HDR ALASKA, INC.

TABLE OF CONTENTS

TABLE OF CONTENTS....9-i
LIST OF TABLES....9-iv
LIST OF FIGURES....9-vii
PHOTOGRAPHS....9-xxi
LIST OF APPENDICES....9-xxii
ACRONYMS AND ABBREVIATIONS....9-xxiv
9. WATER QUALITY....9.0-1
9.0. Introduction....9.0-1
9.0.1. Study Objectives....9.0-1
9.0.2. Study Areas....9.0-1
9.0.2.1. Mine Study Area....9.0-1
9.0.2.2. Transportation Corridor Study Area....9.0-1
9.0.3. Types of Sampling and Constituents Analyzed....9.0-1
9.0.4. Methods....9.0-2
9.0.5. Relevance of Each Constituent....9.0-2
9.0.6. Data Reduction....9.0-3
9.0.6.1. Data Qualifiers....9.0-3
9.0.6.2. Comparison of Dissolved and Total Analyses....9.0-4
9.0.6.3. Treatment of Non-Detect Values....9.0-5
9.0.6.4. Treatment of Triplicate Samples....9.0-5
9.0.6.5. Classification of Constituents for Data Interpretation....9.0-5
9.0.6.6. Outlier Analysis....9.0-6
9.0.6.7. Logarithmic Scales....9.0-7
9.0.6.8. Piper Plots....9.0-8
9.0.6.9. Other Data Reduction Methods....9.0-9
9.0.7. Approach to Comparison with Water Quality Criteria....9.0-9
9.0.8. References....9.0-10
9.1. Surface Water—Mine Study Area....9.1-1
9.1.1. Study Objectives....9.1-1
9.1.2. Study Area....9.1-2
9.1.3. Previous Studies....9.1-2
9.1.4. Scope of Work....9.1-3
9.1.4.1. Streams....9.1-4
9.1.4.2. Seeps....9.1-5
9.1.4.3. Lakes and Ponds....9.1-5
9.1.5. Methods....9.1-6
9.1.5.1. Water Quality Stream Sample Location Selection and Nomenclature....9.1-6

9.1.5.2. Seep Sample Location Selection and Nomenclature 9.1-7
9.1.5.3. Water Quality Stream Field Measurement 9.1-8
9.1.5.4. Water Quality Seep Sample Collection 9.1-9
9.1.5.5. Seep Review Methodology 9.1-10
9.1.6. Data Reduction 9.1-11
9.1.7. Outlier Analysis 9.1-12
9.1.8. Streams 9.1-13
9.1.8.1. Results and Discussion: North Fork Koktuli River 9.1-13
9.1.8.2. Results and Discussion: South Fork Koktuli River 9.1-27
9.1.8.3. Results and Discussion: Upper Talarik Creek 9.1-43
9.1.8.4. Results and Discussion: Kaskanak Creek 9.1-58
9.1.8.5. Comparison Across River Systems 9.1-66
9.1.9. Seeps 9.1-68
9.1.9.1. Results and Discussion: North Fork Koktuli Seeps 9.1-68
9.1.9.2. Results and Discussion: South Fork Koktuli Seeps 9.1-77
9.1.9.3. Results and Discussion: Upper Talarik Seeps 9.1-86
9.1.9.4. Regional Evaluation of Seeps Data 9.1-95
9.1.10. Lakes and Ponds 9.1-99
9.1.10.1. Results and Discussion: All Lakes and Ponds Data 9.1-99
9.1.10.2. Results and Discussion: Frying Pan Lake 9.1-104
9.1.10.3. Results and Discussion: Lakes and Ponds Other than Frying Pan Lake 9.1-110
9.1.10.4. Comparison Between Lake and Pond Datasets 9.1-117
9.1.11. Summary 9.1-118
9.1.12. References 9.1-119
9.2. Groundwater—Mine 9.2-1
9.2.1. Introduction 9.2-1
9.2.2. Study Objectives 9.2-1
9.2.3. Scope of Work 9.2-1
9.2.4. Methods 9.2-2
9.2.4.1. Site Selection 9.2-2
9.2.4.2. Well Naming Convention 9.2-2
9.2.4.3. Groundwater Sampling Methods 9.2-3
9.2.4.4. Data Interpretation Methods 9.2-4
9.2.4.5. Data Quality Checks 9.2-5
9.2.5. Results and Discussion 9.2-7
9.2.5.1. Field and Physical Parameters 9.2-7
9.2.5.2. Dissolved Major Ions 9.2-11
9.2.5.3. Nutrients 9.2-18
9.2.5.4. Trace Elements 9.2-19
9.2.5.5. Cyanides 9.2-26
9.2.5.6. Constituent Correlations 9.2-26
9.2.5.7. Temporal Trend Analysis 9.2-27
9.2.5.8. Deep Groundwater Samples 9.2-28
9.2.6. Summary 9.2-29
9.2.7. References 9.2-30

9.3. Surface Water—Transportation Corridor 9.3-1
9.3.1. Introduction 9.3-1
9.3.2. Study Objectives 9.3-1
9.3.3. Study Area 9.3-1
9.3.4. Scope of Work 9.3-1
9.3.5. Methods 9.3-1
9.3.5.1. Site Selection 9.3-1
9.3.5.2. Sampling Procedures 9.3-2
9.3.5.3. Data Analysis 9.3-2
9.3.6. Results and Discussion 9.3-3
9.3.6.1. Field and Physical Parameters 9.3-4
9.3.6.2. Major Ions 9.3-5
9.3.6.3. Nutrients 9.3-7
9.3.6.4. Total and Dissolved Trace Elements 9.3-8
9.3.6.5. Cyanide 9.3-12
9.3.6.6. Organic Compounds 9.3-12
9.3.6.7. Stream Sediment Summary 9.3-12
9.3.7. Summary 9.3-13
9.3.8. References 9.3-13
9.4. Drinking Water Characterization – Transportation Corridor 9.4-1
9.4.1. Introduction 9.4-1
9.4.2. Study Area 9.4-1
9.4.3. Scope of Work 9.4-1
9.4.4. Methods 9.4-1
9.4.4.1. Site Selection 9.4-1
9.4.4.2. Drinking Water Sampling Procedures 9.4-2
9.4.4.3. Analysis 9.4-2
9.4.5. Results and Discussion 9.4-3
9.4.6. Summary 9.4-4
9.4.7. References 9.4-5
9.5. Surface Water—Iliamna Lake 9.5-1
9.5.1. Introduction 9.5-1
9.5.2. Summary of Results and Discussion 9.5-1

LIST OF TABLES

Table 9.0-1, Analytes for Laboratory Determination

Table 9.0-2, Most Stringent Criterion for Major Ions and Minor Ions, Physical Parameters, and Tritium in Water Criteria

Table 9.0-3, Most Stringent Criterion for Trace Metals in Water

Table 9.1-1, Teck Alaska Project MRL and Pebble Project MRL Comparison, Mine Study Area

Table 9.1-2, Period-of-Record Index by Sample Location, Surface Water Program, Mine Study Area

Table 9.1-3, Baseline Surface Water Analytes for Laboratory Determination

Table 9.1-4, Rationale for Selection of Seeps Evaluated for Spatial and Temporal Trends

Table 9.1-5, Surface Water Data Summary for Naturally Occurring Constituents, North Fork Koktuli River

Table 9.1-6, Surface Water Data Summary for Naturally Occurring Constituents, South Fork Koktuli River

Table 9.1-7, Surface Water Data Summary for Naturally Occurring Constituents, Upper Talarik Creek

Table 9.1-8, Surface Water Data Summary for Naturally Occurring Constituents, Kaskanak Creek

Table 9.1-9, Input Values for Preliminary Estimates of Hardness-Dependent Freshwater Aquatic Life Criteria Calculations

Table 9.1-10, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, North Fork Koktuli River

Table 9.1-11, Upstream to Downstream Sample Location Ranks for Spatial Analyses, North Fork Koktuli River

Table 9.1-12, Results of Spatial Regression Analysis of Median Concentrations for Naturally Occurring Constituents in Surface Water, North Fork Koktuli River

Table 9.1-13, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, South Fork Koktuli River

Table 9.1-14, Upstream to Downstream Sample Location Ranks for Spatial Analyses, South Fork Koktuli River

Table 9.1-15, Results of Spatial Regression Analysis of Median Concentrations for Naturally Occurring Constituents in Surface Water, South Fork Koktuli River

Table 9.1-16, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Upper Talarik Creek

Table 9.1-17, Upstream to Downstream Sample Location Ranks for Spatial Analyses, Upper Talarik Creek

Table 9.1-18, Results of Spatial Regression Analysis of Median Concentrations for Naturally Occurring Constituents in Surface Water, Upper Talarik Creek

Table 9.1-19, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Kaskanak Creek

Table 9.1-20, Differences in Naturally Occurring Constituent Concentrations in Surface Water Across River Systems, Mine Study Area

Table 9.1-21, Differences in Naturally Occurring Constituent Concentrations in Surface Water Between Paired River Systems, Mine Study Area

Table 9.1-22, Surface Water Data Summary for Naturally Occurring Constituents, Seeps Across the Mine Study Area

Table 9.1-23, Surface Water Data Summary for Naturally Occurring Constituents, Seeps in the North Fork Koktuli River Drainage

Table 9.1-24, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Seeps, North Fork Koktuli River Drainage

Table 9.1-25, Surface Water Data Summary for Naturally Occurring Constituents, Seeps in the South Fork Koktuli River Drainage

Table 9.1-26, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Seeps, South Fork Koktuli River Drainage

Table 9.1-27, Surface Water Data Summary for Naturally Occurring Constituents, Seeps in the Upper Talarik Creek Drainage

Table 9.1-28, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Seeps, Upper Talarik Creek Drainage

Table 9.1-29, Differences in Naturally Occurring Constituent Concentrations in Seeps Between Paired River Systems, Mine Study Area

Table 9.1-30, Differences in Naturally Occurring Constituent Concentrations in Seeps Based on Discharge Velocities in Different Drainages, Mine Study Area

Table 9.1-31, Surface Water Data Summary for Naturally Occurring Constituents, All Lakes in the Study Area

Table 9.1-32, Surface Water Data Summary for Naturally Occurring Constituents, Frying Pan Lake

Table 9.1-33, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Frying Pan Lake

Table 9.1-34, Surface Water Data Summary for Naturally Occurring Constituents, Lakes in the Study Area Other than Frying Pan Lake

Table 9.1-35, Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Lakes in the Mine Study Area Other than Frying Pan Lake

Table 9.1-36, Differences in Naturally Occurring Constituent Concentrations in Surface Water Between Frying Pan Lake and Other Lakes, Mine Study Area

Table 9.2-1, Screens Completed at Each Groundwater Monitoring Location, Mine Study Area, 2004-2008

Table 9.2-2, Frequency of Detection and Method Detection Limit by Parameter for Groundwater Samples, Mine Study Area, 2004-2008

Table 9.2-3, Groundwater Monitoring Wells with Distinctive Water Chemistry, Mine Study Area, 2004-2008

Table 9.2-4, Sampled Intervals in Deep Borehole 8417, Mine Study Area, 2004-2008

Table 9.3-1, Surface Water Quality Sample Stations – Transportation-corridor, Bristol Bay Drainages Study Area (2004-2005)

Table 9.3-2, Surface Water Data Summary for Naturally Occurring Constituents, Eastern Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-3, Surface Water Data Summary for Naturally Occurring Constituents, Western Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-4, Comparison of Human Health Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Eastern Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-5, Comparison of Human Health Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Western Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-6, Comparison of Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Eastern Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-7, Comparison of Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Western Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-8, Identification of Surface Water Samples Exceeding Human Health Water Quality Criteria, Eastern Transportation-corridor, Bristol Bay Drainages (2004-2005)

Table 9.3-9, Identification of Surface Water Samples Exceeding Human Health Water Quality Criteria, Western Transportation-corridor, Bristol Bay Drainages (2004-2005)

9. WATER QUALITY

9.0. Introduction

9.0.1. Study Objectives

The common objectives of the surface water quality and groundwater quality sampling programs were as follows:

- Collect baseline data to provide scientific documentation of the naturally occurring constituents (NOCs), their concentrations, and their variability in surface water and groundwater.
- Assemble a database of site water chemistry.
- Interpret the data.

9.0.2. Study Areas

9.0.2.1. Mine Study Area

The mine study area encompasses 392 square miles, and is part of the Nushagak and Kvichak watersheds. It is drained by the North Fork Koktuli River, South Fork Koktuli River, Upper Talarik Creek and Kaskanak Creek (Figure 9.0-1). The deposit area, located roughly in the middle of the mine study area, is at an elevation of about 1,150 feet. This location is approximately two miles north of a lake locally named Frying Pan Lake (elevation 943 feet) and is in the headwaters of both the Koktuli River and Upper Talarik Creek.

