver stocks important for SEAK fisheries managed under the PST, although information at broader and finer scales is also provided for context.

OBJECTIVES

The goal of this genetic MSA program was to estimate the stock composition of Chinook salmon harvested in SEAK commercial troll and sport fisheries during AY 2016. Project objectives were as follows.

1. Sample Chinook salmon from the SEAK troll and sport fishery harvests in a representative manner to provide stock composition estimates of the harvest within 5% of the true value 90% of the time.

[5] All summer and fall Chinook salmon transiting Bonneville Dam from June 1 through November 15, 2016, destined for areas above McNary Dam and the Deschutes River.

2. Survey Chinook salmon sampled from the SEAK troll and sport fisheries for individual genotypes at the 13 microsatellite loci in the coastwide baseline (GAPS version 3.0).
3. Estimate the relative contribution of 26 fine-scale reporting groups for the following troll fisheries in AY 2016:
    a. Early winter (October–December) and late winter (January–April) troll fisheries in the NO quadrant and across all quadrants.
    b. Spring troll fisheries (May–June) with separate estimates for Chinook salmon harvested in the NO, NI, and SI quadrants.
    c. Summer troll fisheries (July–September) with separate estimates for the first Chinook salmon opening and subsequent openings combined for Chinook salmon harvested across all quadrants and in the NO quadrant alone.
4. Estimate the relative contribution of 26 fine-scale reporting groups to SEAK sport fisheries in the following areas and time periods in AY 2016:
    a. Ketchikan, total season estimate.
    b. Petersburg-Wrangell, total season estimate.
    c. Northern Inside (ports of Juneau, Haines, and Skagway), total season estimate.
    d. Outside (ports of Craig/Klawock, Sitka, Yakutat, Elfin Cove, and Gustavus).
        i. Early season estimate (through biweek[6] 13).
        ii. Late season estimate (after biweek 13).
        iii. Total season estimate.

METHODS

FISHERY SAMPLING

The standard for precision and accuracy used by ADF&G for genetic MSA is to estimate a stock's proportional contribution within 5% of the true value 90% of the time (Seeb et al. 2000). A sample size of 400 individuals will provide estimates with the target level of precision under the worst-case scenario (3 stocks contributing equal proportions; Thompson 1987) and the department applies this standard when developing sampling programs for MSA. However, sample sizes for some strata may not meet this target size due to some combination of harvest numbers and/or sampling success. In cases where sample sizes are less than 400 and reduced precision is acceptable, estimates based on smaller sample sizes may be appropriate to inform PST-related questions. Sample sizes of 200 fish provide estimates within approximately 7% of the true value 90% of the time (Thompson 1987). Reducing sample sizes below this threshold rapidly increases uncertainty, so when strata are represented by between 100 and 199 samples, estimates are only reported for broadscale reporting groups to compensate (JTC 1997). Uncertainty associated with genetic MSA results from sample sizes below 100 fish is considered too high to provide useful information.

[6] Sport biweeks run from Monday through Sunday, with biweek 1 beginning January 1 and biweek 2 beginning on the third Monday of the year. All biweeks except the first and last of the year are exactly 14 days long. Biweek calendars for each year are available at https://mtalab.adfg.alaska.gov/CWT/reports/sbp_calendar.aspx?value=biweek (Accessed December 22, 2017).

Troll Fishery

Sample sizes were set to target a minimum 400 samples per stratum for the following 11 troll fishery strata:

1. Early winter fishery (October–December)
    a. NO quadrant
    b. Regionwide
2. Late winter fishery (January–April)
    a. NO quadrant
    b. Regionwide
3. Spring fishery (April–June)
    a. NO quadrant
    b. NI quadrant
    c. SI quadrant
4. Summer fishery (July–September)
    a. First retention period (July)
        i. NO quadrant
        ii. Regionwide
    b. Second and subsequent retention periods (August–September)
        i. NO quadrant
        ii. Regionwide

When necessary, sample goals were moved between ports within a stratum to achieve minimum sample sizes for some strata (Table 2). Sample sizes in the NO quadrant were set so that stock contributions to the harvest in this quadrant could be estimated for each of the time periods in addition to an all-quadrant estimate. Goals varied among ports depending on expectations for deliveries (processor availability), availability of port samplers, and the vagaries of each seasonal fishery.

Details regarding port sampling procedures are outlined in Buettner et al. (2017). In short, Chinook salmon were targeted for sampling from landings at processors at various SEAK ports (Table 2; Table 3; Figure 1). Fish were selected for sampling without regard to size, sex, presence of an adipose fin, or position in the vessel hold or tote; sampling was conducted in such a manner to be as representative as possible of that week's commercial catch. Axillary processes (the modified and elongated structure found at the anterior base of the pelvic fin) were excised from each fish and dried on Whatman paper. Troll fishermen were interviewed to determine the quadrant (NO, NI, SO, or SI) from which the Chinook salmon were harvested. At the end of the season, samples were shipped air cargo back to the ADF&G Gene Conservation Laboratory in Anchorage for analysis. Associated data were archived as part of the age-sex-length database maintained by ADF&G.

Sport Fishery

Sample sizes were set to target a minimum 400 samples per stratum for the following 6 sport fishery strata, with the intention of representing harvest by biweek at each port:

1. Ketchikan, total season.
2. Petersburg and Wrangell, total season.
3. Northern Inside (Juneau, Haines, Skagway), total season.

4. Outside (Craig/Klawock, Sitka, Yakutat, Elfin Cove, Gustavus):
    a. Early season.
    b. Late season.
    c. Total season.

Chinook salmon were collected from boats exiting the sport fishery at major boat harbors and boat ramps at each of the ports selected for surveying (Table 4; Figure 2). Sampling design and sampling details for each port are described in Jaenicke et al. (2015). A tissue section was dissected from the axillary process of each sampled Chinook salmon and dried on Whatman paper. Fishermen were interviewed to determine the creel port from which the Chinook salmon were harvested. At the end of the season, samples were shipped back to the ADF&G Gene Conservation Laboratory in Anchorage for analysis. Associated data were archived as part of an age-sex-length database maintained by ADF&G Division of Sport Fish.

MIXED STOCK ANALYSIS

Laboratory Analysis

Samples were assayed for 13 microsatellite loci developed by the GAPS group for use in PST fisheries (CTC standardized baseline loci; Seeb et al. 2007). Genomic DNA was extracted from tissue samples using a NucleoSpin 96 Tissue Kit by Macherey-Nagel (Düren, Germany). Polymerase chain reaction (PCR) was carried out in 10 ul reaction volumes (10 mM Tris-HCl, 50 mM KCl, 0.2 mM each dNTP, 0.5 units Taq DNA polymerase [Promega, Madison, WI]) using an Applied Biosystems (AB; Foster City CA) thermocycler. Primer concentrations, $MgCl_2$ concentrations, and the corresponding annealing temperature for each primer are available in Seeb et al. 2007. PCR fragment analysis was done on an AB 3730 capillary DNA sequencer. A 96-well reaction plate was loaded with 0.5 ul PCR product along with 0.5 ul of GS500LIZ (AB) internal lane size standard and 9.0 ul of Hi-Di (AB). PCR bands were visualized and separated into bin sets using AB GeneMapper software v4.0. All laboratory analyses followed protocols accepted by the CTC.

Genetic data were collected as individual multilocus genotypes. According to the convention implemented by the CTC, at each locus a standardized allele is one that has a recognized holotype specimen from which the standardized allele can be reproduced using commonly applied fragment analysis techniques. By the process of sizing the alleles from the holotype specimens, any individual laboratory should be able to convert allele sizes obtained in the ADF&G laboratory to standardized allele names. Genotype data were stored as GeneMapper (*.fsa) files on a network drive that was backed up nightly. Long-term storage of the data was in an *Oracle* database (*LOKI*) on a network drive maintained by ADF&G computer services.

Several measures were implemented to ensure the quality of data produced. First, each individual tissue sample was assigned a unique accession identifier. At the time DNA was extracted or analyzed from each sample, a sample sheet was created that linked each individual sample's code to a specific well number in a uniquely numbered 96-well plate. This sample sheet then followed the sample through all phases of the project, minimizing the risk of misidentification of samples through human-induced errors. Second, genotypes were assigned to individuals using a system in which 2 people score the genotype data independently. Discrepancies between the 2 sets of scores were then resolved with 1 of 2 possible outcomes: 1 score was accepted and the other rejected, or both scores were rejected and no score was retained. Lastly, 8 samples from each 96-well DNA extraction plate were reanalyzed for all loci. This enabled detection and correction of laboratory mistakes and also allowed for estimation of genotyping error rates. Error rates were calculated as the number of conflicting genotypes, divided by the total number of genotypes examined.

Statistical Analysis

Troll Fishery Mixture Subsampling

Representative mixtures of individuals for MSA were created by subsampling individuals from the collected tissue samples in proportion to harvest by quadrant. The harvest of Chinook salmon in each quadrant for a given troll fishery opening was obtained from the ADF&G Mark, Tag, and Age Laboratory website (https://mtalab.adfg.alaska.gov/CWT/reports/default.aspx) using the criteria in Table 5. The relative proportion of the total period harvest that was caught in each quadrant was then calculated for each fishery opening.

Eleven mixtures were necessary to generate stock composition estimates for the strata described above. For each fishery/quadrant stratum, individual samples were randomly selected from the entire set of samples. When a stratum was made up of multiple quadrants, individual samples were randomly selected from the entire set of samples in proportion to harvest in each quadrant. For regionwide (all quadrant) estimates, separate mixtures were made to estimate stock contributions for both the NO quadrant and all other quadrants combined. These separate estimates were then pooled into regionwide estimates by weighting by harvest (Templin et al. 2011). When sufficient samples were available, the target sample size for each mixture was 400. When fewer than 400 individuals were available, the maximum number of available samples was used with a minimum sample size of 100 fish. Estimates were generated for samples of 100–199 fish, but only for the broadscale reporting groups outlined in Table 1. No estimates were generated for sample sizes less than 100.

Sport Fishery Mixture Subsampling

Representative mixtures of individuals for MSA were created by subsampling individuals from the collected tissue samples in proportion to harvest by time and sample location (e.g., biweek and port). The inseason estimated Chinook salmon harvest for each biweek and port for a given fishing area was obtained from onsite sampling of sport harvested Chinook salmon by the Division of Sport Fish Southeast Alaska Marine Harvest Studies program (Wendt and Jaenicke 2011; Jaenicke et al. 2015). The total harvest for each port is estimated by the annual Division of Sport Fish Statewide Harvest Survey mailout (Jennings et al. 2015; Romberg and Jennings 2013), which can be downloaded at http://www.adfg.alaska.gov/sf/sportfishingsurvey/. The relative proportion of the total harvest that was caught during each biweek and in each port was then calculated for each fishing area.

A total of 5 mixtures were necessary to generate stock composition estimates for the 6 sport fishery strata described above. For each time period/port stratum, individual samples were randomly selected from the entire set of samples from that biweek and port. When a stratum was made up of multiple time periods or ports, individual samples were randomly selected in proportion to harvest in each period or port. For the total season estimate for Outside ports, separate mixtures were made to estimate stock contributions for the early (through biweek 13) and late (after biweek 13) periods. These estimates were then pooled into total season estimates by weighting by harvest for each time period's harvest. When sufficient samples were available, the target sample size for each mixture was capped at 400. When the available samples from a given biweek and/or port were fewer than needed to adequately represent the quadrant in a mixture of 400, the total sample size was reduced to the point where each biweek and port was represented in the proportional to harvest. When fewer than 400 individuals were available for sport fishery estimates, a minimum sample of 200 fish was used and there was no weighting for harvest.

BAYES Analysis

The stock composition of fishery mixtures were estimated using the program BAYES (Pella and Masuda 2001). The Bayesian method of MSA is used to estimate the proportion of stocks caught within each fishery using 4 pieces of information: (1) a baseline of allele frequencies for each population, (2) the grouping of populations into the reporting groups desired for MSA, (3) prior information about the stock proportions of the fishery, and (4) the genotypes of fish sampled from the fishery.

The baseline of allele frequencies for Chinook salmon populations was obtained from the GAPS database (http://www.nwfsc.noaa.gov/research/divisions/cb/genetics/standardization.cfm). Results from 100% proof tests indicate that the fine-scale reporting groups used herein can be identified in mixtures with a 91% correct allocation or better (Gilk-Baumer et al. 2017b).

The choice of prior information about stock proportions in a fishery (the prior probability distribution hereafter referred to as the *prior*) is important for increasing MSA accuracy (Habicht et al. 2012a). In this analysis, the estimated stock proportions from the previous year in a given stratum were used as the prior for that stratum (i.e., 2015 estimates were used as prior parameters when generating 2016 estimates). The prior information about stock proportions was incorporated in the form of a Dirichlet probability distribution. The sum of all prior parameters was set to 1 (prior weight), which is equivalent to adding 1 fish to each mixture (Pella and Masuda 2001).

For each fishery mixture, 5 independent Markov Chain Monte Carlo chains of 40,000 iterations were run with different starting values and the first 20,000 iterations were discarded to remove the influence of the start values. We assessed the within- and among-chain convergence of estimates using the Raftery-Lewis (within-chain) and Gelman-Rubin (among-chain) diagnostics. These values measure the convergence of each chain to stable estimates (Raftery and Lewis 1996) as well as measure the variation of estimates within a chain to the total variation among chains (Gelman and Rubin 1992), respectively. If a Gleman-Rubin diagnostic for any stock group in a mixture was greater than 1.2, the mixture was reanalyzed with 80,000 iterations. If a mixture still had a diagnostic greater than 1.2 after the reanalysis, results from the 5 chains were averaged and a note was made in the results. We combined the second half of the 5 chains to form the posterior distribution and tabulated mean estimates, 90% credibility intervals, and standard deviations from a total of 100,000 iterations. In addition, we report the marginal median of the posterior distribution as a measure of central tendency for stock proportions (Pella and Masuda 2001). Misallocations to reporting groups that are either absent or at low proportions within mixtures can occur in MSA when the discriminant methods do not produce perfect identifiability (Pella and Milner 1987; Pella and Masuda 2001). Previous work has shown that the posterior distribution of these misallocations can be highly skewed and the mean is much more sensitive to extreme values than the median (e.g., Habicht et al. 2012b). Both means and medians are reported in appendix tables and means are reported in figures and in the text.