The Koktuli River drains to the Nushagak River and then to Bristol Bay. Upper Talarik Creek drains to Iliamna Lake, which in turn drains to the Kvichak River. Kaskanak Creek drains to the Kvichak River south of Iliamna Lake.

9.0.2.2. Transportation Corridor Study Area

The transportation-corridor, Bristol Bay drainages study area is generally bounded by the Newhalen River in the west, the northern shore of Iliamna Lake in the south, the outlet of Lake Clark and the base of Roadhouse Mountain in the north, and the drainage divide between Bristol Bay and Cook Inlet drainages in the east. The study area is more specifically defined by the location of the sampling stations as depicted in Figure 9.0-2.

9.0.3. Types of Sampling and Constituents Analyzed

Surface water and groundwater quality samples were collected in the area of the Pebble Deposit and along the transportation corridor. The inorganic constituents that were analyzed were common to both types of samples, including field and physical parameters, dissolved major ions, nutrients, trace elements, and cyanides (Table 9.0-1). Some surface water samples were also analyzed for petroleum hydrocarbons

(gasoline-range organics, diesel-range organics, and residual-range organics), volatile organic compounds, semi-volatile organic compounds, polychlorinated biphenyls (PCBs), and pesticides.

9.0.4. Methods

The methods used for site selection, sampling, and data interpretation are described in the respective surface water or groundwater sub-section.

9.0.5. Relevance of Each Constituent

Each constituent that was measured in the water quality program had its own relevance to the interpretation of the water quality. The following paragraphs describe each of these parameters:

- Specific Conductance: Specific conductance is a measure of the ability of water to conduct an electric current, and is determined by the type and concentration of ions in solution. It is a readily measured property that is generally proportional to the total dissolved solids in the water.
- pH: The pH of water is a measure of its hydrogen-ion activity and can theoretically range from 0 (very acidic) to 14 (very alkaline) standard units. The typical pH range of natural water is about 5 to 8, where a pH of 7 indicates water that is perfectly neutral.
- Water Temperature: Water temperature is one of the most important factors in the health of a stream ecosystem and determines the upper limit of dissolved oxygen when at equilibrium with the atmosphere. It also controls the metabolic rates of fish and their rates of growth.
- Dissolved Oxygen: The dissolved oxygen concentration in a stream is controlled by several factors, including water temperature, air temperature and pressure, hydraulic characteristics of the stream, photosynthetic or respiratory activity of stream biota, and the quantity of organic matter present. Dissolved oxygen is a constituent that affects the health of fish.
- Alkalinity: Alkalinity is a measure of the capacity of the dissolved ions to neutralize acid. It is formally defined as the sum total of components in the water that can buffer pH of the water above 4.5, and it is expressed as equivalent milligrams per liter (mg/L) of calcium carbonate ($CaCO_3$). In most natural waters, alkalinity occurs primarily as bicarbonate and carbonate (Hem, 1985), which are ions formed when carbonate rocks weather. Given the typical range of pH values in natural waters, most of the alkalinity can be assigned entirely too dissolved bicarbonate (Hem, 1985). Alkalinity is considered to be a measure of the buffering capacity of the water, and since pH has a direct effect on organisms as well as an indirect effect on the toxicity of some pollutants in the water, it is important to consider during water quality evaluations.
- Hardness: Water hardness is the sum of the concentrations of calcium and magnesium, and is expressed as equivalent mg/L $CaCO_3$. The presence of calcium and/or magnesium is known to moderate the toxicity of some metals; in particular, the toxicity of cadmium, chromium III, copper, lead, nickel, silver, and zinc decrease as water hardness increases.
- Nutrients: A nutrient is an element or compound essential for animal and plant growth, such as nitrogen and phosphorus. Nitrogen is an important water quality constituent, partly because it is an important component of the protoplasm of aquatic biota. In aquatic ecosystems, nitrogen commonly occurs in three ionic forms and one neutral form: nitrate (NO_3^+), nitrite (NO_2^-), ammonium (NH_4^+), and ammonia (NH_3). Nitrate and nitrite are oxidized forms of nitrogen (N)

that together normally constitute most of the dissolved nitrogen in well-aerated streams. For this study, ammonia and ammonium were reported together as total ammonia.

- Phosphorus: Phosphorus is an essential element in the growth of plants and animals. It occurs as organically bound phosphorus or as phosphate. High concentrations of phosphorus in water are not considered to be toxic to human or aquatic life. However, the presence of phosphorus can stimulate the growth of algae in lakes and streams.
- Trace Elements: Trace elements are essential for health in all aquatic organisms in trace amounts. However, high concentrations of trace elements in surface waters can also be related to chronic or acute toxicity. The trace elements aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, tellurium, vanadium, and zinc all have maximum water quality criteria based on toxicity. The toxicity of an element depends on whether it is being evaluated in the context of human health or aquatic life.
- Dissolved Organic Carbon (DOC): DOC is a food source for micro-organisms and the aquatic food web, and it can affect the acid-base chemistry of low-alkalinity waters. DOC also forms strong complexes with trace metals, which affects their bioavailability and mobility. This characteristic has applications to the biotic ligand model for assessing toxicity.

9.0.6. Data Reduction

9.0.6.1. Data Qualifiers

As part of the laboratory analysis for the water samples, data qualifier codes were assigned to some results as follows:

- U: The constituent was not detected above the level of the method reporting limit (MRL). Detections below this limit were attributed to associated blank contamination.
- UJ: The parameter was analyzed but was not detected above the level of the MRL. The MRL is approximate and may be inaccurate or imprecise.
- J: The result was an estimated quantity. The associated numerical value is the approximate concentration of the parameter in the sample.
- J+: The result was an estimated quantity and may be biased high.
- J-: The result was an estimated quantity and may be biased low.
- R: The sample results were rejected due to deficiencies in meeting quality control (QC) criteria. The constituent may or may not be present in the sample.

A total of 4,438 analyses were R-qualified (rejected) out of a total of 274,394 analyses (2 percent). The breakdown of these R-flagged results is as follows:

- Groundwater (Deposit Area): 334 analyses were rejected out 42,185 for the groundwater analyses (1 percent).

- Surface Water (Deposit Area): 3,675 analyses were rejected out 171,502 for surface water in the deposit study area (2 percent).
- Community Well Sampling (Transportation Corridor): 28 analyses were rejected out of 1,502 (2 percent).
- Surface Water (Transportation Corridor): 242 analyses were rejected out of 12,937 (2 percent).

This count includes only analyses of primary samples. The results that were R-qualified during data validation were excluded from the data sets for data analysis and interpretation. The majority of these rejected analyses were dissolved-constituents data where the dissolved concentration was unacceptably higher than the total concentration (discussed in the next sub-section).

9.0.6.2. Comparison of Dissolved and Total Analyses

The project laboratory compared the results of dissolved and total analyses to identify those samples where the concentration of a dissolved metal was greater than the total metal. Where the dissolved concentration was greater than total, the results were evaluated against criteria presented in the quality assurance project plan (QAPP; Appendix G of this environmental baseline document [EBD]). The dissolved concentration was considered valid relative to the total concentration if one of the following criteria was met:

- For dissolved and total results that were both greater than five times the MRL: valid if relative percent difference (RPD) was less than or equal to 20 percent.
- For total metals results that were less than or equal to five times the MRL: valid if absolute value of the difference between the results was less than or equal to the MRL. If the total metals result was not detected at the method detection limit (MDL), the value of the MDL was used for the comparison.
- Valid if total and dissolved results were both below the MRL. (In this case, the results were treated as one-half the MRL in the database).

If more than 30 percent of the results for trace elements did not meet these criteria, then the total and dissolved fractions were reanalyzed if sufficient sample volume was available. The details of this evaluation and the corrective actions that were implemented are described fully in Appendix A, Analytical Data Quality Assurance/Quality Control, of this EBD.

Most analyzed concentrations of dissolved metals and trace elements were less than or equal to the total concentrations within analytical precision. Only nickel and zinc out of 27 metals had a relatively low number of dissolved analysis within the acceptable range: 56% and 76%, respectively (Appendix A, Analytical Data Quality Assurance/Quality Control). Four other metals (barium, cobalt, copper and lead) out of 27 had 80-90% of dissolved analyses within the acceptable range and the other 21 metals had over 90% within the acceptable range. Therefore, the majority of analyses met the 90% completeness criterion for dissolved analyses relative to total analyses. Leaching of trace levels of metals in the water-sample filters were the most likely cause of dissolved analyses that did not meet the 90% completeness criterion.

9.0.6.3. Treatment of Non-Detect Values

Non-detect results were included in statistical summaries (e.g. mean, median, standard deviation, coefficient of variation) and regressions as one-half the MDL, and results flagged with a "U" or "UJ" qualifier were included as one-half the MRL. For the Kruskal-Wallis and Mann Whitney statistical tests, which were used to distinguish differences in surface-water concentrations between watersheds, only detected concentrations and J-qualified results were included to avoid skewing the datasets based on multiple non-detect values.

9.0.6.4. Treatment of Triplicate Samples

Samples were collected in triplicate at 10 percent of the sample stations as a quality assurance/quality control (QA/QC) measure. Only the primary samples were used for data analysis. Triplicate sample data were used to evaluate the precision of the analytical results. These data were also used to help identify outliers.

9.0.6.5. Classification of Constituents for Data Interpretation

For the purpose of interpreting the data, the constituents were divided into several groups as follows:

- Field and physical parameters (total dissolved solids, pH, dissolved oxygen, temperature, specific conductance, turbidity, total suspended solids, oxidation reduction potential) to give a broad overview of the water quality characteristics.
- Major ions (calcium, magnesium, sodium, potassium, alkalinity, sulfate, chloride, fluoride, and hardness) to characterize the constituents that comprise the majority of dissolved solids in the samples.
- Nutrients (total ammonia, nitrate+nitrite, phosphorous, total orthophosphate) to characterize the constituents that can cause eutrophication of water bodies.
- Total and dissolved trace elements (aluminum, antimony, arsenic, barium, cadmium, copper, iron, lead, manganese, mercury, molybdenum, nickel, and zinc) to characterize the constituents that are most commonly associated with toxicity.
- Specific organics (petroleum hydrocarbons (gasoline range organics [GRO], diesel range organics [DRO], and residual range organics [RRO]), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and pesticides to document any naturally occurring or pre-existing concentrations of these compounds.
- Dissolved organic carbon because of its relevance to bioavailability and toxicity assessments.

Eleven trace elements (aluminum, arsenic, barium, iron, cadmium, copper, lead, manganese, molybdenum, nickel, zinc) were selected for the surface water samples for interpretation out of the 19 trace elements analyzed based on their relative toxicity and importance to maintaining aquatic communities, and on their frequency of detection in the water samples. An additional eight parameters (antimony, beryllium, chromium, mercury, selenium, silver, thallium, vanadium) were interpreted for the groundwater samples.

9.0.6.6. Outlier Analysis

Outliers are points in a data set that represent a rare event, belong to a different population (contamination, disequilibrium), or indicate an analysis error. As one of the QA/QC measures prior to data analysis and interpretation, some of the data points were identified as outliers and removed from the data set because they were considered to be errors or did not appear to represent the ambient water quality. The details of the outlier analysis are documented in Appendix 9.1D, Appendix 9.2C, Appendix 9.3A, and Appendix 9.4A for the respective sub-sections of the water quality study.

Outliers were evaluated by visually inspecting a time series plot for each parameter-station combination. Duplicate (DU) and triplicate (QA) samples were plotted with a distinct symbol to distinguish them from the primary analyses. Non-detects were plotted with a different color to distinguish them from actual results. Non-detects and U- and UJ-flagged data were plotted on the time series at half the MDL and MRL respectively. To help with this evaluation, the statistical normal distribution function was used to determine the 98 percent confidence interval of each parameter-station combination. One percent of the data were statistically lower than the lower limit and one percent of the data were statistically higher than the upper limit. Some parameter-station combinations had an outlier that was much higher than all other data, which resulted in a very wide confidence interval relative to most of the data. This wide confidence interval sometimes included other high concentrations in the data set. In these select cases, the extreme value was removed from the data set and the confidence interval was recalculated, resulting in a smaller confidence interval. These limits statistically included 98 percent of all data and were plotted on the time series as horizontal lines for reference. The average concentration and the upper and lower limits of the 98 percent confidence interval were documented in Appendix 9.1D, Appendix 9.2C, Appendix 9.3A, and Appendix 9.4A. These confidence limits were used in conjunction with professional judgment to identify outliers. The confidence test could not be used without professional judgment because the data sets were often not normally distributed and because the frequency of detection was commonly less than 50 percent for trace metals. For the groundwater samples, non-normal behavior was often due to concentrations that trended downward early in the period of record and stabilized later in the period of record. This behavior represented equilibration of the well chemistry to ambient groundwater conditions, a process that was observed to sometimes take more than a year. Therefore, all data were visually inspected in the time series plots and professional judgment was used to identify outliers. Outliers were labeled as “X+” on the time series plots.

The criteria for flagging outliers in the groundwater samples were somewhat different than the criteria used for surface water samples. For groundwater samples, concentration trends early in the sampling record indicated that the well chemistry was equilibrating with the ambient groundwater quality over time. Therefore, some of the samples from the first year of sampling were flagged as outliers because they did not represent actual groundwater quality. The points flagged as outliers for this reason included some results inside the confidence interval and some results outside the confidence interval. Also, groundwater chemistry in a natural system such as the Pebble study area was expected to be relatively stable. Therefore, isolated samples that had much higher concentrations than otherwise observed were flagged as outliers.

For surface water samples, no trends early in the sampling record were observed so outliers were not flagged on this basis as they were in groundwater. Similarly, surface water chemistry was expected to

have high variability corresponding with seasonal flow rates and temperature, and other environmental influences. Therefore, no outliers were flagged for having high or low concentrations.

Because non-detects were included in the data analysis at half the MDL, a process was also developed for both surface water and groundwater samples for flagging outliers that were non-detects. The criteria for flagging non-detects comprised the following:

- Large changes in detection limit resulting from a change in analytical procedure, typically a difference between analyses during 2004 and all subsequent analyses.
- Non-detects that were higher than other detected values.

In the case of surface water, a specific sub-set of non-detects for bismuth was also flagged. These samples comprised a set of analyses during the fourth quarter of 2007 from a specific laboratory. This laboratory analyzed primary and duplicate samples and was used only during this period. The reported detection limits for these analyses were 40 or 80 micrograms per liter (µg/L). These detection limits were many times higher than the highest detection limit of all other bismuth analyses (0.69 µg/L) and were not confirmed by any of the triplicate analyses.

Based on this methodology, the numbers of confirmed outliers identified were as follows:

- 1,428 surface water analyses (922 for dissolved and 506 for total concentration) in the mine study area (Appendix 9.1D).
- 1,271 groundwater analyses (503 for dissolved and 768 for total concentration) in the mine study area (Appendix 9.2C).
- 43 surface water analyses (18 for dissolved and 25 for total concentration) in the transportation corridor study area (Appendix 9.3A).
- One dissolved groundwater analysis in the transportation corridor study area (Appendix 9.4A).

In all, the number of outliers was small (0.6 percent) considering that 443,361 analyses were completed. All data points flagged as outliers were excluded from the plots, statistics, and interpretation presented in Sections 9.1 through 9.4.

Statistical evaluation of the non-rejected surface-water data was presented using box-and-whisker plots in Appendix 9.1G and 9.1K. These plots include the terms "outlier" and "extreme outlier". The terms used in these plots are distinct from the above discussion of outliers, which described the criteria used to exclude data from evaluation. Instead, these terms were used in Appendix 9.1G and 9.1K to describe values that were considered extreme in relation to the overall data distribution. No data points identified as "outliers" or "extreme outliers" in Appendix 9.1G or 9.1K were excluded from evaluation in this chapter.

9.0.6.7. Logarithmic Scales

Logarithmic scales were often used to plot concentration data that varied over a wide range to make the concentrations easier to distinguish over the full range. For example, arsenic concentrations in groundwater ranged from about 0.02 µg/L to about 50 µg/L. If these concentrations were plotted on an arithmetic scale, the concentrations at low values would be difficult to distinguish. However, plotting

these same concentrations on a logarithmic scale made the concentration easier to distinguish over the full range. Logarithmic scales have this effect because each factor of 10 on a logarithmic scale is represented by an equal distance on the graph (Figure 9.0-3). For example, the distance between 0.01 and 0.1 on a logarithmic scale is the same as the distance between 0.1 and 1.0, and similarly the distance between 0.1 and 1.0 is the same as the distance between 1.0 and 10 (Figure 9.0-3). This approach to scaling leads to non-uniform scaling in-between factors of 10. For example, the distance between 0.1 and 0.2 is greater than the distance between 0.2 and 0.3, which in turn is greater than the distance between 0.3 and 0.4 (Figure 9.0-3). However, the concentrations between the factors of 10 are easily distinguished by the tick marks on the scale. Each tick mark represents an increment appropriate to the factor of 10 to which it applies. For example, between 0.1 and 1.0, each tick mark represents an increment of 0.1 (Figure 9.0-3). Similarly, between 1.0 and 10, each tick mark represents an increment of 1.0. By counting the tick marks up to the measured concentration, the concentration can be easily distinguished. In cases where the concentration falls between two tick marks, the concentration can be estimated. As a hypothetical example, concentrations that range from 0.04 to 7.0 mg/L can be easily distinguished when plotted on a logarithmic scale but are difficult to distinguish when plotted on an arithmetic scale (Figure 9.0-3).

9.0.6.8. Piper Plots

Whereas most plots of water chemistry represent the absolute concentrations of individual constituents, a Piper plot is used to represent the composition of the major ions of a water sample. The major ions in natural waters include the following cations and anions:

- Cations: Ca^{2+}, Mg^{2+}, Na^{+}, K^{+}
- Anions: HCO_3^{-}, CO_3^{2-}, SO_4^{2-}, Cl^{-}

The composition of each water sample can be calculated by determining the percentage of total milli-equivalents that each ion represents. Because the anions HCO3 and CO3 play the same role in buffering the pH of water and because they are typically determined as a sum with an acid-base titration, they are plotted together on the Piper plot as HCO3+CO3. In the cation category, the concentration of potassium is usually small compared to the other cations, so potassium and sodium are also plotted together on the diagram as Na+K.

The Piper plot structure is a composite of three diagrams (Figure 9.0-4):

- one ternary diagram (triangle with three axes) for cations;
- a second ternary diagram for anions; and
- a combined diagram for anions and cations.

Each sample is represented by a point in each of these three diagrams. The location of the point in each of the cation and anion ternary diagrams is determined by the cation and anion composition, respectively (Figure 9.0-4). The location of the point on the combined diagram is determined by projecting each of the points into the combined diagram (Figure 9.0-4).

An example of concentrations in an actual water sample is as follows (expressed in milli-equivalents per liter):

CATIONS			ANIONS		
Concentration (meq/L)		% of Total Cations	Concentration (meq/L)		% of total Anions
Ca:	0.06587	44%	HCO3+CO3:	0.10312	71%
Mg:	0.02197	15%	SO4:	0.02854	20%
Na+K:	0.0609	41%	Cl:	0.01374	9%
Total	0.14874	100%	Total:	0.1454	100%

The "% of Total Cations" and "% of Total Anions" are determined by dividing the milli-equivalents of each parameter by the total milli-equivalents. An example calculation of "% of Total Cations" for calcium is as follows:

$$\% \text{ of Total Cations for Ca} = \frac{0.14874}{0.06587} = 0.443 = 44\%$$

This calculation is repeated for each of the constituents to determine the percentage for each one. The cation composition is then plotted on the ternary diagram for cations (Figure 9.0-4). The scale for calcium is read along the bottom of the cation diagram from right to left, and is projected up and to the left. The scale for magnesium is read along the left-hand side of the triangle and is projected horizontally to the right (Figure 9.0-4). Finally, the scale for Na+K is read along the right-hand side of the diagram from upper left to lower right, and is projected down and to the left. Each of these scales is represented within the diagram by its own set of dashed lines. The intersection of these three lines defines the location of the point in the cation ternary diagram (Figure 9.0-4). This procedure is repeated for the anion composition, and the point is plotted at the intersection of the three lines on the anions diagram (Figure 9.0-4). These two points are then projected into the combined diagram to show the overall anion and cation composition. In this fashion, geochemical facies can be defined within the combined diagram to represent ranges of composition that allow the geochemical composition of the water to be classified.

9.0.6.9. Other Data Reduction Methods

Data reduction that was particular to either surface water or groundwater sampling in either the mine study area or transportation corridor is described in the respective sub-sections.

9.0.7. Approach to Comparison with Water Quality Criteria

The results of the surface water and groundwater quality sampling were compared with the most stringent benchmark water quality criteria that were derived from Title 18 of the Alaska Administrative Code, Chapter 75 (18AAC75), and Alaska Water Quality Criteria (ADEC, 2008; Tables 9.0-2 and 9.0-3). Because these criteria are specific to surface water, the comparisons of groundwater concentrations were not intended to indicate whether these natural concentrations met a given standard. Rather, the

groundwater concentrations were compared with the surface-water criteria to provide context for the sampling results.

Each surface-water and groundwater sample was compared to the criterion by dividing the constituent concentration by the respective criterion. The criterion for pH is a range, the criterion for alkalinity is a lower bound and the criteria for all other parameters is an upper bound. Therefore, except for pH and alkalinity, a ratio greater than one indicated that the concentration was greater than the most stringent maximum ADEC criterion. For alkalinity, a ratio less than one indicated that the concentration was lower than the most stringent minimum ADEC criterion. For pH, a ratio greater than one relative to upper end of the range or a ratio less than one relative to the low end of the range indicated that the pH was outside the range for the most stringent ADEC criterion. Some of the criteria depend on the water hardness. These hardness-dependent criteria are considered preliminary because the metholodology for establishing the appropriate hardness values remains to be determined.

9.1. Surface Water—Mine Study Area

This section presents the findings of an environmental baseline study of surface water quality in the mine study area. From April 2004 through December 2008, samples were collected for laboratory analysis to evaluate water quality of naturally occurring constituents (NOCs) at streams, seeps, and lakes within the study area. The data will be used to characterize the environment.

Stream water quality data and samples were collected from 44 stream sample locations during 50 sampling events (seven events in 2004, nine events in 2005, 10 events in 2006, 12 events in 2007, and 12 events in 2008). Samples were collected across several months in most years and were collected in all months in both 2007 and 2008. Therefore, the collected data characterize water quality during winter low-flow, spring breakup, summer low-flow, and fall precipitation events.

Seep water quality data and samples were collected from 11 locations in March and September 2004, 24 locations in July and October 2005, eight locations in March 2006, 25 locations in June 2006, 24 locations in August 2006, and 59 locations in October 2006. In 2007, 12 seep locations were sampled in March, 65 locations in May, 100 locations in August, 102 locations in September, and 114 locations in October. In 2008, 19 seep locations were sampled in June, and 28 locations each were sampled in August, September, and November. Data were collected to characterize water quality during spring runoff, summer low flow, and fall rains.

Lake water quality data and samples were collected from 19 lakes in July and August 2006, and August 2007. Data were collected to characterize water quality of lakes in the study area during the summer.

Elements common across all types of waterbodies are discussed in Sections 9.1.1 through 9.1.7 (e.g., objectives, scope of work, sample locations). Stream water quality is discussed in Section 9.1.8, seep water quality is discussed in Section 9.1.9, and lake water quality is discussed in Section 9.1.10.

9.1.1. Study Objectives

The stream, seep, and lake water quality program is conducted in conjunction with the hydrology baseline study of surface water (Chapter 7 of this environmental baseline document [EBD]). The program is designed to describe and characterize the water chemistry throughout the year under a range of hydrologic conditions at key locations across the three main watersheds in the study area (Figure 9.1-1). In addition, Kaskanak Creek was studied at one location to compare and contrast with water chemistry in the three main watersheds, in the expectation that no hydrologic connection between the Creek and these watersheds is present. Hydrologically notable events, such as winter low flow and spring breakup, are targeted for water quality sampling. Water quality data are compared to water quality criteria as benchmarks and to other relevant studies as available.

The objectives associated with this study are consistent with those outlined in the consolidated study program for Pebble Project (a copy of which is provided in Appendix E of the EBD) and include the following for streams, seeps, and lakes, respectively.

Specific goals and objectives of the stream sampling program discussed in Section 9.1.8, and the lake sampling program discussed in Section 9.1.10, include the following:

- Collect baseline data to provide scientific documentation of the NOCs, their concentrations, and their variability in surface water.
- Provide a database of site water chemistry.

Specific goals associated with the seeps study described in Section 9.1.9 were developed to meet the overall study objectives, including the following:

- Identify the number of seeps and their locations in the mine study area, and characterize the flow and water chemistry in selected seeps during select times of the year that represent specific flow conditions.
- Establish baseline conditions of NOCs in seeps within the mine study area.
- Identify major factors influencing constituent distribution.

This study advances the overall goal of the hydrological program to characterize surface water expression in the mine study area.