For regionwide estimates for the winter and summer troll fisheries, estimates from the NO quadrant and all other quadrants combined were pooled into total area estimates by weighting each quadrant's estimate by their respective harvests (stratified estimator). Similarly, for sport fishery total season estimates from the Outside area, early season and late season estimates were pooled into yearly estimates by weighting each season's estimate by their respective harvest proportions (stratified estimator). This analysis is described in detail in Templin et al. (2011).

In order to better describe annual trends across a longer time frame for those stocks that make up the largest proportion of harvest in SEAK Chinook salmon fisheries (i.e., the driver stocks), the 26 fine-scale reporting groups were condensed into 8 reporting groups that consisted of 7 driver stocks and an *Other* group (Table 1). Where possible, these reporting groups were aligned with stock groups used by the CTC for the PSC Chinook Model, and these groups perform well in genetic MSA. Further, the fine-scale groups were combined into 4 broadscale reporting groups for describing trends on a large geographic scale (Table 1). When reporting groups were combined, credibility intervals were calculated from the raw BAYES output using the new groupings in order to accurately reflect uncertainty in the estimates.

These reporting groups are large and in some situations do not provide the desired resolution. To enable accurate and precise investigation at a finer scale and to improve visualization of results, proportional contributions are also provided graphically for a subset of the fine-scale reporting groups estimated to consistently contribute at least 5% to the harvest in at least 1 seasonal fishery per year. Again, all other stocks are included in an additional *Other* group, and credibility intervals were calculated from the raw BAYES output using the new groupings.

RESULTS

FISHERY SAMPLING

Troll Fishery

A total of 6,193 tissue samples were collected across all seasonal troll fisheries in AY 2016, which exceeds the sampling goal of 4,915. Goals were generally met for all fishery periods, but missed at some ports (Table 2). This was primarily a result of reduced fishing effort or less intensive harvest sampling during some seasonal fisheries.

Sampling of Chinook salmon during the winter fisheries began with the early winter opening on October 11, 2015, and continued until the late winter fishery closed March 8, 2016. The sampling goals for winter fisheries by port are heavily weighted towards Sitka (70%) where the majority of the seasonal harvest occurs (typically 60–65%). A total of 557 samples (goal: 545) were collected from the early winter troll fisheries and 576 samples (goal: 550) were collected from the late winter troll fisheries. Goals were met for every port in the early winter and in the late winter except for Ketchikan.

Sampling of Chinook salmon during the spring troll fishery occurred between April and June. Sample goals were met for every port except Yakutat (Table 2). The sample size was only 186 from the NI quadrant; therefore, estimates were only generated to the 4 broadscale reporting groups (Table 1).

Sampling of Chinook salmon during the first retention period of the summer troll fishery occurred July 1–5. Sample goals were met for every port except Yakutat, Juneau, Ketchikan, and Port Alexander, and exceeded in Craig, Elfin Cove, Petersburg, Pelican, and Wrangell (Table 2).

The total sample size of 1,710 was sufficient to generate estimates to the fine-scale reporting groups for both the NO quadrant and regionwide strata.

Sampling of Chinook salmon during the second retention period of the summer troll fishery occurred from August 13 to September 3. Sample goals were met in all ports except Port Alexander, Wrangell, and Yakutat, and exceeded in Craig, Elfin Cove, Ketchikan, Pelican, Petersburg, and Sitka. The total sample size of 1,632 was sufficient to generate estimates to the fine-scale reporting groups for both the NO quadrant and regionwide strata.

Sport Fishery

Sampling of Chinook salmon from SEAK sport fisheries began in April and ended in September. A total of 4,499 tissue samples (goal: 4,075) were collected across 6 months of the sport fishing season in 2016. Goals were generally met for most ports (Table 4). Reduced fishing effort, harvest sampling rates, and in some cases, poor Chinook salmon abundance were primary reasons for not attaining sampling goals.

In Ketchikan, the total sample size of 799 exceeded the goal of 600. This sample size was sufficient to generate estimates to the fine-scale reporting groups for the Ketchikan area.

A total of 321 samples (goal: 450) were collected from Petersburg and 136 samples (goal: 200) were collected from Wrangell (Table 4). The combined total of 457 tissues was sufficient to generate estimates to the fine-scale reporting groups for the Petersburg-Wrangell area.

The sampling goals for Northern Inside fisheries by port are heavily weighted towards Juneau (95%) where the vast majority of the fishing effort is concentrated. The total sample size of 324 was below the sampling goal of 635, but was sufficient to generate estimates to the fine-scale reporting groups. No samples were taken in Haines or Skagway due to reduced fishing in AY 2016.

For Outside fisheries, a total of 1,993 samples (goal: 1,375) were collected from biweeks 9–13 and 926 samples (goal: 815) were collected from biweeks 14–18 (Table 4). Sample goals were met or exceeded for every port except Yakutat (biweeks 9–13) and Yakutat and Sitka (biweeks 14–18).

MIXED STOCK ANALYSIS

Laboratory Analysis

Quality control demonstrated a low error rate for all samples analyzed. A total of 690 fish were examined for quality control, or 8,970 genotype comparisons. The discrepancy rate was 0.10% over all projects. This translates to an estimated error rate of 0.05%.

Statistical Analysis

Early Winter Troll Fishery

For broadscale reporting groups, the *US South* group (stocks originating from California, Oregon and Washington) was the highest contributor during the regionwide early winter troll fishery in AY 2016 (54%), followed by the *Canada* (33%) and *Alaska* (12%) groups. The *Transboundary* (*TBR*) group had a low contribution (<1%; Appendix B1).

For driver stock reporting groups, the largest contributor to the regionwide early winter troll fishery was the *Interior Columbia River Su/F* group (41%), followed by the *Other* (21%), *North/Central British Columbia* (*NCBC*; 20%), and *SEAK/TBR* (13%) groups (Figure 3; Appendix B2).

For the fine-scale reporting groups, the largest contributors to the regionwide early winter troll fishery were the *Interior Columbia Su/F* (41%), *BC Coast/Haida Gwaii* (18%), *S Southeast Alaska* (9%), and *East Vancouver* (9%) groups (Figure 4; Appendix B3).

When considering harvest from the NO quadrant only, the contributions for driver stock reporting groups were similar; the *Interior Columbia River Su/F* group was the largest contributor (47%), followed by the *Other* group (21%).

Late Winter Troll Fishery

For broadscale reporting groups, the *Canada* group was the highest contributor during this fishery (48%), followed by the *US South* (41%) and *Alaska* (10%) groups. The *TBR* group had a low contribution (<1%; Appendix B1).

For driver stock reporting groups, the largest contributor to the regionwide late winter troll fishery was the *Other* group (25%), followed by the *Interior Columbia Su/F* (22%), *NCBC (21%)*, *West Vancouver* (19%), and *SEAK/TBR* (11%) groups (Figure 3; Appendix B2).

For the fine-scale reporting groups, the largest contributor to the regionwide late winter troll fishery was the *Interior Columbia River Su/F* group (22%), followed by the *West Vancouver* (19%), *BC Coast/Haida Gwaii* (19%), *Willamette Sp* (12%), *S Southeast Alaska* (8%), and *East Vancouver* (6%) groups (Figure 5; Appendix B4).

When considering harvest from the NO quadrant only, the contributions for driver stock reporting groups were similar to regionwide estimates, except the *Interior Columbia Su/F* group was the largest contributor (27%), followed closely by the *Other* (26%) group (Figure 3; Appendix B2). The *NCBC* (20%) and *West Vancouver* (18%) groups were also sizeable contributors.

Spring Troll Fishery

During the spring troll fisheries, contributions of the broadscale reporting groups were highly variable across the 4 quadrants analyzed. In the NO quadrant, the *Canada* group was the highest contributor (42%), followed by the *US South* (34%) and *Alaska* groups (23%; Appendix B1). In the NI quadrant, the *Canada* group was the highest contributor (43%), followed by the *Alaska* (32%) and the *TBR* (15%) groups. In the SO quadrant, the *Canada* group contributed the majority of the harvest (62%), followed by the *Alaska* (22%) and the *US South* (15%) groups. Conversely, in the SI quadrant the *Alaska* group contributed the majority of the harvest (53%), followed by the *Canada* (29%) and *US South* (15%) groups. The *TBR* group had a low contribution (range: <1–3%) across all quadrants except the NI quadrant (15%).

For the driver stock reporting groups, contributions were also variable amongst quadrants during the spring troll fisheries. The largest contributor to the NO quadrant harvest was the *SEAK/TBR* group (25%), followed by the *Interior Columbia Su/F* (23%), *West Vancouver* (20%), *NCBC* (13%), and *Other* (13%) groups (Figure 3; Appendix B2). In the SI quadrant, the largest contributor was also the *SEAK/TBR* group (56%), followed by the *NCBC* (16%) and *Interior Columbia Su/F* (9%) groups.

For the fine-scale reporting groups, similar variability between quadrants was observed. In the NO quadrant, the highest proportion of Chinook salmon was from the *Interior Columbia Su/F* group (23%), followed by the *West Vancouver* (20%) group (Figure 6; Appendix B5). The *Alaska* component was largely composed of the *Andrew* group (17%), which includes production from the 5 hatcheries that use Andrew Creek broodstock. The *Canada* group contribution was dominated by *West Vancouver* (20%), followed by the *BC Coast/Haida Gwaii* (12%) group. In the SI quadrant, the *Alaska* group was the largest contributor with harvests dominated by the *S Southeast Alaska* group (37%), followed by the *Andrew* (17%) group. The *BC Coast/Haida Gwaii* group was the next highest contributor (15%).

In the NI and SO quadrants, estimates are not available for either the driver stock reporting groups or 26 fine-scale reporting groups because sample sizes were insufficient for meeting the accuracy and precision standards.

Summer Troll Fishery, First Retention Period

For broadscale reporting groups during the first retention period of the summer troll fishery, the *US South* reporting group accounted for the vast majority of the regionwide harvest (77%), followed by the *Canada* (21%) group. The *Alaska* group had a low contribution (<3%) and the *TBR* group had an even lower contribution (<1%; Appendix B1).

For driver stock reporting groups, the greatest contributor to the regionwide harvest during the first retention of the summer troll fishery was the *Interior Columbia Su/F* group (45%), followed by the *Oregon Coast* (18%) and *South Thompson* (13%) groups (Figure 3; Appendix B2).

For the fine-scale reporting groups, the first retention period of the summer troll fishery was dominated by the *Interior Columbia Su/F* group (45%), followed by the *North Oregon Coast* (16%) and *South Thompson* (13%) groups. The *Washington Coast* and *Lower Columbia F* groups contributed approximately equal proportions (~6%) to the regionwide harvest (Figure 7; Appendix B6).

Stock composition in the NO quadrant during the first retention period was similar to estimates for the entire area at the driver stock level of reporting groups, with harvests dominated by the *Interior Columbia (Su/F)* group (47%; Figure 3; Appendix B2). The *Oregon Coast* (19%), *South Thompson* (11%), *Other* (8%), and *Washington Coast* (7%) groups were also substantial contributors.

Summer Troll Fishery, Second Retention Period

For broadscale reporting groups during the second retention period of the summer troll fishery, the *US South* group accounted for the vast majority of the harvest (77%), followed by the *Canada* (19%) group. The *Alaska* group had a low contribution (<4%) and the *TBR* group had no discernable contribution (<0.001%; Appendix B1).

For driver stock reporting groups, the greatest contributor to the regionwide harvest during the second retention of the summer troll fishery was the *Interior Columbia Su/F* group (48%), followed by the *Oregon Coast* (18%), *West Vancouver* (9%), and *Washington Coast* (8%) groups (Figure 3; Appendix B2).

For the fine-scale reporting groups, the second retention period of the summer troll fishery was dominated by the *Interior Columbia Su/F* group (48%), followed by the *North Oregon Coast* (16%), *West Vancouver* (9%), *Washington Coast* (8%), and *South Thompson* (5%) groups. All other individual reporting groups contributed less than 3% (Figure 8; Appendix B7).

Stock composition in the NO quadrant during the second retention period was similar to estimates for the entire area at the driver stock level of reporting groups, with harvests dominated by the *Interior Columbia Su/F* group (50%; Figure 3; Appendix B2). Also important were the *Oregon Coast* (15%), *West Vancouver* (10%), *Washington Coast* (9%), and *South Thompson* (6%) groups.

Ketchikan Area Sport Fishery

For broadscale reporting groups, the *Alaska* reporting group accounted for the majority of the Ketchikan area sport fishery harvest (56%), followed by the *Canada* (33%) and *US South* (11%) groups. The *TBR* group had a low contribution (<1%; Appendix B8).

For driver stock reporting groups, the greatest contributor to the Ketchikan area sport fishery harvest was the *SEAK/TBR* reporting group (57%), followed by the *NCBC* (15%), *South Thompson* (9%), and *West Vancouver* (8%) groups (Figure 9; Appendix B9).

Stock contribution in the Ketchikan area sport fishery harvest for the fine-scale reporting groups was dominated by the *S Southeast Alaska* group (56%; Figure 10; Appendix B10). The *South Thompson* and *BC Coast/Haida Gwaii* groups contributed equal proportions (~9%), followed by the *West Vancouver* (8%) and *Interior Columbia Su/F* (7%) groups. No other stocks were present at greater than 5% in this fishery.

Petersburg-Wrangell Area Sport Fishery

For broadscale reporting groups, the *Alaska* reporting group was the largest contributor to the Petersburg-Wrangell area sport fishery harvest (49%), followed by the *Canada* (26%) and *TBR* (24%) groups. The *US South* aggregate had a low contribution (<2%; Appendix B8).

For driver stock reporting groups, the greatest contributor to the Petersburg-Wrangell area sport fishery harvest was the *SEAK/TBR* group (73%), followed by the *NCBC* (22%) group (Figure 9; Appendix B9).