9.1.2. Study Area

The mine study area encompasses 392 square miles and is drained by the North Fork Koktuli River, South Fork Koktuli River, and Upper Talarik Creek (Figure 9.1-1). Kaskanak Creek is in a separate drainage without a direct relationship to the deposit area but is included in the study area to compare and contrast NOC data with the other three river systems. The deposit area, located roughly in the middle of the mine study area, is at an elevation of about 1,150 feet. This location is approximately 2 miles north of a lake, locally named Frying Pan Lake (elevation 943 feet), in the headwaters of the Koktuli River and Upper Talarik Creek.

The North Fork and South Fork Koktuli rivers drain into the Nushagak River and out into Bristol Bay. Kaskanak Creek drains into the Kvichak River, south of Iliamna Lake. Upper Talarik Creek drains into Iliamna Lake, which in turn drains into the Kvichak River.

9.1.3. Previous Studies

Cominco Alaska Exploration (Cominco) (currently doing business as Teck Alaska) began to explore the mine study area in 1986. Drilling started in 1988 and continued through 1993. Water quality sampling was initiated by Cominco during June 1991 at 10 sites (unpublished data). These sites were each sampled five times between June and July 1991 for 24 elements: aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc. From August 1991 to November 1993, the original 10 sites were abandoned and monitoring began at five new sites. These new sites were sampled approximately once every month for 10 elements: arsenic, barium, cadmium, chromium, copper, lead, mercury, molybdenum, selenium, and silver.

Three of the 10 Cominco sites sampled during June and July 1991 correspond to current sample locations under the Pebble Project. Cominco sites 5, 6, and 8 correspond to Pebble Project sample locations SK100D, SK100G, and UT100E, respectively (Figure 9.1-2). Data from June and July 1991 for these three sites have detectable results for only seven (aluminum, calcium, iron, magnesium, manganese,

sodium, and zinc) of the 24 constituents tested. The other 17 constituents were not detected by the analytical laboratory.

Three of the five Cominco sites sampled between August 1991 and November 1993 correspond to current sample locations under the Pebble Project. Cominco sites 13, 14, and 17 correspond to Pebble Project sample locations UT100D, SK100G, and SK100F, respectively (Figure 9.1-2). Barium was the only constituent consistently identified above detection limits in these historical samples. Cadmium and chromium were occasionally reported at detectable levels. The North Fork Koktuli River and Kaskanak Creek drainage areas were not sampled by Cominco.

Because of recent improvements in the sensitivity of analytical methods, the laboratory detection limits for constituents in the early 1990s were higher than current detection limits. Most Cominco method reporting limits (MRLs) were at least an order of magnitude higher (some as many as three orders of magnitude) when compared to the current MRLs. Cominco project MRLs and Pebble Project MRLs are presented and compared in Table 9.1-1.

The Cominco water quality data have limited usability for historical comparison to the water quality analytical results from the current Pebble Project sampling program for the following reasons:

- Only a few Cominco sites correspond with current study area sample locations for baseline water quality.
- Very few results from the Cominco sites were above the MRLs.
- Detection limits were substantially higher in the Cominco samples than in the current program.

Therefore, only the Pebble datasets are further considered in this evaluation.

9.1.4. Scope of Work

The field work for this 5-year portion of the baseline study was conducted from April 2004 through December 2008. CH2M Hill, Inc. (CH2M Hill) collected the data from April to September 2004. HDR Alaska, Inc. (HDR) completed the study tasks during the remainder of the 2004 calendar year, and HDR was responsible for collecting all data from January 2005 through December 2007, with the exception of three Alaska Peninsula Corporation (APC) sites on Upper Talarik Creek and sample location NH100APC1 on the Newhalen River. APC began collecting data on these four locations in August 2007. HDR and SLR Alaska (SLR) jointly collected the pond water samples.

APC began sampling all Upper Talarik Creek and Newhalen River sites in January 2008, and HDR continued to collect data on the South and North Fork Koktuli rivers, main stem Koktuli River, and Kaskanak Creek. Water quality samples were collected from stream surface water within the mine study area, and sediment samples were collected from a subset of surface water sample locations. Sediment is further discussed in Chapter 10 of the EBD. All sampling locations discussed in Section 9.1 are shown on Figure 9.1-2.

At the time of sample collection, the following field parameters were measured and recorded:

- Dissolved oxygen (DO) measured as concentration (milligrams per liter [mg/L]) and percentage.
- pH.

- Oxidation reduction potential (ORP).
- Specific conductivity.
- Turbidity.
- Water temperature.
- Surface water velocity.

The analytical and field measurement data for trace elements, ions, and field and physical parameters were collected over a 5-year period from April 2004 to December 2008. Stream, seep, and lake samples were all analyzed for the same set of constituents (Table 9.1-3). A summary of the NOC parameter results from these samples is provided in Appendix 9.1B.

9.1.4.1. Streams

The scope of work for the stream water quality samples under the surface water program for rivers described in Section 9.1.8 included the following tasks:

- Collection of depth-integrated composite or grab water quality samples at 44 stream sample locations during 50 sampling events from April 2004 through December 2008.
- Measurement of field parameters at the stream sample locations for each sampling event.

Table 9.1-2 contains the period-of-record index by sample location for activities related to the stream surface water quality program during April 2004 through December 2008. The table identifies the months in which measurements were made and samples were collected. Sampling locations for streams are shown on Figure 9.1-3. Photographs of the stream sampling locations in different seasons are provided in Appendix 9.1A. Sampling locations for streams are shown on Figure 9.1-3.

The number of samples collected from each sampling location varied slightly for several reasons. Because of weather conditions, lack of access, or lack of flow, not all stream locations were sampled during each sampling event. For most locations, these factors resulted in fewer stream surface water samples being collected from tributaries than from main stem sampling locations. Sampling locations were also added and removed at different times throughout the program resulting in varying lengths of record between sites. Additionally, water quality sample collection became more systematic and more frequent as the program evolved. For most locations, the fewest samples per year were collected during the first year of sample collection (2004). The number of stream samples collected yearly increased until 2007, when regular scheduled sampling began across all locations; however although the regularly scheduled sampling continued into 2008, the total number of samples collected in 2008 declined overall because fewer sampling locations were included in the program.

In addition to the analyses discussed above, a subset of stream samples was analyzed for petroleum hydrocarbons (gasoline range organics [GRO], diesel range organics [DRO], and residual range organics [RRO]), volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), polychlorinated biphenyls (PCBs), and pesticides. None of the compounds in these analytical suites were detected at concentrations above MRLs, so they are excluded from further evaluation. A summary of the organic parameter results from these samples is provided in Appendix 9.1B.

9.1.4.2. Seeps

The following scope of work was conducted for the baseline evaluation of seeps in the mine study area from 2004 through 2008.

- 2004:
  - Collection of 18 grab water samples from 11 seep sample locations in May and September for chemical analysis of trace metals, ions, and flow measurements.
  - Measurement of field parameters (temperature, specific conductivity, DO, pH, ORP, and turbidity) at the seep sample locations for each sampling event.
- 2005:
  - Collection of 88 grab water samples from 29 seep sample locations in March, July, and October for chemical analysis of trace metals, ions, and flow measurements.
  - Measurement of field parameters (temperature, specific conductivity, DO, pH, ORP, and turbidity) at the seep sample locations.
- 2006:
  - Collection of 118 grab water samples from 59 seep sample locations in March, June, August, and October for chemical analysis of trace metals, ions, and flow measurements.
  - Measurement of field parameters (temperature, specific conductivity, DO, pH, ORP, and turbidity) at the seep sample locations for each sampling event.
- 2007:
  - Collection of 412 grab water samples from 127 seep sample locations in March, May, August, September, and October for chemical analysis of trace metals, ions, and flow measurements.
  - Measurement of field parameters (temperature, specific conductivity, DO, pH, ORP, and turbidity) at the seep sample locations for each sampling event.
- 2008:
  - Collection of 66 grab water samples from 28 seep sample locations in June, August, September, and November for chemical analysis of trace metals, ions, and flow measurements.
  - Measurement of field parameters (temperature, specific conductivity, DO, pH, ORP, and turbidity) at the seep sample locations for each sampling event.

NOCs were analyzed in 650 seep samples over the 5-year period. Seep water quality data are discussed in Section 9.1.9. Seep sampling locations are shown on Figure 9.1-4, and photographs from sampling events are provided in Appendix 9.1C. The comprehensive seep inventory is shown on Figure 9.1-5.

9.1.4.3. Lakes and Ponds

The following scope of work was conducted for the baseline evaluation of lakes in the mine study area in 2006 and 2007.

- 2006:
  - Collection of 28 grab water samples from 19 lakes in July and August for chemical analysis of trace metals, ions, and miscellaneous parameters.
  - Field measurements were collected at each of the 28 sampling locations.
- 2007:
  - Collection of 19 grab water samples from 19 lakes in August for chemical analysis of trace metals, ions, and miscellaneous parameters.
  - Field measurements were collected at each of the 28 sampling locations.

Constituents were analyzed in 47 samples over the 5-year period, as discussed in Section 9.1.10. Lake surface water sampling locations are shown on Figure 9.1-6.

9.1.5. Methods

9.1.5.1. Water Quality Stream Sample Location Selection and Nomenclature

Selection and development of sample locations was coordinated with other baseline program teams, including those studying hydrology, fish, aquatic resources, sediment, and trace elements. Twenty-nine sample locations were selected in 2004 for water quality measurements. Three sample locations were added in 2005. These locations were selected based on the following considerations:

- Characterization of drainage areas.
- Historical (Cominco) baseline sample locations.
- Groundwater and surface water interactions.
- Locations upstream and downstream of the deposit area.
- Surface waterbodies in the general vicinity of the deposit area.
- Feedback from the Pebble Project hydrology, fish, aquatic resources, sediment, and trace element baseline program teams.

Nomenclature for identifying stream sample locations (Figure 9.1-3) is described below:

- KC = Kaskanak Creek.
- KR = Koktuli River.
- NH = Newhalen River.
- NK = North Fork Koktuli River.
- SK = South Fork Koktuli River.
- UT = Upper Talarik Creek.
- APC = Indicates sites located on APC land.

- Main stem channels are designated as 100, and each tributary stream is numbered in a sequential upstream fashion (101, 102, etc.).
- Each stream identification number is followed by a sequential letter that is a sample location identifier (A, B, C, etc.); an "A" denotes the most downstream sample location on a stream or tributary.

For example, sample location UT119A refers to the most downstream sample location on the 19th mapped tributary to Upper Talarik Creek from its mouth. Sample location SK100B refers to the second most downstream sample location on the main stem of the South Fork Koktuli River.

Three sample locations (SK100B, NK100A, and UT100B) for U.S. Geological Survey (USGS) hydrologic surveys were installed during the July 2004 field trip; these locations were added to the sample inventory. Several sample locations initially selected by CH2M Hill in April 2004 were moved either upstream or downstream of the initial location, or they were removed from or added to the program. Sample locations that were dropped are NK100D, SK100E, UT100C, and UT135B. Locations KC100A, NK100A, NK100B, NK100C, NK119A, and NK119B were moved after the first month or two of data collection in 2004. Three new stream sample locations were added in 2005 (SK124A, SK100B1, and SK100B2).

9.1.5.2. Seep Sample Location Selection and Nomenclature

Seep sample locations were identified with either "SP" or "SRK," followed by a unique two- to four-digit number. The seep program sample locations are shown on Figure 9.1-4. The seep sampling site locations and sampling frequencies evolved over the 5-year study period.

The seeps inventory program documented the location and relative size of seeps within the mine study area. The seep inventory areas were defined and selected by Schlumberger Water Services, (formerly known as Water Management Consultants), using a variety of criteria including upwelling areas, and inter-basin transfers. The working definition of a seep used for the purposes of this task is defined as follows:

- Seep exhibiting a distinct groundwater point source and distinct flow path extending downslope approximately 30 feet or until it entered a larger drainage feature, or
- Large diffuse seep areas with dry ground up-gradient and that coalesced into a distinct flow path down-gradient.

Features that were ***not*** mapped include the following:

- Small features that appeared to be directly reabsorbed downslope.
- Small drainages with accumulating surface runoff.
- Meltwater features that coalesced below snowfields.
- Marshy areas and ponds with no distinct flow path below the feature.

Seeps inventories were conducted via aerial surveys with helicopter support. All inventory areas were overflown in a helicopter at altitudes ranging from 50 feet to 150 feet above ground level. Initially, inventory areas were canvassed at the higher altitude and speed to conduct a reconnaissance of the seeps.

A more detailed inventory was then conducted at the lower altitude to achieve 100-percent coverage. The Global Positioning System (GPS) track log feature was used to assure all areas were canvassed. The seeps were marked with waypoints in order to locate them on the ground. Seep inventories were conducted during several open-water conditions and runoff regimes. The seep inventory locations are shown on Figure 9.1-5.