The largest contributor among the fine-scale reporting groups to the sport fishery harvest in the Petersburg-Wrangell area was the *Andrew* reporting group (33%), which is primarily production from hatcheries that use Andrew Creek broodstock (Figure 10; Appendix B10). Other important contributors were the *Stikine* (16%), *S Southeast Alaska* (15%), *Skeena* (11%), *BC Coast/Haida Gwaii* (11%), and *Taku* (9%) groups. Note that estimated contributions did not converge at 80,000 iterations in BAYES and the results reported herein are an average of the estimates generated from 5 chains.

Northern Inside Area Sport Fishery

For broadscale reporting groups, the *Alaska* group was the largest contributor to the Northern Inside area sport fishery harvest (52%), followed by the *TBR* (33%) and *Canada* (13%) groups. The *US South* aggregate had a low contribution (<3%; Appendix B8).

For driver stock reporting groups, the greatest contributor to the Northern Inside area sport fishery harvest was the *SEAK/TBR* reporting group (85%), followed by the *NCBC* (11%) group (Figure 9; Appendix B9).

Sport fishery harvests in the Northern Inside area at the fine scale were dominated by local stocks (Figure 10; Appendix B10). The largest contributor was the *Andrew* reporting group

(47%), followed by the *Taku* (33%) group. Very few fish from stocks south of Alaska were present with the exception of the *BC Coast/Haida Gwaii* group (7%).

Outside Area Sport Fishery

For broadscale reporting groups, the *US South* reporting group was the largest contributor to the Northern Outside area all-season sport fishery harvest (48%), followed by the *Canada* (45%) and the *Alaska* (6%) groups (Appendix B8). In the early season, the *US South* reporting group was the largest contributor (51%), followed by the *Canada* (41%) and *Alaska* (8%) groups. In the late season, the *Canada* group accounted for the majority of the harvest (56%), followed by the *US South* (41%) group. The *TBR* group had no discernable contribution during any of the time periods analyzed (0%).

For driver stock reporting groups, the greatest contributor to the Outside area sport fishery harvest was the *Interior Columbia Su/F* reporting group (30%), followed by the *West Vancouver* (25%), *South Thompson* (10%), *NCBC* (9%), and *Washington Coast* (6%) groups (Figure 9; Appendix B9).

The largest fine-scale contributor to the sport fishery over the entire season to the Outside area was the *West Vancouver* reporting group (34%), followed by the *Interior Columbia Su/F* (27%) group (Figure 11; Appendix B11). The *Washington Coast* (8%), *BC Coast/Haida Gwaii* (7%), *South Thompson* (7%), and *Skeena* (5%) groups were also notable contributors.

Similar results were obtained when comparing early and late season estimates in the Outside area for the driver stock reporting groups. In the early season, the *Interior Columbia Su/F* reporting group dominated the harvest (32%), followed by the *West Vancouver* (22%), *South Thompson* (11%), *SEAK/TBR* (8%), *NCBC* (7%), and *Oregon Coast* (7%) groups (Figure 9; Appendix B9). During the late season, the *West Vancouver* (35%) and *Interior Columbia Su/F* (26%) groups were the largest contributors, followed by the *NCBC* (13%), *Washington Coast* (8%), and *South Thompson* (7%) groups.

DISCUSSION

Genetic MSA has been successfully used to estimate the composition of the commercial troll fishery harvest since 1999 (e.g., Gilk-Baumer et al. 2013, 2017a, 2017b, *In prep*). Because the 7 aggregate driver stocks make up the vast majority (>90%) of all Chinook salmon annually harvested in SEAK troll and sport fisheries, these stock aggregates influence the harvest allocations under the PST (Gilk-Baumer et al. 2013, 2017a, 2017b, *In prep*). Genetic MSA is the preferred method to provide accurate and precise harvest estimates for these large aggregates of driver stocks. These estimates indicate that the composition of the harvest varies spatially and by seasonal fishery, but essentially the same constituent stocks are present year to year (Gilk-Baumer et al. 2017a, 2017b, *In prep*).

INTRA-ANNUAL VARIABILITY

Temporal Variability

Comparison of the composition of harvests among seasonal troll fisheries in AY 2016 shows considerable variability (Figure 3). The composition of early and late winter fisheries includes a mixture of more stocks than other seasonal fisheries, and the 7 driver stocks account for 79% of the early harvest and 75% of the late harvest. Both winter fisheries were heavily dominated by the *Columbia Su/F*, *NCBC*, *West Vancouver*, and *SEAK/TBR* driver stocks; other notable contributing reporting groups were *East Vancouver* and *Willamette Sp*. By contrast, during the spring troll fishery, when fishing effort is directed at harvesting SEAK-origin hatchery stocks, the contribution of SEAK-origin Chinook salmon (hatchery-origin plus natural-origin) was 36%, considerably higher than at other times of the year. More than 90% of the spring harvest composition was accounted for by the 7 driver stocks. The harvest composition in the first retention period of the summer troll fishery was heavily dominated by the *Interior Columbia Su/F* (45%), *Oregon Coast* (18%), and *South Thompson* (13%) driver stocks; overall 92% of harvest was contributed by driver stocks. Because the majority of the annual harvest limit was taken during the first retention period of the summer troll fishery in AY 2016, these 3 stocks still contributed substantially to the annual harvest (58%; Figure 12). Similarly, the second retention period of the summer troll fishery was heavily dominated by the *Interior Columbia Su/F* (48%) and *Oregon Coast* (18%) driver stocks, but also had sizeable contributions from the *West Vancouver* (9%) and *Washington Coast* (8%) stocks; 94% of the harvest in the second summer troll retention period is attributable to driver stocks.

Similarly, the stock composition of the Outside area sport fishery harvest also shows seasonal variability (Figure 9). In the early season, the *Interior Columbia Su/F* was the dominant reporting group (32%), followed by the *West Vancouver* (22%) and *South Thompson* (11%) groups. In contrast, the largest contributor to the late season sport fishery was the *West Vancouver* group (35%), followed by the *Interior Columbia Su/F* (26%) and *Washington Coast* (8%) reporting groups. For the early season fishery in AY 2016, 92% of the harvest is attributable to driver stocks, whereas the late season fishery harvest was composed of 95% driver stocks.

Differences in stock composition between troll and sport fisheries may also be due to the timing of the fisheries. In the sport fishery, 95% of the harvests in SEAK occur annually between April and August; by contrast, the troll fishery harvest is spread throughout most of the year. The early season sport fishery tends to harvest a higher proportion of northern stocks than the late season fishery.

Although the 7 driver stocks accounted for the vast majority of the harvests in AY 2016, the proportional contribution of each stock varied across seasons. *Interior Columbia Su/F* stocks accounted for large proportions of the harvest in all seasonal fisheries in AY 2016 and were particularly large contributors during winter and summer troll fisheries and Outside area sport fisheries (Figure 3; Figure 9). The *SEAK/TBR* driver stock aggregate was the dominant contributor to spring troll fisheries and present in low proportions for other seasonal fisheries; this reporting group was also more prevalent in early season (biweeks 9–13) than late season (biweeks 14–18) Outside area sport fisheries (Figure 3; Figure 9). The *NCBC* driver stock aggregate was most pronounced in early winter and late winter troll fisheries and was also a notable contributor to the spring troll fishery; in the Outside area sport fishery it contributed more to early season harvests than to late season harvests. The *West Vancouver* driver stock was most pronounced in late winter and spring troll fisheries and late season Outside area sport fisheries. Driver stocks originating from the *South Thompson*, *Washington Coast*, and *Oregon Coast* contributed substantially to the summer troll fishery particularly in the NO quadrant, but were virtually absent in winter and spring fisheries, and were similarly absent across early and late season Outside area sport fisheries.

Spatial Variability

Variation in stock composition also occurs spatially among the troll fishery quadrants. In general, stock contribution estimates based on samples from the NO quadrant had the most diverse stock compositions and the highest proportion of stocks originating south of Alaska (Figures 4–8). This was most pronounced in the spring fishery where the SI quadrant had the highest proportion of *Alaska* and *TBR* stocks harvested (56%), and the proportion of those stocks in the NO quadrant was 25% (Appendix B1). For winter and summer fisheries, stock contribution estimates based on samples from the NO quadrant were similar to estimates based on samples from all quadrants (Figures 4, 5, 7 and 8). This probably reflects the high proportion of fish harvested in this quadrant relative to the other quadrants.

The stock composition of sport fishery harvests also varies greatly by area (Figure 10). The fisheries located in inside waters (the Northern Inside, Petersburg-Wrangell, and Ketchikan areas) were made up primarily of *Alaska* and *TBR* stocks (Figure 10). Local stocks were the major contributors to fisheries in each of these areas, with more northern (*Alaska* and *TBR*) stocks present in the Northern Inside fishery, and the prevalence of nonlocal stocks originating from south of the Alaska/Canada border increasing in the more southern areas of Southeast Alaska. The Northern Inside fishery takes place near the ports of Juneau, Haines, and Skagway; these ports are in close proximity to the origin of stocks that make up the *N Southeast Alaska* and *Taku* reporting groups. In addition, the *Andrew* reporting group is the broodstock for many hatchery stocks, including the Macaulay Hatchery located in Juneau. The *Andrew* (47%) and *Taku* (33%) reporting groups were the largest contributors to the Northern Inside fishery harvest. The *N Southeast Alaska* accounted for a small share of the harvest (<2%; Figure 10). The largest contributors to the Petersburg-Wrangell area fishery were the local *Andrew* (33%) and *Stikine* (16%) reporting groups (Figure 10); moreover, *Andrew* is the broodstock used in nearby Crystal Lake Hatchery. The largest contributor to the Ketchikan fishery was the *S Southeast Alaska* reporting group (56%; Figure 10), which includes 14 nearby populations. Very few non-Alaskan or nontransboundary groups were represented in these inside fisheries.

In contrast to inside areas, Chinook salmon sport fishery harvests that took place in the Outside area were made up of a greater variety of stocks with many more fish from non-Alaska reporting groups (Figure 11). This is similar to the spatial pattern of catch composition observed in troll fisheries occurring in outside quadrants (Figure 3; Figure 9). Although the sport fishery is more protracted and occurs closer to shore when compared to each seasonal commercial troll fishery, there is overlap in timing and location with the spring and summer commercial troll fisheries that allows comparison of represented reporting groups. Both the sport fishery and the NO quadrant troll fishery harvest a variety of stocks, and the same reporting groups (*SEAK/TBR*, *NCBC*, *West Vancouver*, *South Thompson*, *Washington Coas*t, *Interior Columbia Su/F*, and *Oregon Coast*) are prevalent in both fisheries. For the Ketchikan area sport fishery and SI quadrant spring troll fishery, the contributions of driver stocks were nearly identical to the broadscale reporting groups in 2016 (Figure 3; Figure 9), although they were made up of different fine-scale reporting groups (Figure 6; Figure 10). By contrast, the NO quadrant spring troll fishery had much higher proportions of northern stock groups than the early season Outside area sport fishery (biweeks 9–13), including the *SEAK/TBR* (25% troll, 7% sport) and *NCBC* (13% troll, 7% sport) groups; whereas the sport fishery had higher proportions of southern stock, including the *WAC* (2% troll, 6% sport), *Interior Columbia Su/F* (23% troll, 32% sport), and *Oregon Coast* (3% troll, 7% sport) groups (Appendix B6; Appendix B11).

However, the late season Outside area sport fishery (biweeks 14–18) harvested a higher proportion of fish from northern stocks compared to the NO quadrant summer troll fishery, including the *NCBC* (1% troll, 13% sport) *West Vancouver* (4% troll, 35% sport) groups (Figure 3; Figure 9). The NO quadrant summer troll fishery consistently harvested higher proportions of fish from southern stocks, including the *South Thompson* (11% troll, 7% sport), *Interior Columbia Su/F* (47% troll, 26% sport), and *Oregon Coast* (19% troll, 3% sport) groups. These differences are likely due to sport anglers typically fishing closer to the coastline and commercial troll fishers operating well offshore in some cases.

INTERANNUAL TRENDS

Under the current PST fishing regime, some interesting trends can be observed in the composition of SEAK troll and sport fisheries from both the data reported herein and in similar studies dating back to AY 2009 (Gilk-Baumer et al. 2013, 2017a, 2017b, *In prep*). When making inferences on the relative contributions of each stock group to the overall harvest by fishery, it is important to note that, on an annual basis, the troll fishery harvests substantially more fish than the sport fishery (Figure 11). In general, the trend across most fisheries in recent years has been an increasing prevalence of *Interior Columbia Su/F* stocks and a decreasing prevalence of *SEAK/TBR* stocks (Figure 11; Appendix B12; Appendix B13). This is most pronounced in fisheries occurring in the NO quadrant of the troll fishery and the Outside area of the sport fishery. These trends correspond with an increase in productivity of *Interior Columbia Su/F* stocks, which accounted for 39% of the total season troll harvest and 25% of the total season sport harvest in AY 2016. This increase was mirrored by a decrease in productivity for *SEAK/TBR* stocks. The proportion of the *N Southeast Alaska* stock group in the NI quadrant of the troll fishery and the NI area of the sport fishery across years was much lower than that observed in recent years (Gilk-Baumer et al. 2017a, 2017b, *In prep*); this corresponds to decreases in escapements, terminal run sizes, and decreased productivity for the constituent stocks (CTC 2017). Similarly, the presence of the *S Southeast Alaska* reporting group harvested in the SI quadrant of the troll fishery and the Ketchikan area of the sport fishery was notably lower than in recent years (Gilk-Baumer et al. 2017a, 2017b, *In prep*). This decrease coincides with lower escapements to the Unuk, Keta, Blossom, and Chickamin rivers, and decreased survival of Chinook salmon hatchery stocks in the southern portion of Southeast Alaska. Consequently, additional management actions were taken during the spring troll fishery in AY 2016 in the form of time and area closures to protect these stocks (Hagerman et al. 2017). Stocks originating from *West Vancouver* contributed a below average proportion to the troll fishery harvest (8%; Appendix B9) and an above average proportion to the sport fishery (21%; Appendix B13) in AY 2016. The contributions from *Washington Coast* and *Oregon Coast* stocks remained more consistent from 2009 to 2016 in both troll and sport fisheries, whereas contributions from *NCBC* and *South Thompson* were more variable across years with no discernable pattern (Figure 3; Figure 9).

Specific comparisons between analyses using the most recent microsatellite baseline (GAPS version 3.0, Gilk-Baumer et al. 2017a, 2017b, *In prep*), those using older microsatellite baselines (GAPS version 2.2; 2004–2009, Gilk-Baumer et al. 2013) and those using allozyme baselines (1999–2003, Templin et al. 2011) can be made, but they must be interpreted carefully because both the number of populations and reporting groups changed between the studies. Because of these changes in the genetic baselines, comparisons across years prior to 2010 are more reliable at the broad scale than at fine-scale levels.

APPLICATIONS TO PACIFIC SALMON TREATY

These results provide a comprehensive assessment using MSA to estimate the stock composition of Chinook salmon harvested in SEAK troll and sport fisheries. Stock composition data from this program are currently being used in several other studies with a broad array of applications.

1. These MSA stock composition estimates have already proven valuable for fishery management in terminal and near-terminal areas and are being used in run reconstructions to generate more accurate stock assessments for transboundary rivers under Chapter One of the PST.
2. These MSA stock composition estimates are being combined with individual assignment, otolith mark, CWT, age, and harvest information to provide independent abundance estimates of some PSC Chinook Model stocks to assist in evaluation of the PSC Chinook Model. The current PSC Chinook Model does not reliably determine the composition of the harvest in SEAK because (1) it does not include fish originating from transboundary rivers (i.e., Taku, Stikine, Alsek rivers); (2) only 1 of its 30 model stocks originates from SEAK and it only represents a small proportion of the natural production of SEAK Chinook salmon; and (3) the model is based on "treaty Chinook" which excludes nearly all of the Southeast Alaska hatchery-produced Chinook salmon harvested in SEAK fisheries. For domestic applications, the preferred way to estimate the composition of the SEAK Chinook salmon harvest is to apply fishery stock composition data from MSA to harvest data. This approach has been successfully applied to the SEAK commercial troll fishery from 1999 through 2014 (Templin et al. 2011; Gilk-Baumer et al. 2013, 2017a, 2017b) and SEAK sport fishery from 2004 through 2015 (Gilk-Baumer et al. *In prep*).
3. Bernard et al. (2014) investigated using genetic analysis in combination with CWTs to estimate terminal run size of Chinook salmon in 2011 from 4 large stock groups that are major contributors to SEAK troll and sport fisheries: *West Coast Vancouver Island*, *Washington Coast*, *North Oregon Coast*, and *Upper Columbia River Falls*. This driver stock method has proven successful for estimating the terminal run size of several of the stocks that are major contributors to the SEAK fishery and has resulted in an ongoing annual effort.

CONCLUSIONS

1. The fine-scale reporting groups that contributed the highest proportion of Chinook salmon harvest to the SEAK troll fisheries in AY 2016 from largest to smallest are the *Interior Columbia Su/F*, *North Oregon Coast*, *West Vancouver*, *South Thompson*, *BC Coast/Haida Gwaii*, *S Southeast Alaska*, and *Washington Coast* reporting groups. Other reporting groups, such as *Andrew* and *Lower Columbia F*, were also major contributors during some of the seasonal fisheries.
2. The reporting groups that contributed the highest proportion of harvest to the SEAK sport fishery in 2016 from largest to smallest are the *West Vancouver*, *Interior Columbia Su/F*, *S Southeast Alaska*, *BC Coast/Haida Gwaii*, *Washington Coast*, *South Thompson*, *Skeena*, and *Andrew* reporting groups.
3. The 7 driver stocks—*SEAK/TBR*, *NCBC*, *South Thompson*, *West Vancouver*, *Washington Coast*, *Interior Columbia Su/F*, and *Oregon Coast* collectively contributed 90% to the regionwide troll harvest and 94% to the season total sport fishery harvest in AY 2016.

4. Stocks from SEAK and the associated transboundary rivers were the largest contributors to the spring troll fishery harvest, particularly in the SI quadrant, and to sport fisheries conducted in SEAK inside waters (Northern Inside, Petersburg-Wrangell, and Ketchikan areas).
5. Troll and sport fisheries conducted in outside waters (NO quadrant and Outside area) harvested a greater variety of stocks including those from British Columbia and the Pacific Northwest than fisheries occurring in inside waters.
6. Summer and fall-run Chinook salmon originating from the Upper Columbia River were the largest contributors overall to the regionwide total troll fishery harvest and the second largest contributors to the sport fishery harvest in AY 2016.

ACKNOWLEDGEMENTS

We thank the following current and former members of the Gene Conservation Laboratory team: Heather Hoyt, Zac Grauvogel, Judy Berger, Erica Chenoweth, Paul Kuriscak, Zach Pechacek, and the many seasonal and borrowed personnel who assisted with extractions. We wish to thank the ADF&G Division of Commercial Fisheries Southeast Alaska port sampling staff: Juneau/Hoonah/Yakutat Port Supervisor Anne Reynolds-Manney, port sampling staff, and Regional Scale Aging lab staff; Petersburg/Wrangell Port Supervisor Jeff Rice and port sampling staff; Ketchikan/Craig Port Supervisor Anna Buettner and port sampling staff; and the Sitka/Pelican/Elfin Cove Port Supervisor Rhea Ehresmann and port sampling staff. We wish to thank the ADF&G Division of Sport Fish Southeast Alaska port sampling staff: Levon Alexander, Katie Ashbaugh, Kirsten Baltz, Nick Bartow, Dan Bennion, John Cooney, April Emmorey, Sharyn Ferrick, Amy Foster, Patrick Fowler, Vera Goudima, Allen Hoffman, Emma Hopkins, Hitsati Hudson, Michael Jaenicke, Emmy Johnson, Jay Kingery, Melissa Kleeman, Bruce Kruger, Adam Lake, Jessica Lombard, Mary Jo Lord-Wild, David Love, Laurinda Marcello, Gabe Melendrez, Mary Meucci, Craig Monaco, Lindsey Noordman, Andrea Pitz, Autumn Redmond, Jeff Swartling, Diana Tersteeg, Jay Van Houten, Hannah Weddle, Madilyn Willard, and Mike Wood. Thanks to Grant Hagerman for input concerning troll management, and to Bob Chadwick concerning sport fishery management. John H. Clark, Chris Habicht, and William Templin provided insightful review and comments.

20	227–240	*Lower Columbia F*	*Other*	*US South*
21	241–246	*Willamette Sp*	*Other*	*US South*
22	247–302	*Columbia Sp*	*Other*	*US South*
23	303–320	*Interior Columbia Su/F*	*Interior Columbia Su/F*	*US South*
24	321–331	*North Oregon Coast*	*Oregon Coast*	*US South*
25	332–339	*Mid Oregon Coast*	*Oregon Coast*	*US South*
26	340–357	*S Oregon/California*	*Other*	*US South*

Note: Population numbers are listed in Appendix A1. Populations were combined into (1) 26 fine-scale reporting groups, (2) 8 driver stock reporting groups including an *Other* group, and (3) 4 broadscale reporting groups.

[a] Driver stocks are aggregate stocks that consistently make up a large proportion (>5%) of all Chinook salmon harvested annually in Southeast Alaska fisheries, and thus are important stocks that help drive catch allocations under the Pacific Salmon Treaty.

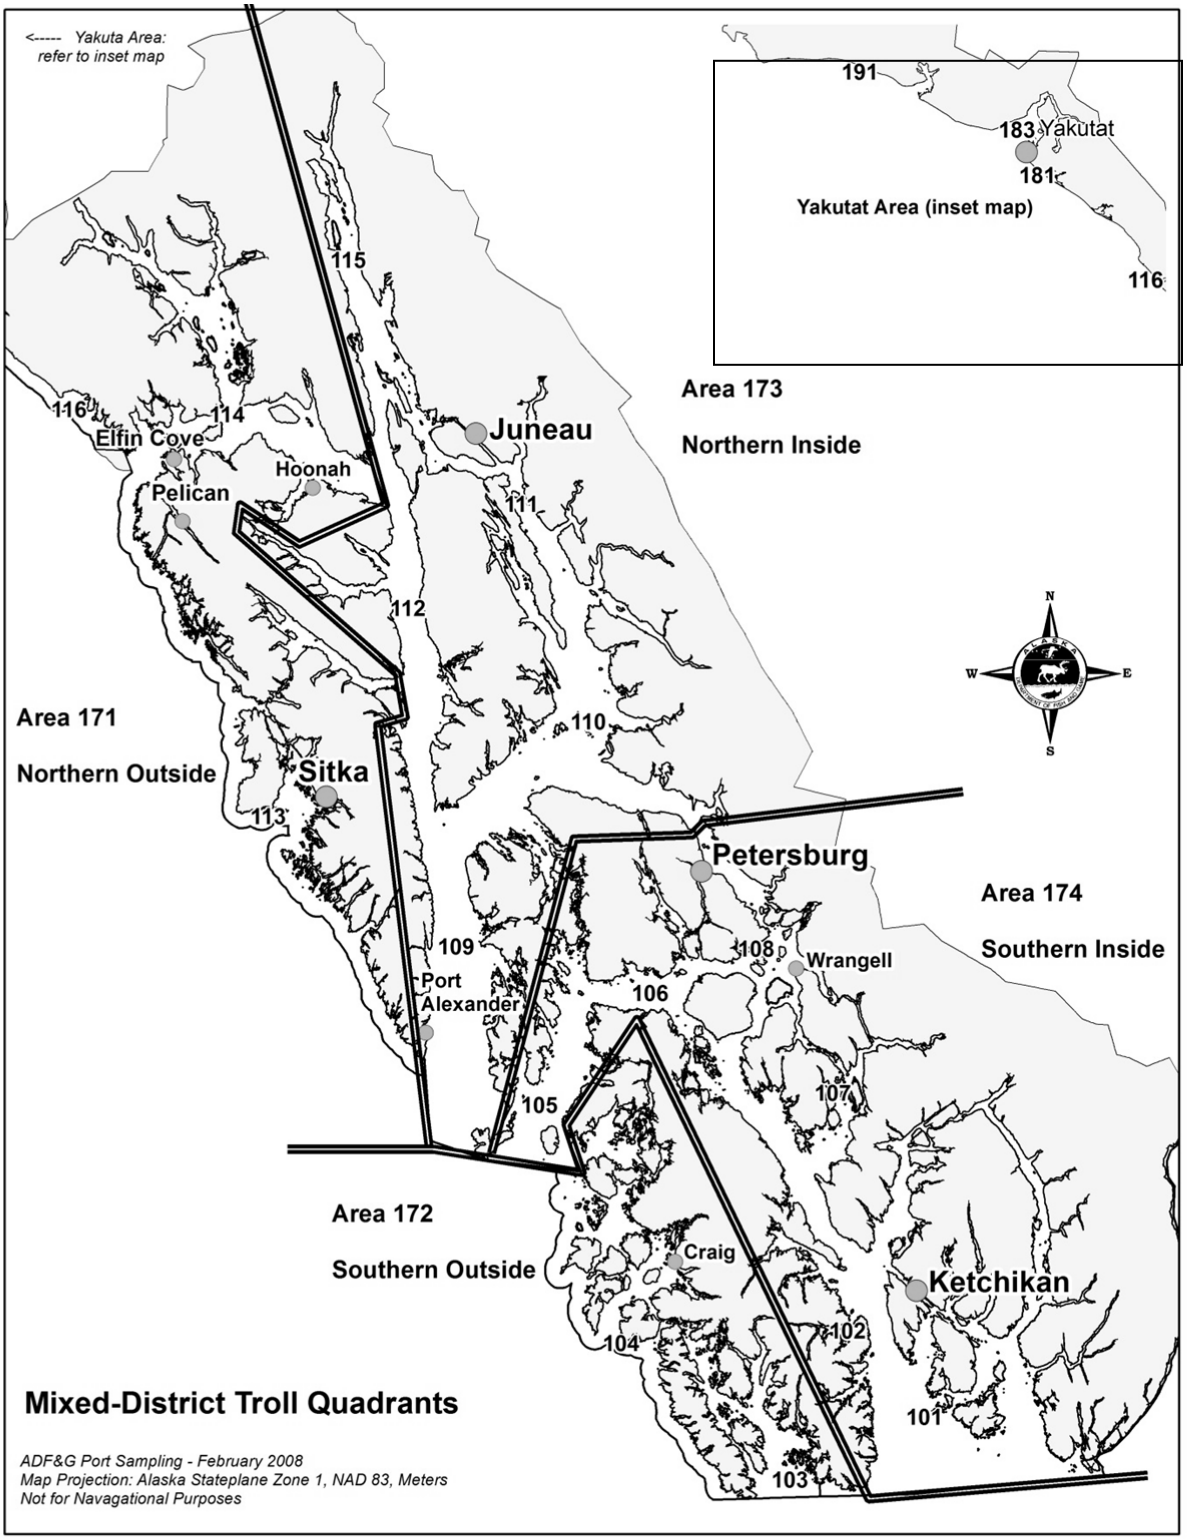

Figure 1.–Location of Southeast Alaska troll fishing quadrants and ports.