9.1.5.3. Water Quality Stream Field Measurement

The field team measured field parameters in situ and collected water samples during each stream water quality sampling event. Data were collected in accordance with the consolidated study program for Pebble Project (Appendix E of the EBD), the Field Sampling Plan (FSP; Appendix F of the EBD), and the Quality Assurance Project Plan (QAPP; Appendix G of the EBD). Quality assurance (QA) and quality control (QC) procedures were followed during sample collection, processing, and shipping.

In 2004, a Hydrolab Quanta multiprobe meter was used to measure specific conductivity, water temperature, pH, ORP, and DO in the field. In subsequent years, the team members switched to the YSI 556 multiprobe meter to collect field parameters. Otherwise, the measurements were made consistent with the FSP and QAPP.

Analytical surface water samples were collected using the appropriate technique for the field conditions at the time of the sampling. For example, during periods of open-water conditions and where adequate depths (greater than 1 foot of water) permitted use of depth-integrating equipment, stream samples were collected with a DH-48 sampler in 2004 and a DH-81 sampler in later years. Grab sampling was necessary in shallow streams and during freeze-over periods. Grab sampling was also used for safety reasons during high-flow conditions when the water was likely to be thoroughly mixed due to high turbulence.

The field team filtered all water samples to be analyzed for dissolved elements through 0.45-micron capsule filters using a peristaltic pump and surgical tubing at the base camp in Iliamna. These samples were filtered and preserved, in accordance with the QAPP, within 12 hours of collection. Dissolved concentrations were occasionally greater than total concentrations of the same constituent, either due to natural variability in analytical results, or possibly as a result of the type of filter used for the study, or possibly due to field contamination during filtering. In response, the FSP was amended to include the use of a filtering hood to eliminate airborne particles during filtration.

In addition, stream samples were collected in August and October 2004 and July 2005 for analysis of some organic compounds (petroleum hydrocarbons, pesticides, PCBs, VOCs, and SVOCs). These methods, individual compounds, and MRLs can be found in the QAPP (Appendix G of the EBD).

QA/QC samples were collected during each sampling event in accordance with the QAPP (Appendix G of the EBD). These included duplicates, triplicates, matrix spike/matrix spike duplicates, filtered equipment rinsate, filtered deionized water, and nonfiltered deionized water. Trip blanks provided by the laboratories were kept with the samples during sample collection and shipment. After the sampling team returned from the field and filtered samples for dissolved constituent analyses, the samples were transferred to a representative of Shaw Alaska, Inc. The Shaw representative completed chain-of-custody forms, ensured samples were properly preserved and refrigerated, packed samples, and shipped samples to the analytical laboratories. Primary samples were sent to and analyzed by SGS Environmental Services,

Inc. (currently doing business as SGS North America, Inc. [SGS]) in Anchorage, Alaska. Columbia Analytical Services in Kelso, Washington, received and analyzed QA/QC samples. Samples were analyzed for the parameters listed in Table 9.1-3.

9.1.5.4. Water Quality Seep Sample Collection

The field sampling work consisted of sampling a representative subset of the inventory sites for surface water quality and flow. Within this subset, surface water samples and flow measurements were taken at each seep sampling site up to five times per year to capture water base flow (March to April), spring breakup (May to June), summer low flow (August), a fall event (September), and late flow (November). The timing of sampling events varied from year to year due primarily to access limitations caused by weather, and all of the seasonal variation could not be captured each year during sampling; for example, only four sampling events could be conducted in 2008. Only field parameters were collected at three of the 28 locations in 2008. Analytical and field data were both collected and analyzed at 25 locations in 2008.

The field team measured in situ field parameters and collected water samples during each sampling event. Sample collection, processing, and shipping followed the protocols of the consolidated study program for Pebble Project (Appendix E of the EBD), the FSP (Appendix F of the EBD), and the QA/QC procedures outlined in the QAPP (Appendix G of the EBD)

Team members collected seep water samples for laboratory analysis of total and dissolved trace metals, major ions, and field and physical parameters (Table 9.1-3). On the initial visit to a sampling location, a GPS point was recorded, a fiberglass stake was placed in the ground, and the station was “developed.” Development entailed selecting a location that would capture the maximum percentage of the seep flow while maintaining repeatability and consistency of the flow measurement. Often, several smaller flows were channelized to a location with suitable characteristics for capturing the flow. Any channeling of flows was also documented at that time with sketches and photographs. The seep flow substrate was smoothed and reshaped to accept the portable weir or to create a free overfall for direct catch. Large rocks and other obstructions were removed. On return visits, collection ditches were maintained for repeatability of the flow measurement. During spring events, snowdrifts occasionally necessitated sampling at locations that were near, but not exactly at, the original location.

Due to the variability in the size of seeps, two methods and/or apparatus were used to measure discharge:

- Direct Catch: This method was used for seeps with small flows and as a supplementary method on mid-sized seeps to calibrate the weir flow data. Direct flow was captured over a timed period in a calibrated container. Direct catch was limited to flows that could be captured in a 5-gallon bucket in 2 to 3 seconds. This method is quick and repeatable. It was the preferred method where applicable.
- Portable Weirs: Four portable weirs were used on this project: 60-degree, 90-degree, and 120-degree V-notch weirs and a 3-foot rectangular weir. The size of the weir used was dependent on the amount of the seep flow. All of the weirs were fitted with a rubber skirt that conformed to the bottom of the flow channel. Sediments, mud, moss, and rocks were used to seal the skirt along its upstream edge, and static water pressure held the weir and skirt in place. The water head above the crest of the weir was then recorded. Estimated percentage of the total flow captured was

recorded. Conditions that affected this percentage were the shape and slope of the channel, the coarseness and gradation of the substrate, and the availability of sealing materials (mud, moss, sand, etc.). Once a station was established, the percentage of capture remained approximately equal for successive sampling events.

The flow measurement methods outlined above were intended to give relative and repeatable flow values in order to compare flows at different times of the year and in different weather, groundwater, and precipitation events. These different sampling techniques are shown in the first few photographs of Appendix 9.1C.

9.1.5.5. Seep Review Methodology

Due to the large number of seeps monitored during previous years, SWS reevaluated the seep program at the start of the 2008 season with the goals of reducing redundancy in aerial coverage and focusing attention on seeps deemed more representative of site conditions and presenting greater potential for contribution to the local surface water system. Based on geographic location, size, water chemistry, and aquifer type, 28 of the original 127 sampled sites were selected for sampling in 2008. As indicated in the February 2008 memorandum issued by Schlumberger Water Services to Northern Dynasty Mines, Inc. (NDM; now Pebble Partnership), SGS reviewed each of the 127 seeps on the 2007 monitoring list, considering the following attributes:

- Seeps in close proximity to each other.
- Seep flow rate.
- Seep water quality (based on both field index parameters and chemical analyses).
- Bedrock geology.
- Surficial geology area coverage, watershed, and proximity to stream monitoring stations.
- Elevations.

A combination of the seep attributes indicated above was considered in judging the relative importance of the seep and classifying the seeps into three categories as follows:

- H – High – overall importance is high if any attributes were designated high, or seep presents unique site location or geologic setting.
- M – Medium – overall importance is medium when attribute importance does not warrant high designation, yet also some of the attributes are above low importance.
- L – Low – overall importance is low when no attribute importance exceeds low designation.

The “high” category comprises 30 seeps distributed over the study area, with the highest density near the deposit area. These 30 seeps cover all geological units. High importance was given in particular to those seeps with elevated sulfate and trace metals.

The “medium” category comprises 46 seeps. Most of the M-category seeps were recommended for removal from the regular monitoring list due to possible duplication or similar lithological type or chemistry relative to nearby seeps.

The “low” category of seeps includes mostly those with low (less than 0.01 cubic feet per second) or zero flow during dry season. Almost all “low” category seeps were recommended to be removed from the regular seep monitoring program. Other seeps of this category mostly reflect duplicate locations, discharging from the same geologic unit, and have typical chemistry as other seeps with more flow.

Based on the above analysis of the seeps, Water Management Consultants recommended monitoring only 28 seeps during 2008. The seeps were distributed in each watershed as follows:

- North Fork Koktuli River drainage – 7 seeps.
- South Fork Koktuli River drainage – 9 seeps.
- Upper Talarik Creek drainage – 12 seeps.

The seeps recommended for monitoring generally have moderate to high flow rates during the dry time of year. The seeps provide overall general coverage of the mine study area and also are representative of various elevation intervals and almost all geologic settings across the site. Most (21 of 28) of the seeps recommended for monitoring are in the “high” category, and the remaining seven are in the “medium” category.

None of the South Fork Koktuli River drainage seeps located in the immediate area of the Pebble Deposit were included on the 2008 monitoring list because a significant amount of data is already on record for these locations. Also, seeps that demonstrated high water temperature were not included for additional monitoring because these seeps are considered to originate from nearby surface water with short underground residence time.

Spatial and temporal trend analysis was conducted for a subset of seeps in each watershed. The seeps evaluated from each drainage area were selected based on their unique characteristics and impact on overall surface water quality (e.g., high-flow seeps were preferentially selected over low-flow seeps) as discussed earlier in this section. The seeps and their rationale for inclusion based on the criteria developed by SWS are presented in Table 9.1-4.

9.1.6. Data Reduction

This section summarizes how the raw data were processed and evaluated. Only primary sample data were used for analyses in this EBD. Duplicate and triplicate sample data were used only for evaluation of precision. Some results were rejected during data validation; the majority of these were dissolved-constituent data. These rejected results were excluded from the datasets, resulting in fewer results for some constituents. Only sample locations from which analytical data were usable, as determined by the data validation process, were evaluated. Both field and laboratory data were available for pH; but only field pH data were incorporated into the quantitative evaluation because these measurements were more representative of field conditions than laboratory pH data. Laboratory pH data were only used to determine the pH at the time of laboratory analysis and are not relevant to baseline data.

Summary statistics were first developed for all data compiled from 2004 through 2008 for all seasons and watersheds to obtain general information on the ranges of constituent concentrations, distribution of data, and its variability. Stream, seep, and lake data were evaluated separately. Data were also separately

compiled and summarized by watershed to make general comparisons in data variability across the North Fork Koktuli River, South Fork Koktuli River, Upper Talarik Creek, and Kaskanak Creek drainages.

The following general statistics were compiled for each dataset:

- Minimum and maximum detected concentrations.
- Sample-specific minimum and maximum method detection limits (MDLs) and MRLs.
- Number of results detected.
- Number of samples analyzed.
- Frequency of detection.
- Arithmetic mean and median concentrations.
- Standard deviations and coefficients of variation.

Non-detect results were included for statistical summaries as one-half the MDL, . For all other statistical analyses, only detected concentrations, including estimated results below the detection limit, were included to avoid skewing the datasets based on multiple non-detect values. Statistical summary tables for North Fork Koktuli, South Fork Koktuli, Upper Talarik Creek, and Kaskanak Creek systems are provided as Tables 9.1-5 through 9.1-8, respectively.

Except for spatial analyses, all sampling locations were included in the evaluation. For spatial analyses, only data from main stem sample locations were included. Tributary data were not included in the spatial analysis so the main stems of the three main river systems could be directly compared.

The statistical analyses presented later in this section were performed for total and dissolved trace elements, major ions, field and physical parameters, and cyanides.

In addition, the data for a subset of 25 seeps identified by SWS for continued monitoring in 2008 were separated by watershed, and seeps within each watershed were grouped by seep discharge velocity to evaluate the potential effect of groundwater discharge on trace elements concentrations.

9.1.7. Outlier Analysis

Outliers are points in a dataset that represent a rare event, belong to a different population (contamination, disequilibrium), or indicate an analysis error. As part of the QA/QC measures, outliers that were considered to be errors, or considered to not represent the ambient groundwater, were documented in the dataset. As summarized in Section 9.0.6.6, 1,428 outliers were identified in the mine study area.

Most samples had no flagged data points. Samples with flagged data points typically had only one or two results flagged. This included 117 of the 17,060 stream surface water data points in the North Fork Koktuli River, 329 of the 49,098 surface water data points in the South Fork Koktuli River, and 363 of the 36,199 surface water data points in the Upper Talarik Creek. Overall, the percentage of outliers was very small for the 102,357 stream surface water data points (0.79%). The number of outliers identified in the seep dataset (521 of the 47,617 seep data points; 1.1%) was slightly greater than in the stream samples, but also represented a very low percentage of the data points. The outlier analysis is graphically presented in Appendix 9.1D.

Statistical evaluation of the non-rejected surface-water data was presented using box-and-whisker plots in Appendix 9.1G and 9.1K. These plots include the terms "outlier" and "extreme outlier". The terms used in these plots are distinct from the above discussion of outliers, which described the criteria used to exclude data from evaluation. Instead, these terms were used in Appendix 9.1G and 9.1K to describe values that were considered extreme in relation to the overall data distribution. No data points identified as "outliers" or "extreme outliers" in Appendix 9.1G or 9.1K were excluded from evaluation in this chapter.