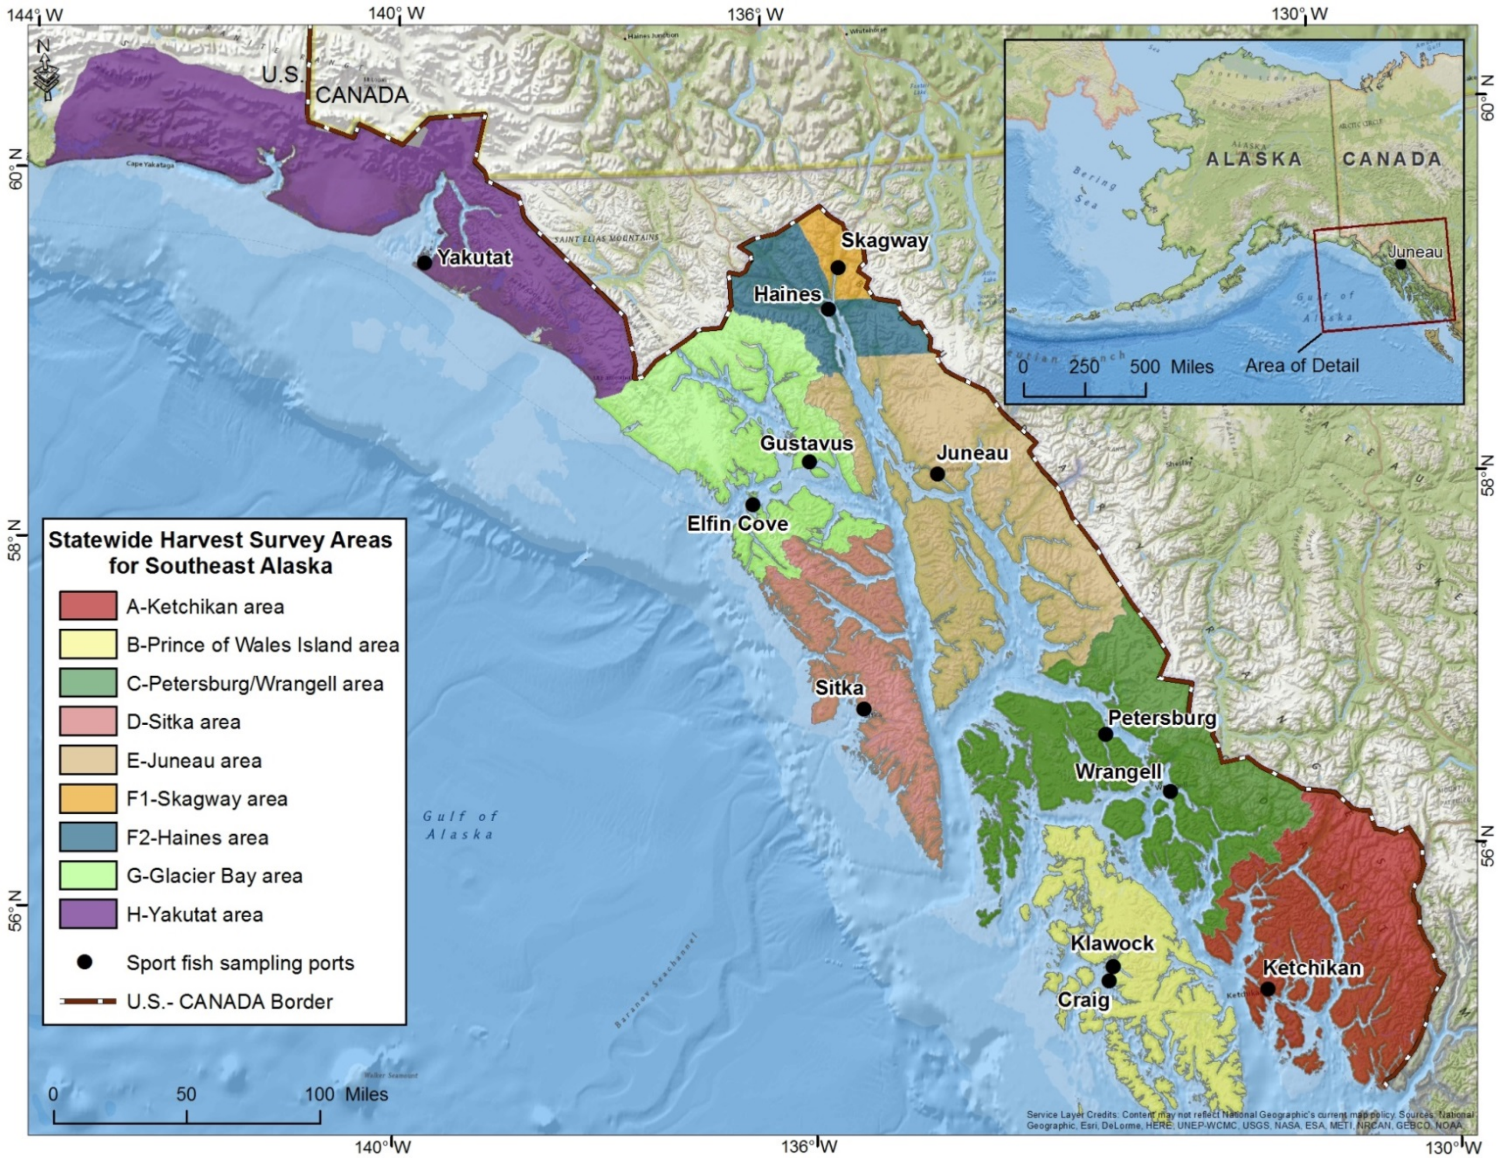

Figure 2.–Location of sport fishing ports in Southeast Alaska.

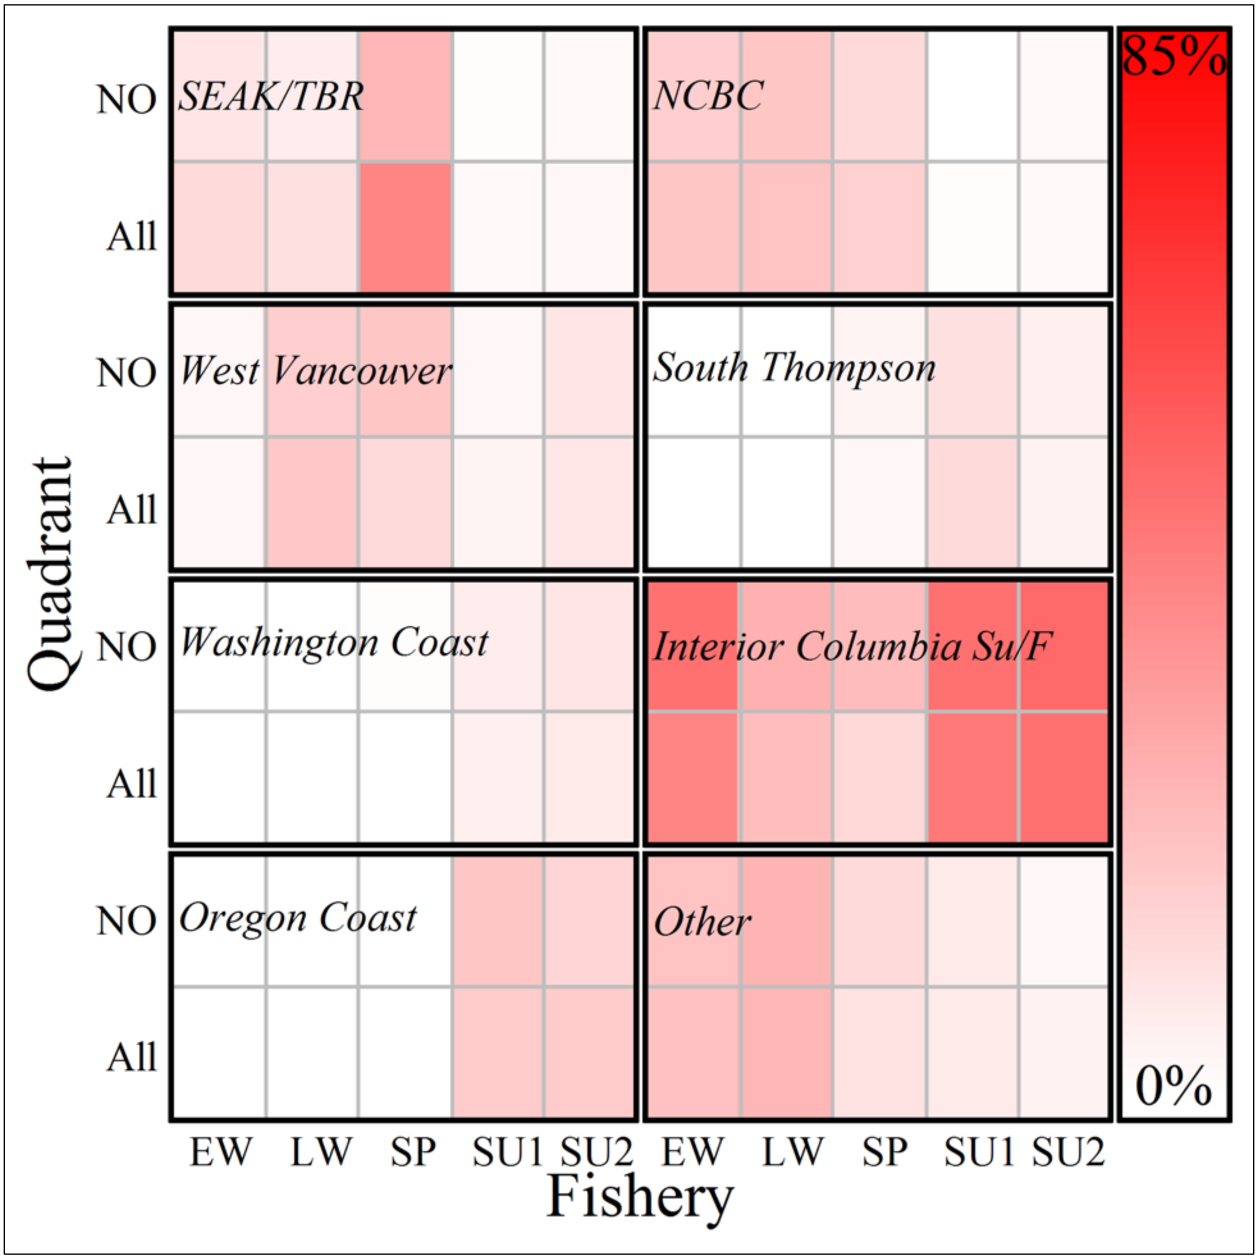

Figure 3.–Heat plot of mean contributions of driver stock reporting groups of Chinook salmon to the troll fishery harvest in Southeast Alaska for the northern quadrant (NO) and the seasonal fishery (All), AY 2016.

Note: Reporting groups are described in Table 1. Driver stocks are aggregate stocks that consistently make up a large proportion (>5%) of all Chinook salmon harvested annually in Southeast Alaska fisheries, and thus are important stocks that help drive catch allocations under the Pacific Salmon Treaty.

Note: Fishery names are abbreviated as follows: Early Winter (EW), Late Winter (LW), Spring (SP), Summer retention period 1 (SU1), and Summer retention period 2 (SU2).

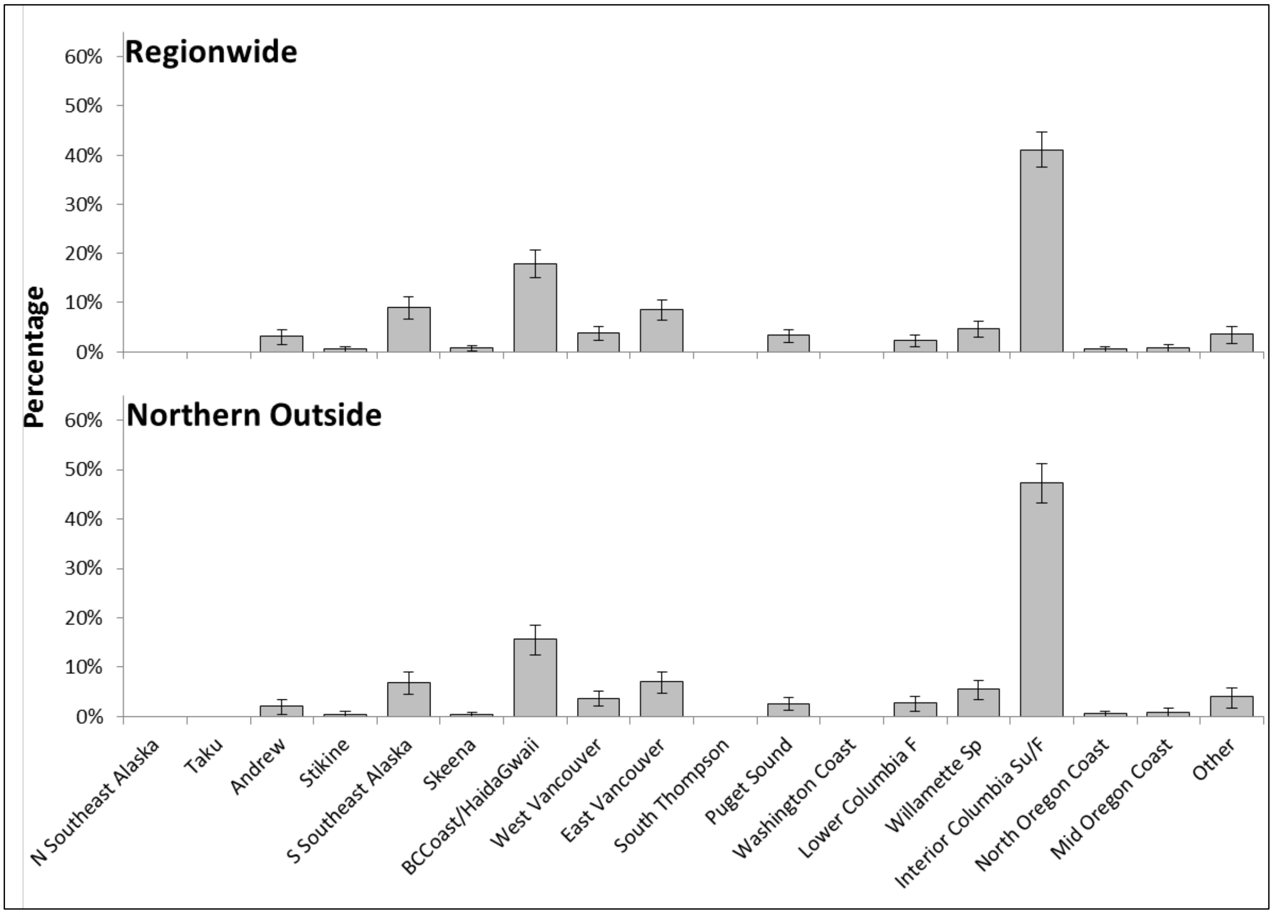

Figure 4.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the regionwide (upper) and Northern Outside quadrant (lower) early winter troll fishery harvest in Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

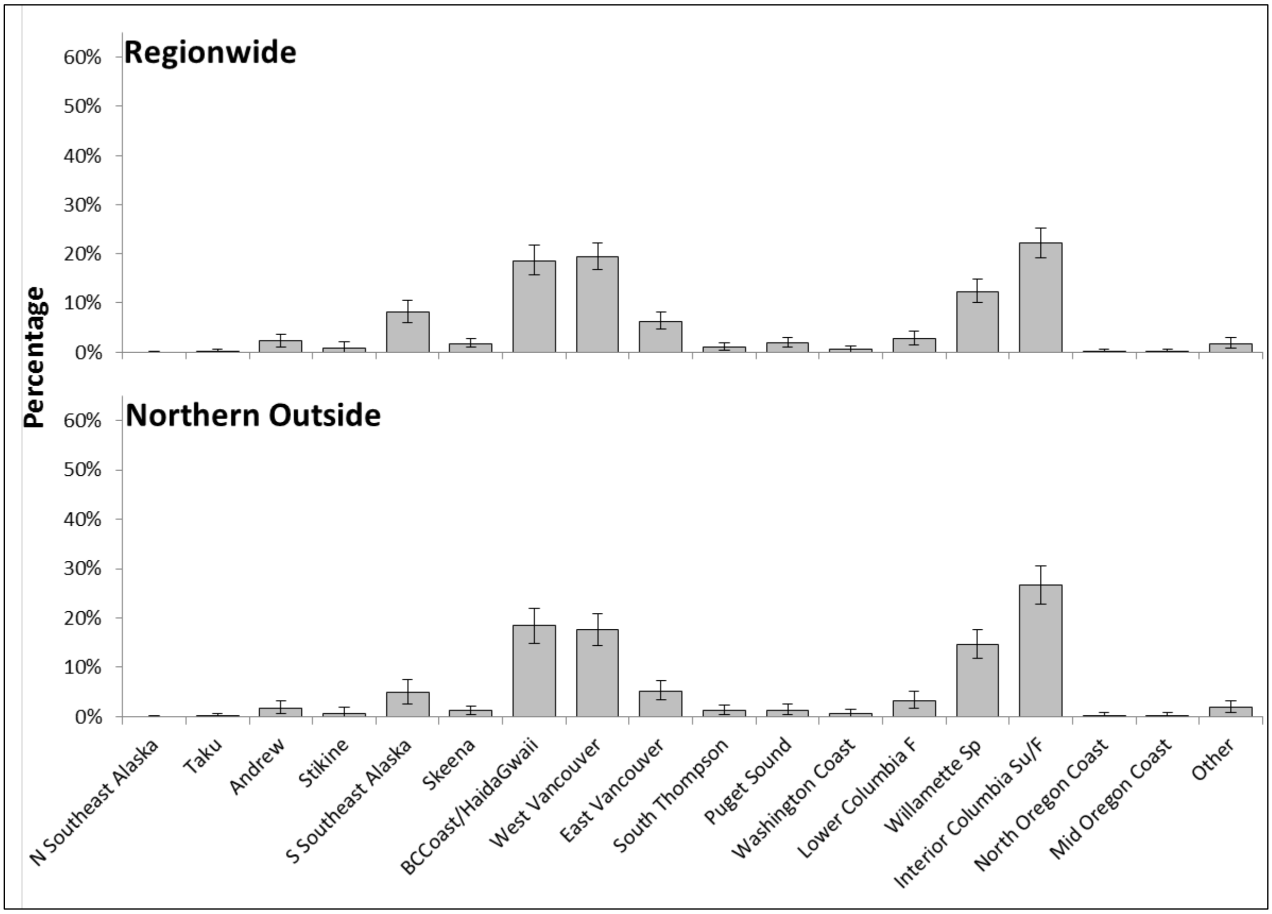

Figure 5.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the regionwide (upper) and Northern Outside quadrant (lower) late winter troll fishery harvest in Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

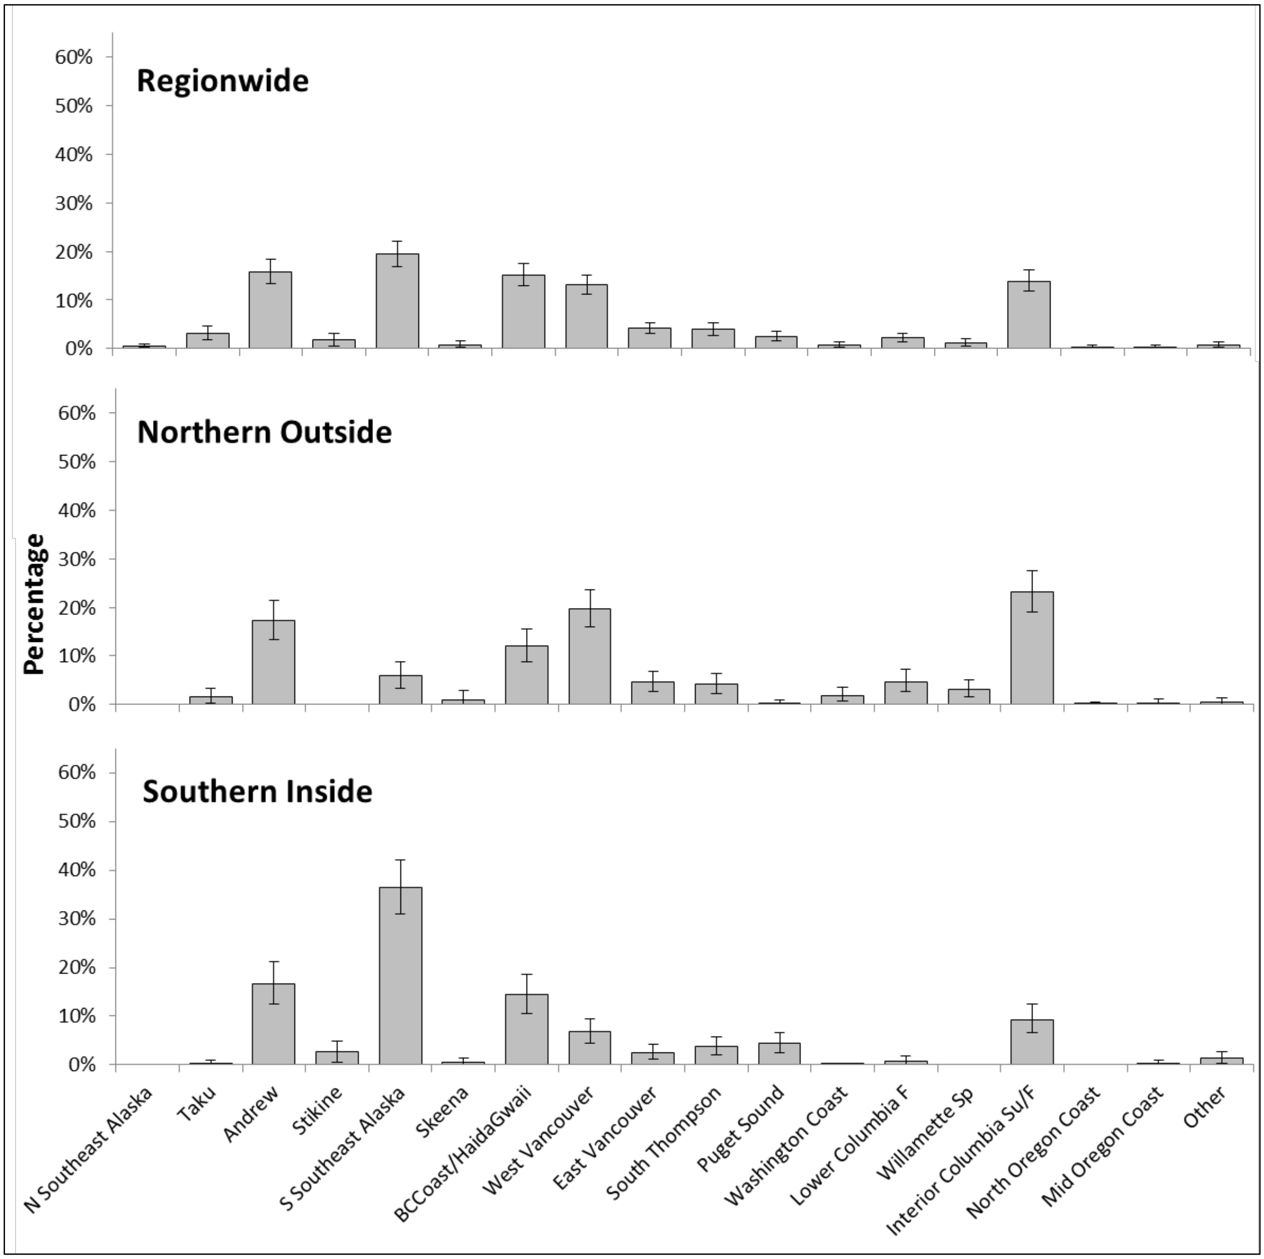

Figure 6.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the spring troll fishery harvest regionwide and in the Northern Outside and Southern Inside quadrants of Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

Note: Inadequate sample sizes precluded estimating stock compositions for Spring Northern Inside medium- and fine-scale reporting groups.

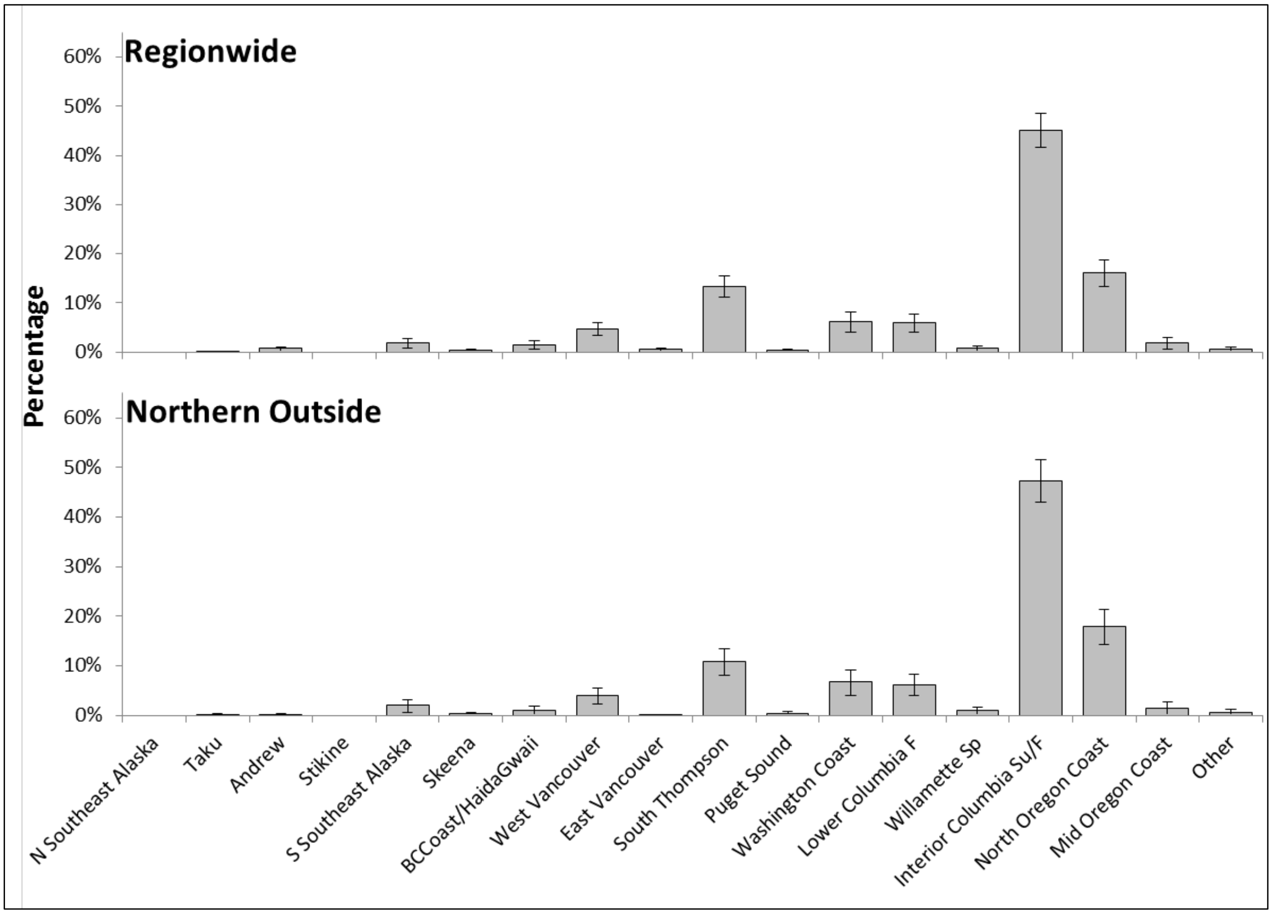

Figure 7.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the regionwide (upper) and Northern Outside quadrant (lower) first retention period of the summer troll fishery harvest in Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