9.1.8. Streams

9.1.8.1. Results and Discussion: North Fork Koktuli River

This section presents the findings of the surface water quality study in the North Fork Koktuli River drainage. Surface water samples and measurement of physical and chemical parameters were obtained from the river and its tributaries to establish baseline conditions and to assess the spatial and temporal variability of field and physical parameters, major ions, nutrients, trace elements, and cyanides in the drainage. The analysis was conducted using data acquired during the 5-year period from 2004 to 2008.

The North Fork Koktuli River study area includes one tributary and encompasses approximately 20 miles of the main stem, originating from just north of Big Wiggly Lake and ending at the confluence with South Fork Koktuli River. Sampling locations are greater than 1 mile away from the general deposit area.

Two hundred forty one surface water samples were collected and analyzed from seven sampling locations in the North Fork Koktuli River and its tributary between 2004 and 2008. The results from these analyses are presented in Table 9.1.5.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, cyanides, and organic compounds.

Field and Physical Parameters

Eight field and physical parameters were measured in North Fork Koktuli River surface water samples, including total dissolved solids (TDS), field pH, DO, water temperature, field-specific conductivity, turbidity, total suspended solids (TSS), and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-5. The overall coefficient of variation (CV) for this group was 0.81, which is similar to that of the South Fork Koktuli River and Upper Talarik and Kaskanak Creeks.

Total Dissolved Solids. The frequency of detection (FOD) for TDS was 99 percent. TDS was detected at a mean concentration of 37 mg/L. The CV for TDS was 0.035. TDS is low relative to rivers in more-developed areas.

pH (Field). The mean pH in North Fork Koktuli River samples was 6.74. The CV for pH was 0.10, consistent with a tight data distribution. A pH median of 6.77 (pH units) indicates that the water in the North Fork Koktuli River is slightly acidic.

Dissolved Oxygen. DO was detected at a mean concentration of 10.2 mg/L. The CV for DO was 0.2. Overall, DO measurements indicated the surface water is well aerated.

Water Temperature. The mean water temperature was 4.39 degrees Celsius (^{o}C). The CV for water temperature was 1.12. Temperature fluctuates seasonally, but generally water temperature is cold, at a median temperature of 1.85^{o}C.

Specific Conductivity (Field). Specific conductivity was present in all samples at a mean concentration of 46.0 microSiemens per centimeter (uS/cm). The CV for specific conductivity was 0.31.

Turbidity. The mean concentration for turbidity was 1.33 nephelometric turbidity units (NTU). The CV for turbidity was 1.79, with variability similar to that for TSS. Turbidity is generally low in the North Fork Koktuli River, as indicated by the mean concentration of 1.33 NTU.

Total Suspended Solids. The FOD for TSS was 81 percent. TSS was detected at a mean concentration of 1.39 mg/L. The CV for TSS was 1.9, indicating a much wider fluctuation of concentrations than for TDS. However, as for TDS, TSS is low relative to rivers in more-developed areas.

Oxidation Reduction Potential. ORP was detected in all samples at a mean concentration of 133 millivolts (mV), with a range of -182 mV to 345 mV. The CV for ORP was 0.69.

Major Ions

North Fork Koktuli River surface water data for nine parameters (calcium, magnesium, sodium, and potassium, as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-5. Data for other analyzed parameters in this group (e.g., total acidity, and ion balance) can be found in Appendix 9.1B.

The major ion concentrations found in the study area were similar to concentrations reported by the USGS from the Lake Clark area (Brabets and Riehle, 2003; Brabets, 2002); however, a greater range of values was found in this study.

All of the major ions were detected in all samples, except fluoride (48 percent FOD) and alkalinity (99.6 percent FOD). Calcium and sodium were detected at the highest mean concentrations in this group of parameters; fluoride had a mean concentration an order of magnitude lower than the other major ions (Table 9.1-5).

The average CV for the major ions was 0.39, indicating relatively low variability in concentrations of these parameters relative to trace elements (overall CV of 1.6).

Calcium (Total). Total calcium was detected at a mean concentration of 5.03 mg/L, which was essentially the same as dissolved calcium. The CV for total calcium was 0.35.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 5.09 mg/L, the highest concentrations of all major ions. Calcium was detected above the reported detection limits (MRLs) in all samples. The CV for dissolved calcium was 0.35.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 1.31 mg/L, which is essentially the same as for dissolved magnesium. The CV for total magnesium was 0.45, indicating concentrations were generally similar across locations and sampling dates.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 1.32 mg/L, which is the third most abundant ion for streams in this drainage. The CV for dissolved magnesium was 0.44.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.35 mg/L. The CV for total sodium was 0.23.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.38 mg/L and is the second most abundant ion in the NFK river samples. The CV for dissolved sodium was 0.23.

Potassium (Total). Total potassium was detected in all samples at a mean concentration of 0.39 mg/L, making potassium one of the most abundant elements present in river samples for this drainage. The CV for total potassium was 0.40.

Potassium (Dissolved). Dissolved potassium was detected in all samples at a mean concentration of 0.41 mg/L, making it one of the more abundant dissolved metals for river samples in the drainage. The CV for dissolved potassium was 0.39.

Alkalinity, Total. The FOD for total alkalinity was 99.6 percent. Total alkalinity was detected at a mean concentration of 20.5 mg/L. The CV for total alkalinity was 0.38.

Sulfate. Sulfate was detected in all samples from the North Fork Koktuli River, at a mean concentration of 2.26 mg/L. The CV for sulfate was 0.56. Sulfate concentrations are similar to sodium concentrations for river samples in this drainage.

Chloride. Chloride was detected in all surface water samples in the North Fork Koktuli River at a mean concentration of 0.66 mg/L. The CV for chloride was 0.25, implying a small range of concentrations across North Fork Koktuli river samples as shown on Table 9.1-5.

Fluoride. The FOD for fluoride was 48 percent. Fluoride was detected at a mean concentration of 0.03 mg/L, which is below the MDL for fluoride. Most detects were below the MRLMRL, indicating the mean is a function of detection limits and estimated values. Concentrations of fluoride are about $1/20^{th}$ the concentrations of chloride found in these samples.

Hardness as $CaCO_3$ (Filtered). Hardness as calcium carbonate ($CaCO_3$; [filtered]) was detected in all 30 samples at a mean concentration of 14.4 mg/L. The CV for hardness as $CaCO_3$ (filtered) was 0.36. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected in all 233 samples at a mean concentration of 17.9 mg/L, which is slightly higher than the mean for filtered hardness. The CV for hardness as $CaCO_3$ (not filtered) was 0.37.

Nutrients

Data for three parameters (nitrogen, total ammonia [as N]; total nitrate+nitrite [as N]; and phosphorus) are discussed in this section and summarized in Table 9.1-5. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1B. The overall coefficient

of variation (CV) for this group was 1.50, which is higher than that of the South Fork Koktuli River and Upper Talarik Creek, and 50 percent higher than that of Kaskanak Creek samples.

Nitrogen, Total Ammonia (as N). The FOD for nitrogen, total ammonia (as N) was 21 percent. Most samples were detected at concentrations below the MRL and thus represent estimated values. As a result, the calculated mean concentration of 0.032 mg/L is at the lower end of the range of MDLs. The CV for total ammonia (as N) was 0.88.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 77 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.2 mg/L. The CV for total nitrate+nitrite (as N) was 2.22, indicating relatively high variability for this parameter. Total nitrate+nitrite (as N) is dominated by nitrate, as shown by the relative abundance of the two components of the mixture.

Phosphorus. The FOD for phosphorus was 80 percent. Phosphorus was detected at a mean concentration of 0.024 mg/L, which is within the range of MRLs and MDLs. The mean is, in part, a function of detection limits and estimated values. The CV for phosphorus was 1.39.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any North Fork Koktuli River water samples.

Total Trace Elements

Data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-5 and discussed below. Barium and iron, were detected in all samples, while cadmium was detected in the fewest (9 percent) number of samples. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1B.

Iron was detected at the highest mean concentration (0.22 mg/L) across all trace elements. All other total trace elements were present at substantially lower concentrations, ranging from 0.039 mg/L for aluminum to 0.000014 mg/L for cadmium.

The overall CV for total trace elements in North Fork Koktuli River surface water samples was 1.55. The majority of the variability represents seasonal differences in concentrations, as further discussed in subsequent subsections.

Aluminum. The FOD for total aluminum was 95 percent. Aluminum was detected at a mean concentration of 0.039 mg/L. The CV for total aluminum was 1.38. The majority of North Fork Koktuli River samples were above the limits of detection.

Barium. Total barium was detected in all samples at a mean concentration of 0.0034 mg/L. The CV for total barium was 0.38, representing little variability in barium concentrations across sample locations and dates. Barium was primarily detected above MRLs.

Iron. Total iron was detected in all samples at a mean concentration of 0.22 mg/L. Iron is one of the most abundant trace elements in soil, as is apparent from the mean and majority of values, which are above both MDLs and MRLs. The CV for total iron was 0.73.

Copper. Total copper was detected in all but one sample at a mean concentration of 0.00042 mg/L, which is within the range of MRLs and at the upper range of MDLs. Copper concentrations are generally near the limits of detection for river samples in this drainage. The CV for total copper was 0.98.

Zinc. The FOD for dissolved zinc was 68 percent. Zinc was detected at a mean concentration of 0.0026 mg/L, which is within the range of MDLs for this metal. The CV for dissolved zinc was 5.0, indicating zinc concentrations are among the more variable of the trace elements.

Lead. The FOD for total lead was 30 percent. Lead was detected at a mean concentration of 0.00022 mg/L, which is above the MDL and MRL range. The CV for total lead was 4.12, indicating lead concentrations are among the more variable of the trace elements.

Cadmium. The FOD for total cadmium was 9 percent. Cadmium was detected at a mean concentration of 0.000014 mg/L. The mean value is below the range of MRLs, indicating that detected concentrations were largely estimated values. The CV for total cadmium was 1.09.

Arsenic. The FOD for total arsenic was 33 percent. Arsenic was detected at a mean concentration of 0.00023 mg/L. The CV for total arsenic was 0.63. The majority of samples were below the MRL, indicating the mean is largely a function of detection limits and estimated values.

Nickel. The FOD for total nickel was 68 percent. Nickel was detected at a mean concentration of 0.00022 mg/L, which is just above the range of MRLs, indicating many of the detected nickel concentrations are estimated values. The CV for total nickel was 1.15.

Molybdenum. The FOD for total molybdenum was 85 percent. Molybdenum was detected at a mean concentration of 0.00017 mg/L, which is within the range of MRLs and MDLs for this element. Therefore, detected molybdenum concentrations represent a mixture of estimated and measured concentrations. The CV for total molybdenum was 0.59.

Manganese. The FOD for total manganese was 99.6 percent. Manganese was detected at a mean concentration of 0.014 mg/L, which is above both MRLs and MDLs. The CV for total manganese was 1.04.

Dissolved Trace Elements

Data for aluminum, barium, iron, cadmium, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-5 and discussed below. Data for the other analyzed trace elements are presented in Appendix 9.1B. All dissolved trace elements were detected in surface water samples collected from the North Fork Koktuli River system above detection limits. Two dissolved trace elements (barium and manganese) were detected above detection limits in all surface water samples; cadmium was detected in the fewest number of samples (6 percent FOD).

In general, the mean concentrations of dissolved elements were lower than total elements. Dissolved iron had the highest mean concentration (0.11 mg/L); all others were at least an order of magnitude lower. Dissolved aluminum and manganese were the only other elements detected at mean concentrations of at least 0.01 mg/L; the mean concentrations of the remaining dissolved elements were at least one order of magnitude lower.

The overall CV for dissolved trace elements was 1.82, and the data displayed similar variability as total trace elements, although the CV for lead (11.4) is quite high. Without the extremely high CV for lead included, the overall CV for dissolved trace elements drops to 0.86, which is substantially less than that for total trace elements.

Aluminum. The FOD for dissolved aluminum was 88 percent. Aluminum was detected at a mean concentration of 0.013 mg/L, about one-third the mean concentration of total aluminum. The mean concentration is within the range of MRLs and MDLs, and the maximum concentration is below the maximum MRL. Therefore, many of the values are estimated concentrations. The CV for dissolved aluminum was 0.82, which is lower than that for total aluminum for these same samples.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0031 mg/L, which is above the range of MRLs and MDLs. The CV for dissolved barium was 0.35, essentially the same as that for total barium.

Iron. The FOD for dissolved iron was 97 percent. Iron was detected at a mean concentration of 0.11 mg/L, which is well above the MRLs and MDLs. Iron represents the most abundant of the dissolved metals. The CV for dissolved iron was 0.68.

Copper. The FOD for dissolved copper was 98 percent. Copper was detected at a mean concentration of 0.00039 mg/L, which is within the range of MRLs for this metal. This indicates that many of the detected values for dissolved copper represent estimated concentrations. The CV for dissolved copper was 0.84.

Zinc. The FOD for dissolved zinc was 79 percent. Zinc was detected at a mean concentration of 0.0018 mg/L, which is within the range of MRLs for this metal. The CV for dissolved zinc was 0.64.

Lead. The FOD for dissolved lead was 22 percent. Lead was detected at a mean concentration of 0.00039 mg/L, which is within the range of MRLs. The CV for dissolved lead was 11.4, by far the highest variability of any of the metals for river samples in this drainage. The CV is largely driven by the maximum detected concentration of 0.082 mg/L, which is two orders of magnitude greater than the mean. This dataset is skewed when comparing the median to the mean; the median is an order of magnitude lower than the mean (Table 9.1-5).

Cadmium. The FOD for dissolved cadmium was 6 percent. Cadmium was detected at a mean concentration of 0.000012 mg/L. The CV for dissolved cadmium was 0.61. The mean concentration is below the MRLs, indicating the mean is a function of detection limits and estimated concentrations.

Arsenic. The FOD for dissolved arsenic was 24 percent. Arsenic was detected at a mean concentration of 0.0002 mg/L. The mean concentration is within the range of MRLs and MDLs, and the maximum concentration is below the maximum MRL. Therefore, many of the values are estimated concentrations. The CV for dissolved arsenic was 0.57.

Nickel. The FOD for dissolved nickel was 87 percent. Nickel was detected at a mean concentration of 0.003 mg/L, which is within the range of MRLs. Many of the detected nickel concentrations are estimated values. The CV for dissolved nickel was 1.14.

Molybdenum. The FOD for dissolved molybdenum was 83 percent. Molybdenum was detected at a mean concentration of 0.00019 mg/L, which is within the range of MRLs and MDLs for this metal. Therefore, the mean concentration is driven by the detection limits and estimated values. The CV for dissolved molybdenum was 1.22.

Manganese. Dissolved manganese was present in all samples at a mean concentration of 0.01 mg/L, which is above the range of MRLs for this metal. Most of the detected concentrations were above detection limits for manganese. The CV for dissolved manganese was 1.67.

Cyanides

Total Cyanide. Total cyanide was detected in only 17 (7 percent) surface water samples in the North Fork Koktuli River. Total cyanide was detected at a mean concentration of 0.0019 mg/L. The CV for cyanide was 5.03, indicating wide variability of concentrations across samples. The maximum detected concentration of 0.15 mg/L was two orders of magnitude greater than the lowest detected concentration (0.0015 mg/L).

WAD Cyanide. The FOD for weak acid dissociable (WAD) cyanide was 13 percent. WAD cyanide was detected at a mean concentration of 0.0015 mg/L. The CV for WAD cyanide was 0.91, which is much lower than that for total cyanide. The maximum detected WAD cyanide concentration of 0.012 mg/L is an order of magnitude less than the highest total cyanide concentration for North Fork Koktuli River samples.

Organic Compounds

In 2004, 2005, and 2007, a subset of surface water samples from North Fork Koktuli River was analyzed for organic compounds (DRO, GRO, and RRO), VOCs, SVOCs, PCBs, and pesticides. These compounds were not expected to be detected due to anthropogenic sources because of the remote, undeveloped nature of the area. Six samples were collected and analyzed to provide confirmation of this assumption. As shown in Appendix 9.1B, none of these organic compounds were detected in surface water samples from North Fork Koktuli River.

Dissolved Organic Carbon. The FOD for dissolved organic carbon was 99 percent. Dissolved organic carbon was detected at a mean concentration of 1.5 mg/L. The CV for organic carbon was 0.51, with a range of values between 0.50 and 4.55 mg/L.

Comparison with Water Quality Criteria

Trace element concentrations were compared against Alaska Department of Environmental Conservation (ADEC) water quality criteria for the protection of human health and aquatic life (ADEC, 2009). The most stringent available values for human and ecological receptors were used for the comparison. Generally, human health criteria represent total (unfiltered) concentrations, and aquatic life criteria represent dissolved elements concentrations. Therefore, total elements data were compared to human health criteria, and both total and dissolved elements data were compared to aquatic life criteria. Only WAD cyanide data were compared to the single cyanide criterion, which is based on free cyanide. There is no approved analytical method for free cyanide, as results have been shown to be unreliable. Instead, measurement of WAD cyanide is typically used to approximate free cyanide

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates.

A summary of the comparison of detected concentrations and criteria is presented in Table 9.1-10. Concentrations of most constituents met criteria. Concentrations were outside the most stringent criteria in at least one sample for the following constituents:

- pH was outside the criteria range in 79 of 240 samples.
- DO was below the minimum criteria in 19 of 234 samples.
- Alkalinity was below the minimum criteria in 89 of 240 samples.
- WAD cyanide was above the maximum criteria in 6 of 232 samples.

The pH was out of the most stringent criteria range at seven locations. The locations with the most samples with concentrations out of the most stringent criteria range were NK119A (25 of 79) and NK100B (17 of 79). In all cases, pH was below the most stringent criteria range, indicating locations with acidic water occur in the North Fork Koktuli River throughout the year. Alkalinity was below the most stringent minimum value in many samples from multiple locations. The samples where WAD cyanide concentrations were naturally above the most stringent maximum criteria were at locations NK100A, NK100A1, and NK100C.

Seven trace elements had concentrations above the most stringent maximum criteria in at least one sample:

- Aluminum (total: 14 of 233 samples).
- Cadmium (total: 6 of 233 samples; dissolved: 1 of 230 samples).
- Copper (total: 5 of 232 samples; dissolved: 3 of 164 samples).
- Iron (total: 1 of 232 samples).
- Lead (total: 34 of 232 samples; dissolved: 14 of 192 samples).
- Manganese (total: 6 of 232 samples).
- Zinc (total: 2 of 231 samples).

The majority of the 14 total aluminum samples with concentrations above the most stringent maximum criteria were from the sampling stations located furthest downstream (stations NK100A, NK100B, and NK100C). The majority of these events occurred during the months of April and May. This may be related to snowmelt that typically occurs at this time of year. This pattern is not seen in the lead data. The highest single lead concentration (400 times above the most stringent maximum criteria) occurred at the station located furthest downstream (station NK100A) in September. Only one other lead concentration was more than 10 times the most stringent criteria (a May sample at station NK100B).

The other five trace elements had a few concentrations above the most stringent maximum criteria (less than 3 percent of samples), which is not unexpected given the large number of samples collected.

Spatial and Temporal Trend Analysis

Spatial trend analysis was conducted in three ways. First, regression analysis was conducted to identify any notable trends in total constituent concentrations from upstream to downstream for parameters routinely detected above MRLs. The purpose of this analysis was to determine if concentrations of specific constituents into the drainage along the course of the river has effects on concentrations at downstream sampling locations.

Second, correlation analysis was conducted to compare streamflow and chemical concentrations. This analysis was prepared to compare the influence of streamflow on the concentration of constituents in the main stem of the North Fork Koktuli River.

Finally, stacked bar graphs were also prepared, showing median concentrations by location for each month. These graphs were prepared to determine whether concentrations in the river system along the course of the river flow affects concentrations at downstream sampling locations.

For the first two analyses, median concentrations for each sample location were ordered from upstream to downstream (Table 9.1-11). A linear regression analysis was performed for parameters routinely detected above detection limits. Linear regression coefficients (R^2 values) and probability (p-values) from the Mann-Whitney U-Test, a non-parametric version of the two-sample *t*-test, were evaluated to identify any significant trends. Spatial regression results are presented in Table 9.1-12, and the significant results are shown graphically in Appendix 9.1E.

Based on evaluation of the regression analysis of concentrations as a function of downstream distance, a significant positive trend (increasing concentrations or values with downstream distance) was apparent from the regression analysis for pH.

Significant negative trends (decreasing concentrations or values with downstream distance) were apparent from the regression analysis for the following constituents:

- Nickel
- Potassium
- TDS

Streamflow effects on concentrations were evaluated by plotting both median analyte concentrations and median daily streamflow measurements (in cubic feet per second) in log scale from upstream to downstream on the same graph for parameters routinely detected above detection limits. These graphs are presented in Figures 9.1-7 through 9.1-25.

A positive correlative trend is apparent between concentrations and streamflow for sodium (Figure 9.1-10), chloride (Figure 9.1-14), and molybdenum (Figure 9.1-24), and inverse trends are more apparent for TDS (Figure 9.1-7), TSS (Figure 9.1-9), potassium (Figure 9.1-11), alkalinity (Figure 9.1-12), hardness (Figure 9.1-15), iron (Figure 9.1-18), and nickel (Figure 9.1-23). This indicates concentration is a function of streamflow for some constituents.

High flow can lead to additional mobilization of constituents from the sediment (i.e., scouring) during both snowmelt in the spring and heavy rains in the fall, which can introduce additional constituents into the downstream locations, particularly for water-soluble ions like sodium and chloride. For parameters that indicate the opposite trend, water with low concentrations of these constituents (e.g., TSS) may be entering the main stem of the river from tributaries, resulting in lower concentrations as the water is mixed in the main stem.

The correlative parameters (Figures 9.1-7 through 9.1-25) and stacked bar graphs (Figures 9.1-26 through 9.1-47) are discussed below by parameter group. Only graphs for parameters consistently detected above detection limits in at least one location and month, and/or with significant differences identified, are presented and discussed in the following text. In general, the absence of a bar for a station means the location wasn't sampled often. In fewer cases, the absence of a bar for a station indicates the lack of detections at that location for the constituent. Note that these graphs are not meant to imply cumulative values, but are intended to be used solely to compare concentrations at different locations across months.

Temporal line graphs were prepared to assess seasonal tendencies for total concentrations of each analyte routinely detected above MRLs at each sampling location (Appendix 9.1F). For each chemical-specific graph, each line represents a different sampling location, with month across the x-axis and median concentration on the y-axis. These graphs are presented in Appendix 9.1F, and key highlights are discussed below. Note that the Y-axis is a linear scale, and some values are presented in scientific notation (i.e., 2.0E-2 is 0.01 and 5.0E1 is 50).

Field and Physical Parameters

Some seasonal patterns are apparent in the temporal line graphs. The majority of sampling locations had the lowest median concentrations in April or May. All of these results are consistent with the influx of eroded material from increased flows during snowmelt in the spring months and precipitation events in the fall months.

Total Dissolved Solids. The median concentration for TDS was 37.5 mg/L but was shown to have significantly different (p-value less than 0.05) concentrations upstream and downstream. This parameter was generally detected at statistically higher concentrations upstream. Median concentrations of TDS decline steadily between locations NK100C and NK100A1 (Figure 9.1-7). Median concentrations of TDS then increase slightly at the furthest downstream location (NK100A).

TDS concentrations were generally similar throughout the year at most stations, although slightly lower during the drier months (e.g., June) at some stations. Exceptions to these trends include stations NK199B and NK100A, which were lowest in January and May, and station NK119B, which was lowest in February and November. TDS exhibited a peak concentration at station NK100C in February (Figure 9.1-26).

pH (Field). The median pH was 6.77, and pH was higher in downstream locations (Figure 9.1-8). The pH drops slightly at station NK100B, and then rises above the median at the two furthest downstream locations (NK100A1 and NK100A). In general, locations NK119A and NK1119B were associated with the lowest median pH values (Figure 9.1-27).

The pH values tended to be more basic in spring and fall. For example, the pH values were slightly more basic in August at most locations, particularly at station NK100C (Figure 9.1-27). The lowest pH was associated with station NK100A1 in January.

Total Suspended Solids. The median concentration for TSS was 0.82 mg/L. This parameter was generally detected at higher concentrations upstream. Median concentrations of TSS decline steadily between locations NK100C and NK100A1 (Figure 9.1-9). Median concentrations of TSS then increase slightly at the furthest downstream location (NK100A).

April and November had the two highest median TSS concentrations (both at station NK100A; Figure 9.1-28). May had the highest concentrations at locations NK100B and NK100C, both located downstream of station NK100A. This likely represents additional suspended particulates from eroded material from the increased flows during snowmelt at this time (and from rainfall in the November peak). Most other months are uniformly low for median concentrations of TSS.

Major Ions

Many of the major ions demonstrated relatively high median concentrations at location NK100C. Given the remoteness of this location relative to the deposit area, it appears the higher median values of most ions at this location are a local phenomenon unrelated to the ore deposit. Individual ions are discussed below.

Sodium. Sodium was generally detected at higher concentrations downstream. Median concentrations of sodium decline steadily between locations NK100C and NK100B, then rise at stations NK100A1 and NK100A. Concentrations of sodium were lowest at location NK100B, and generally consistent in concentrations at other locations (Figure 9.1-10).