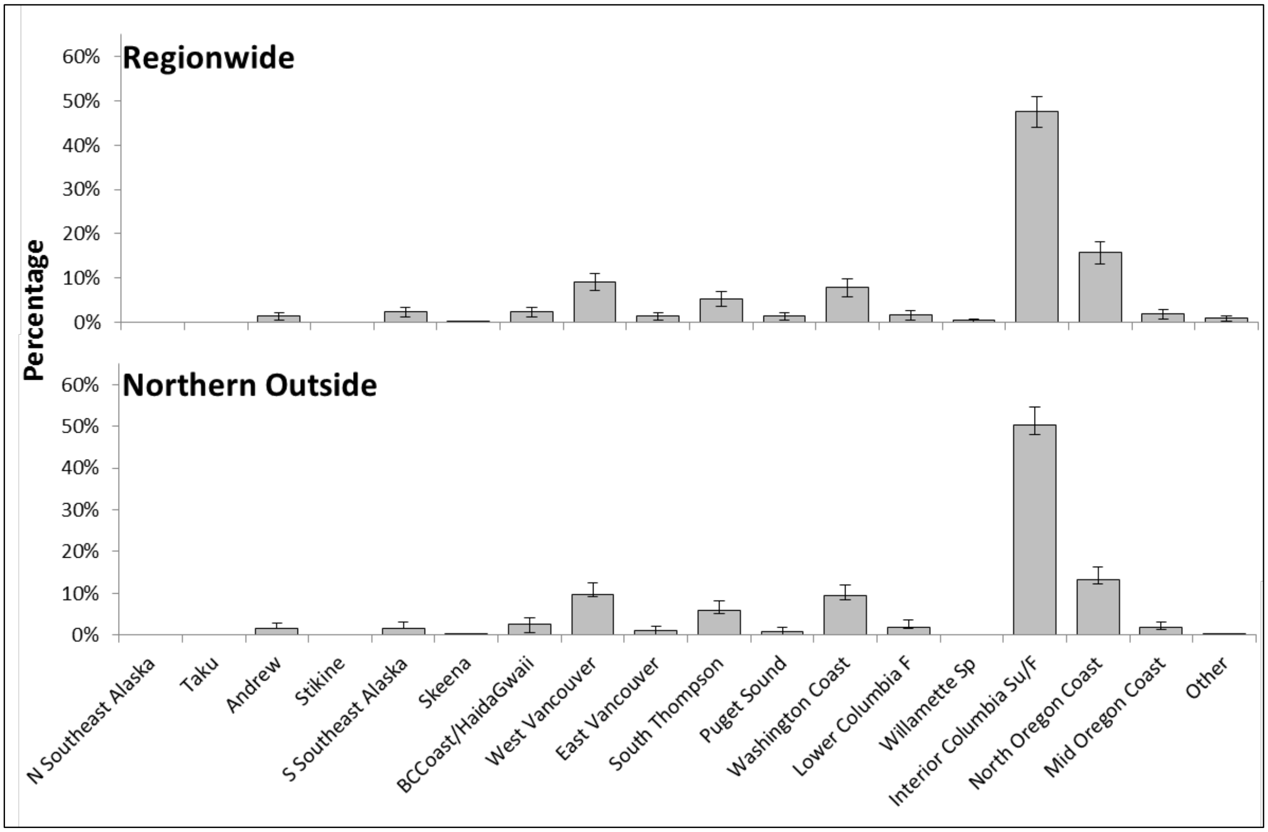

Figure 8.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the regionwide (upper) and Northern Outside quadrant (lower) second retention period of the summer troll fishery harvest in Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

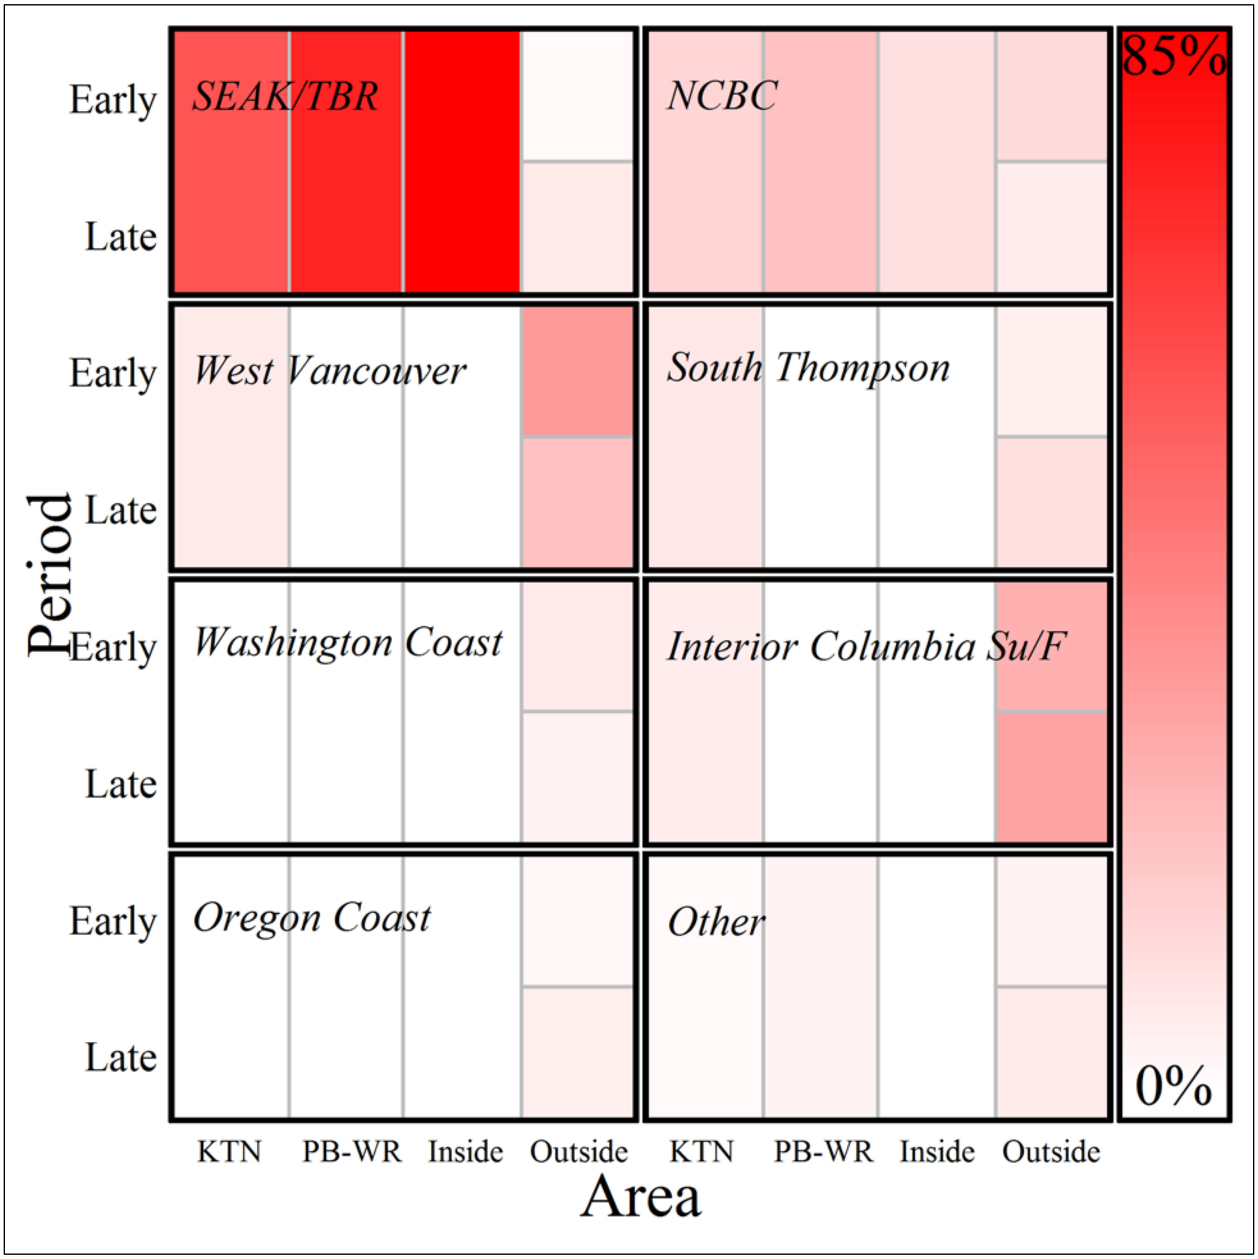

Figure 9.–Heat plot of mean contributions of driver stock reporting groups of Chinook salmon to the sport fishery harvest in Southeast Alaska by area and time period (for the Outside area only), AY 2016.

Note: Reporting groups are described in Table 1. Driver stocks are aggregate stocks that consistently make up a large proportion (>5%) of all Chinook salmon harvested annually in Southeast Alaska fisheries, and thus are important stocks that help drive catch allocations under the Pacific Salmon Treaty.

Note: Fishery names are abbreviated as follows: Ketchikan (KTN) and Petersburg-Wrangell (PB-WR).

Note: Period names for the Outside area are Early (biweeks 9–13) and Late (biweeks 14–18).

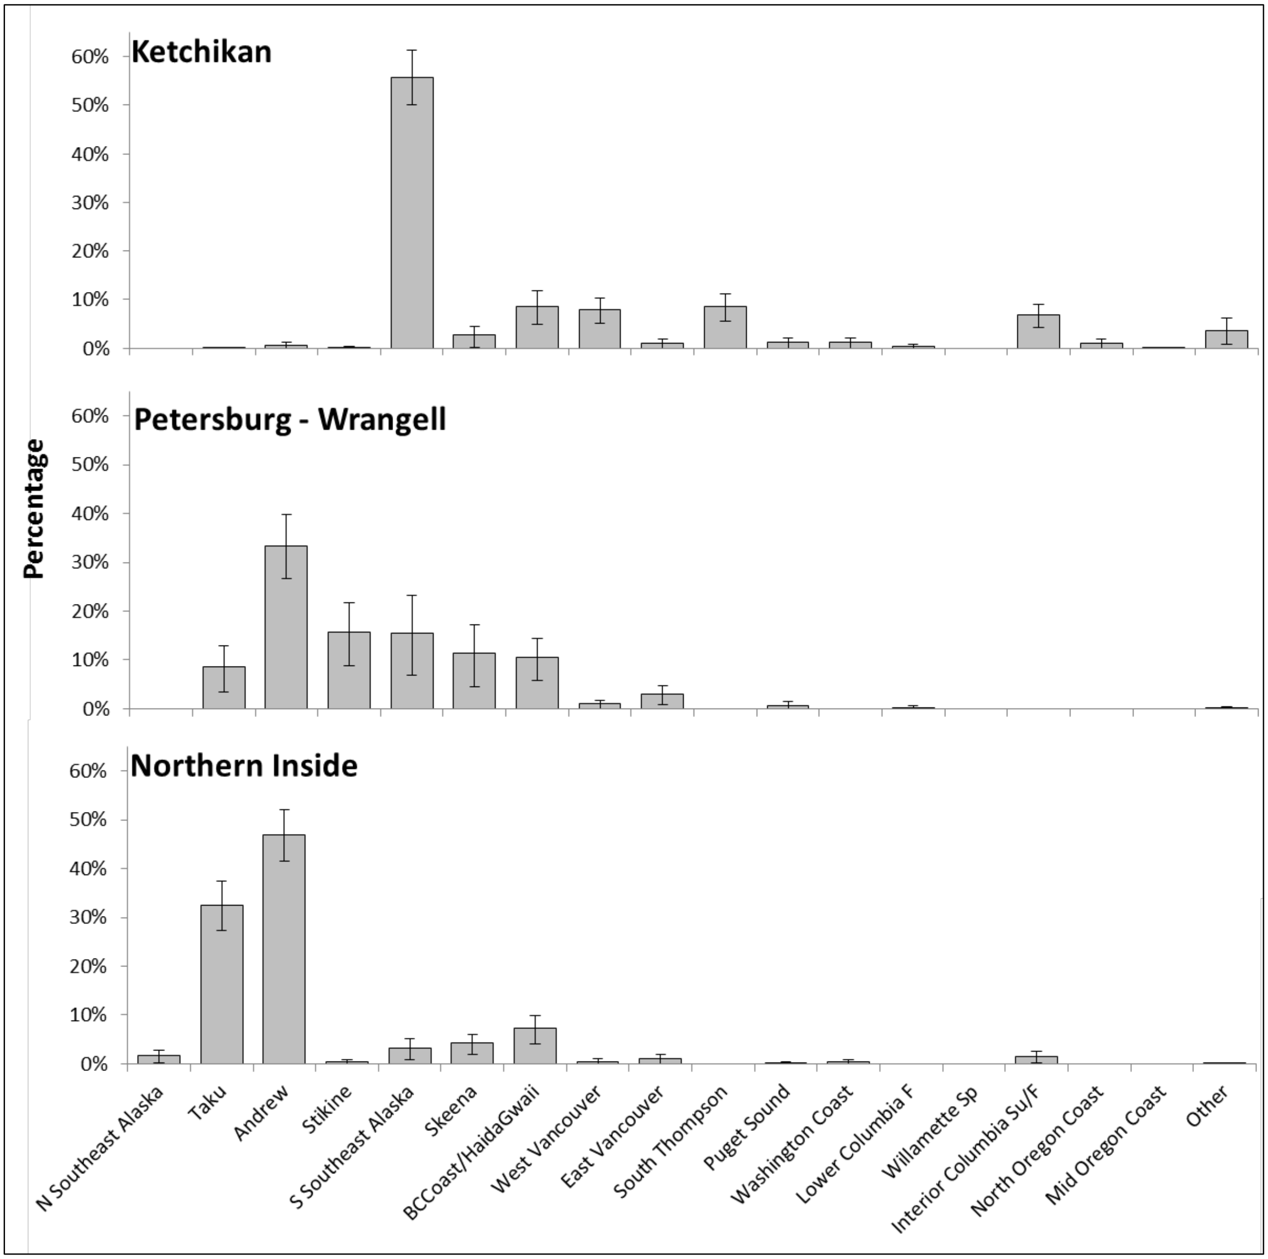

Figure 10.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the Ketchikan, Petersburg-Wrangell, Northern Inside (Juneau, Haines, and Skagway) area sport fishery harvests in Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