The graph for sodium (Figure 9.1-29) indicates consistent concentrations are present at most locations and months for this analyte. The lowest concentrations of sodium across all locations occurred in May and were generally highest in March. The temporal line graph (Appendix E) shows a seasonal pattern that is not statistically significant for median concentrations of sodium.

Potassium. Potassium had a substantially different concentration upstream and downstream. Potassium was detected at statistically higher concentrations upstream (Figure 9.1-11). Potassium concentrations steadily decline as streamflow increases. Potassium had different concentrations at different sampling stations and was generally highest at station NK100C and lowest at station NK119B (Figure 9.1-30).

Potassium concentrations were lowest at most stations in June (Figure 9.1-30) and were highest in the spring. This is particularly evident at location NK119B, with a concentration in March near twice the next highest monthly median concentration.

Alkalinity, Total. The median concentration for total alkalinity was 22 mg/L. Alkalinity declined in median concentrations as streamflow increased, indicating water with lower alkalinity is added to the system as the river flows downstream (Figure 9.1-12).

Alkalinity concentrations were lowest in the spring months due to influx of eroded material from increased snowmelt, and increased slightly over the winter between September and March (Figure 9.1-

31). The temporal line graph (Appendix E) shows a seasonal pattern that is not statistically significant for median concentrations of total alkalinity.

Sulfate. Sulfate concentrations exhibited no trend with regard to sample location (Figure 9.1-13). Median concentrations of sulfate are lower at the two most-upstream sampling locations (NK100C and NK100B) than at the two most-downstream locations (NK100A1 and NK100A). Concentrations of sulfate were lowest at location NK100B, but generally consistent in concentrations at other locations.

Sulfate concentrations showed little in the way of seasonal patterns. The graph for sulfate (Figure 9.1-32) indicates consistent concentrations are present at most locations and months, with the exception of tributary location NK119B which has consistently detectable levels in all months except February. Concentrations were highest in July through December at tributary location NK119B, located near main stem location NK100C. Sulfate concentrations are uniformly low at location NK119A, which is located upstream from location NK119B in the same tributary. Apparently, sulfate is entering the system along this tributary in the latter half of the year and is then diluted upon reaching the main stem of the North Fork Koktuli River, as evidenced by the generally lower downstream concentrations in the mainstem.

Chloride. Concentrations of chloride were lowest at location NK100B and generally consistent at other locations. Chloride concentrations increased between locations NK100B and NK100A, indicating a general direct relationship with streamflow (Figure 9.1-14).

The graph for chloride (Figure 9.1-33) indicates consistent concentrations are present at most locations and months for this constituent. The majority of sampling locations peaked in median concentrations in April for chloride, with a second, smaller peak in September. These correspond to snowmelt and rainfall events. The temporal line graph (Appendix E) shows a seasonal pattern that is not statistically significant.

Fluoride. All of the monthly medians for fluoride were below MRLs. Therefore, no streamflow graph was prepared for fluoride.

The median concentrations for fluoride are at or below the MRL (except station NK119B in September) because of the inclusion of estimated concentrations below the detection limit in the datasets. Based on the stacked bar graph, the concentrations vary across months (Figure 9.1-34). Fluoride has the highest concentration at most stations during September. Tributary location NK119B has increasing concentrations between March and September.

Hardness as $CaCO_3$ (Not Filtered). The median concentration for hardness (not filtered) was 18.1 mg/L. Hardness (not filtered) declined in median concentrations as streamflow increased, indicating water with lower hardness is added to the system as the river flows downstream (Figure 9.1-15).

Hardness was generally lowest in the spring during snowmelt and increased through fall and winter (Figure 9.1-35). The majority of sampling locations had the lowest median concentrations in April or May. This result is consistent with the influx of eroded particles from increased snowmelt during these months. A much smaller dip in concentrations occurs in September due to fall rains. The temporal line graph (Appendix E) shows a seasonal pattern that is not statistically significant.

Nutrients

Total Nitrate+Nitrite (as N). The median concentration for total nitrate+nitrite (as N) was 0.086 mg/L. Concentrations of total nitrate+nitrite (as N) were generally similar across sampling locations and showed no correlation with streamflow (Figure 9.1-16). Total nitrate+nitrite (as N) is detectable in the system in all months with the highest concentrations in July (Figure 9.1-36). The July concentrations are highest primarily in one tributary, which includes, stations NK119A and NK119B. This tributary provides nitrate and nitrite into the main stem of the River, as evidenced by the higher concentration at station NK100C, located at the confluence of the tributary and the main stem of the North Fork Koktuli River, than at downstream station NK100B.

Phosphorus. Phosphorus concentrations decreased between stations NK100C and NK100A, indicating a general inverse relationship with streamflow (Figure 9.1-17).

Phosphorus exhibited peak median concentrations in summer, particularly at stations NK100A and NK119B (Figure 9.1-37). The summer concentrations are relatively evenly distributed across other locations. Median concentrations of phosphorus were mostly below MRLs, indicating the majority of data points represent estimated concentrations.

Total Orthophosphate (as P). This constituent was not detected in any sample. Therefore, graphs were not prepared for total orthophosphate (as P). No temporal line graph is presented because total orthophosphate (as P) was not detected in any sample.

Trace Elements

The temporal line graphs in Appendix 9.1F show that seasonal patterns are apparent. Results are discussed below.

Iron. A generally negative correlative trend is apparent between concentrations and water flow for iron (Figure 9.1-18). Iron concentrations decline steadily from station NK100C to station NK100A1, and then increase slightly at station NK100A.

The majority of sampling locations peaked in median iron concentrations in May, but the highest iron peak was in February at location NK100C. The iron concentrations were consistently highest at this location across all months. This is different from the other locations, where the strongest peak was in the spring and a secondary peak was in the fall (Figure 9.1-38). The temporal line graph (Appendix E) shows a seasonal pattern that is not statistically significant.

Copper. A generally negative correlative trend is apparent between concentrations and water flow for copper (Figure 9.1-19). However, the increase in copper concentration at the most downstream location, NK100A, weakens this statistical relationship.

Copper median concentrations peak in April and May at several locations; the highest concentration is in May at station NK100A1 while the next highest concentration is in April at station NK100A (Figure 9.1-39). Most locations have a second, much smaller peak in September (Appendix E). These correspond to snowmelt and rainfall events.

Zinc. A negative correlative, but weak, trend is apparent between concentrations and water flow for zinc (Figure 9.1-20).

Zinc median concentrations peak at station NK119A in February, but most locations have highest concentrations in the spring or fall months (Figure 9.1-40; Appendix E).

Lead. No correlation is apparent between lead concentrations and streamflow (Figure 9.1-21). No clear temporal pattern is evident for lead. Concentrations at stations NK100B and NK119A peak in winter and spring, respectively, while concentrations at station NK100A peak in the fall. However, higher concentrations of lead occur at single locations during the months of February (station NK119A), March (station NK100B), and May (station NK100B; Figure 9.1-41). Tributary location NK119A had a notably high concentration of lead in February; interestingly, the main stem sampling location, station NK100B, which is located downstream of station NK119A, had an increase in concentration the following month. It is possible the increase in lead concentrations at station NK100B is a result of the higher concentration flowing into the main stem from tributary station NK119A.

Cadmium. No trend is apparent for cadmium as a function of streamflow (Figure 9.1-22). Half of the medians are below the MRL, indicating estimated concentrations.

The highest concentrations of cadmium occur during the months of April and May, with medians above reporting limits for multiple locations in these months, particularly at locations NK100A1 and NK100D (Figure 9.1-42). Cadmium median concentrations are mostly below MRLs.

Arsenic. All of the monthly medians for arsenic were below MRLs. Therefore, no streamflow graph was prepared for arsenic.

Arsenic concentrations are below the MRL at most locations. Concentrations of arsenic were fairly consistent across most sample locations throughout the year (Figure 9.1-43). Exceptions include sample location NK100A1, which had detectable arsenic concentrations only during the month of May, and sample location NK100C, which was the only station with detectable median concentrations in the months of December and January. Tributary sample locations NK119A and NK119B had variable median concentrations across months, with most months below detection limits. The highest median concentrations occur at station NK100C in June through September.

Nickel. A negative trend is apparent between concentrations and water flow for nickel. Nickel had a significantly different concentration upstream and downstream. Nickel was detected at statistically higher concentrations upstream (Figure 9.1-23).

Nickel median concentrations were generally low and consistent across sample locations and months, with the exception of station NK119A in February. This tributary had a median concentration in February that was fivefold higher than any other month or location (Figure 9.1-44).

The temporal line graph (Appendix E) shows a clear peak for nickel at station NK119A in February. Smaller peaks are seen at stations NK100A1 and NK119B in May and September.

Molybdenum. Molybdenum concentrations are correlated with streamflow; concentrations are higher downstream than in upstream locations (Figure 9.1-24).

The concentrations of molybdenum were fairly consistent across sample locations throughout the year (Figure 9.1-45). Several locations exhibited small fluctuations, but no noticeable trends are apparent. Molybdenum has its highest median concentrations at station NK100A1 in May.

Cyanides

Total Cyanide. Total cyanide was detected at median concentrations below MRLs. Therefore, no streamflow graph was prepared. **Total** cyanide showed no trend and was not routinely detected in North Fork Koktuli River samples.

A single peak was apparent for total cyanide in February at station NK100C (Figure 9.1-46); all other months had median concentrations below MRLs. Based on the temporal line graphs (Appendix E), the median concentration was approximately 3 times lower at this location in July, and reached the low levels observed for all other locations and months by August. Based on these observations, cyanide appears to be naturally produced at this location in the winter but does not appear to be a widespread phenomenon.

WAD Cyanide. WAD cyanide was detected at median concentrations below MRLs in all locations except NK100A1; no trend was apparent with streamflow (Figure 9.1-25).

WAD cyanide followed a similar pattern as that of total cyanide, but the concentrations at station NK100C peaked in June rather than February. Median concentrations of WAD cyanide were reported above MRLs more often than total cyanide. WAD cyanide was detected in eight months, February to June, August, September, and December (Figure 9.1-47). Contribution into the system in March (station NK100A) and June (station NK100C) were each limited to a single location, but other locations contributed in other months. No detected concentrations at station NK100C were identified in February, March, or May. Other locations had detectable median concentrations in two to five months. These results imply that cyanide is released sporadically into the system at different locations in different months, possibly because of the growth of cyanogenic bacteria at different times in different locations. Perhaps later in the season when the temperature increases, more of the cyanide detected in February becomes weak acid dissociable, leading to this later seasonal peak at station NK100C. This is supported by results of plant and soil analyses, as discussed in Chapter 10 of the EBD.

9.1.8.2. Results and Discussion: South Fork Koktuli River

This section presents the findings of the surface water quality study in the South Fork Koktuli River drainage in the mine study area (Figure 9.1-1). Surface water samples and measurement of physical and chemical parameters were obtained from the river and its tributaries to assess the spatial and temporal variability of field and physical parameters, major ions, nutrients, total and dissolved trace elements, and cyanides in the project study area. The analysis was conducted using data acquired during the 5-year period from 2004 to 2008.

The South Fork Koktuli River study area encompasses approximately 25 miles of the main stem of the river originating from the deposit area and ending at the confluence with North Fork Koktuli River. It includes seven tributaries. Sampling locations SK134, SK136A, and SK136B are within the general pit location.

As shown in Table 9.1-6, 612 surface water samples were collected from 18 sampling locations in the South Fork Koktuli River and its tributaries between 2004 and 2008. The number of sample results differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, cyanides, and organic compounds.

Field and Physical Parameters

Eight field and physical parameters were measured in South Fork Koktuli River surface water samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-6. Most of these parameters were analyzed in 601 surface water samples.

These parameters generally showed similar variability to major ions and less variability than trace elements in this system. The overall CV across all field and physical parameters was 0.87.

Total Dissolved Solids. TDS was detected at a mean concentration of 44 mg/L (Table 9.1-6). The CV for TDS was 0.41, indicating relatively low variability in this parameter.

pH (Field). The mean field pH value for surface water samples collected from the South Fork Koktuli River and its tributaries was 7.0 (pH units), which indicates the water in the South Fork Koktuli River is neutral. The very low CV of 0.045 indicates pH is stable across the drainage.

Dissolved Oxygen. DO was detected in all samples at a mean concentration of 10.2 mg/L, which indicates the surface water is well aerated and contains substantial DO. The CV for DO was 0.21, which represents low variability of DO concentrations.

Water Temperature. The mean water temperature was 4.77^{o}C, and the CV for water temperature was 1.02. The CV represents seasonal differences in water temperature, which can be as high as 23.5^{o}C in later summer and as low as -0.2^{o}C in winter.

Specific Conductivity (