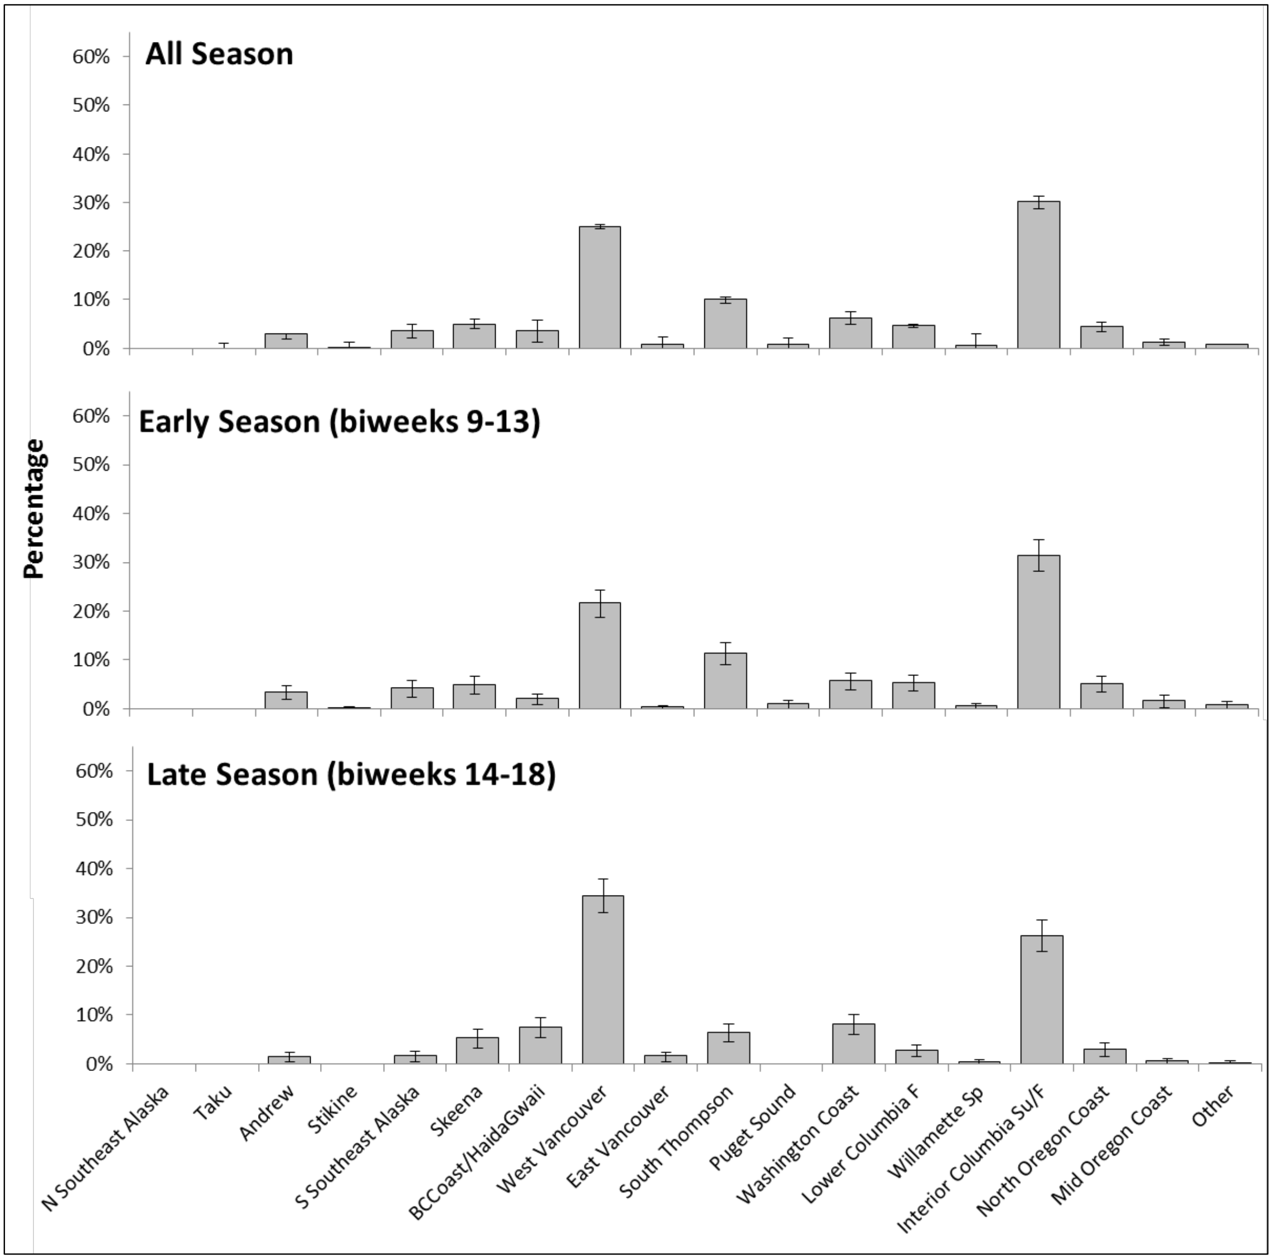

Figure 11.–Estimated contributions and 90% credibility intervals of fine-scale reporting groups of Chinook salmon to the Early Season (biweeks 9–13), Late Season (biweeks 14–18), and total season Outside area sport fishery harvest in Southeast Alaska, AY 2016.

Note: Reporting groups are described in Table 1. The *Other* group consists of those reporting groups that do not contribute more than 5% in any seasonal fisheries. This group includes the *Situk*, *Alsek*, *Nass*, *Fraser*, *Lower Thompson*, *North Thompson*, *West Cascades Sp*, *Columbia Sp*, and *S Oregon/California* reporting groups.

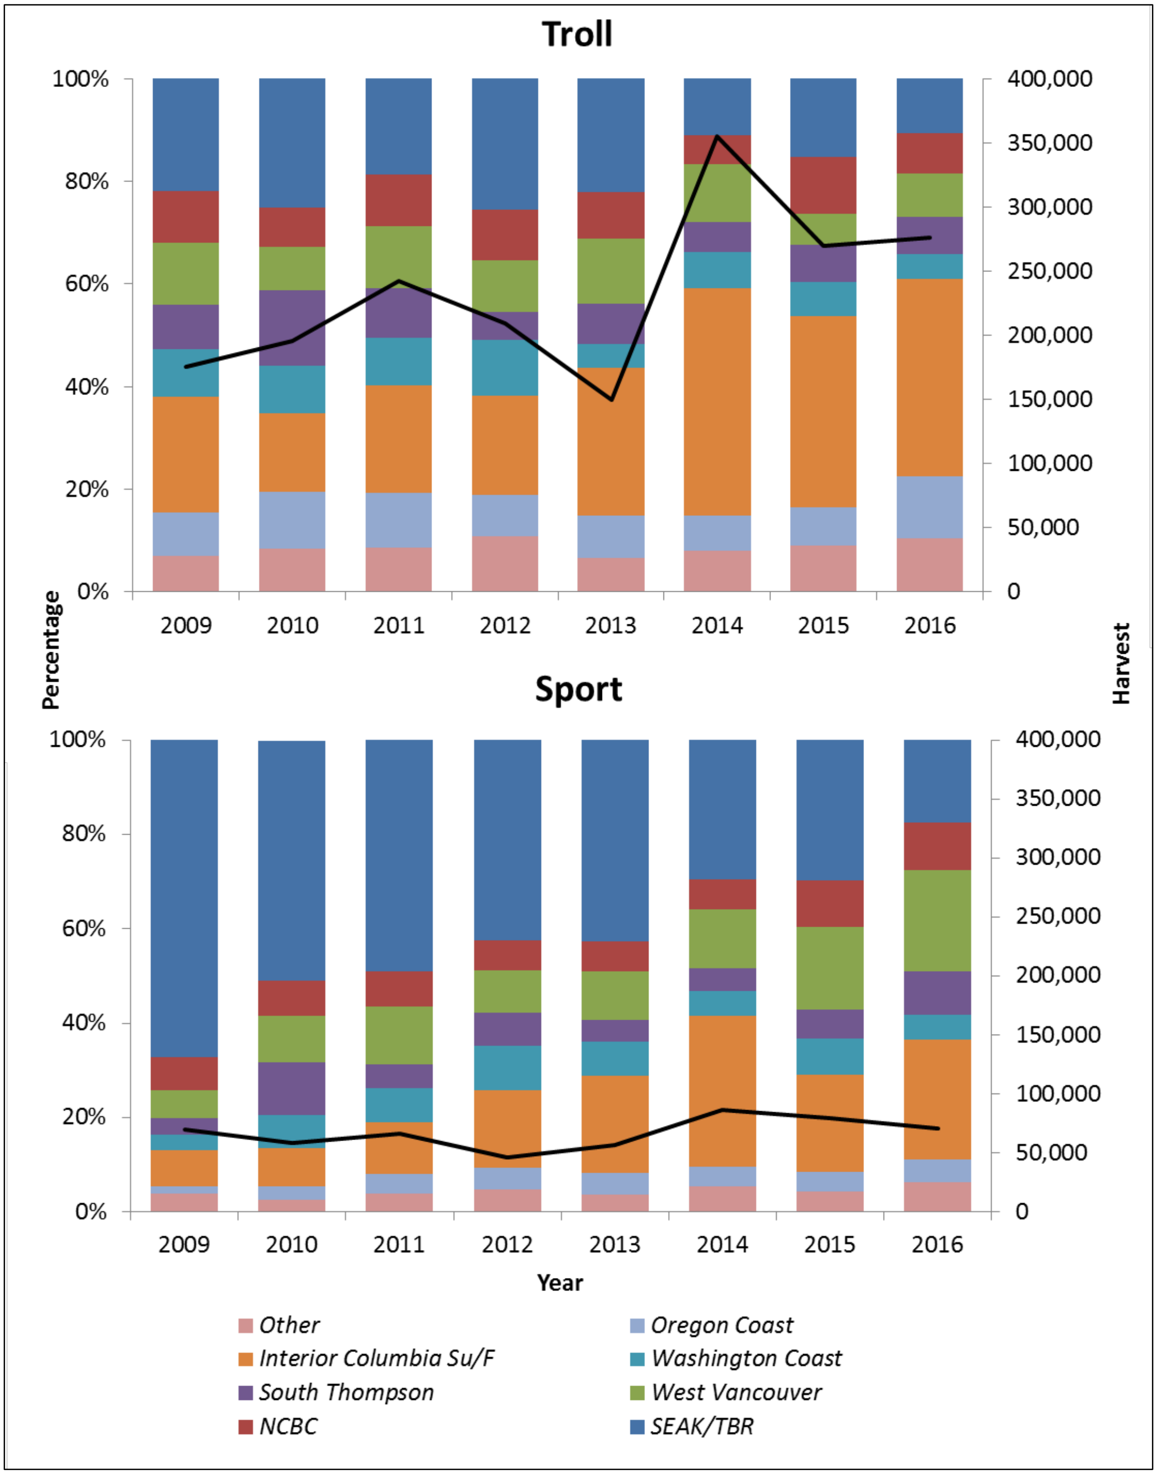

Figure 12.–Mean contributions (stacked bars, scale on the left) and annual harvest (line, scale on the right) of driver stock reporting groups of Chinook salmon to the annual regionwide troll (upper) and sport (lower) fishery harvest in Southeast Alaska, AY 2009–2016.

Note: Reporting groups are described in Table 1. Driver stocks are aggregate stocks that consistently make up a large proportion (>5%) of all Chinook salmon harvested annually in Southeast Alaska fisheries, and thus are important stocks that help drive catch allocations under the Pacific Salmon Treaty.

APPENDIX A: BASELINE POPULATIONS

Appendix A1.–Location and collection details for each population of Chinook salmon included in the coastwide baseline of microsatellite data.

	Fine-scale Reporting Group	Pop No.[a]	Population	N	Run time[b]	Origin[c]	Life Stage	Collection Date
1	*Situk*	1	Situk River	127		W	Adult	1988, 1990, 1991, 1992
2	*Alsek*	2	Blanchard River	349		W	Adult	2000, 2001, 2002, 2003
		3	Goat Creek	62		W	Adult	2007, 2008
		4	Klukshu River	238		W	Adult	1987, 1989, 1990, 1991, 2000, 2001
		5	Takhanne River	196		W	Adult	2000, 2001, 2002, 2003, 2008
3	*N Southeast Alaska*	6	Big Boulder Creek	138		W	Adult	1992, 1995, 2004
		7	Tahini River--Macaulay Hatchery	77		H	Adult	2005
		8	Tahini River	119		W	Adult	1992, 2004
		9	Kelsall River	153		W	Adult	2004
		10	King Salmon River	143		W	Adult	1989, 1990, 1993
4	*Taku*	11	Dudidontu River	233		W	Adult	2002, 2004, 2005, 2006
		12	Kowatua Creek	288		W	Adult	1989, 1990, 2005
		13	Little Tatsamenie River	684		W	Adult	1999, 2005, 2006, 2007
		14	Little Trapper River	74		W	Adult	1999
		15	Upper Nahlin River	132		W	Adult	1989, 1990, 2004
		16	Nakina River	428		W	Adult	1989, 1990, 2004, 2005, 2006, 2007
		17	Tatsatua Creek	171		W	Adult	1989, 1990
5	*Andrew*	18	Andrew Creek	131		W	Adult	1989, 2004
		19	Andrew Creek–Crystal Hatchery	207		H	Adult	2005
		20	Andrew Creek–Macaulay Hatchery	135		H	Adult	2005
		21	Andrew Creek–Medvejie Hatchery	177		H	Adult	2005
6	*Stikine*	22	Christina River	164		W	Adult	2000, 2001, 2002
		23	Craig River	96		W	Adult	2001
		24	Johnny Tashoots Creek	62		W	Adult	2001, 2004, 2005, 2008
		25	Little Tahltan River	126		W	Adult	2001. 2004
		26	Shakes Creek	164		W	Adult	2000, 2001, 2002, 2007
		27	Tahltan River	80		W	Adult	2008
		28	Verrett River	482		W	Adult	2000, 2002, 2003, 2007
7	*S Southeast Alaska*	29	Chickamin River	126		W	Adult	1990, 2003
		30	King Creek	136		W	Adult	2003
		31	Butler Creek	190		W	Adult	2004
		32	Leduc Creek	43		W	Adult	2004
		33	Humpy Creek	124		W	Adult	2003
		34	Chickamin River–Little Port Walter H.	218		H	Adult	1993, 2005
		35	Chickamin River–Whitman Hatchery	193		H	Adult	2005
		36	Clear Creek	134		W	Adult	1989, 2003, 2004
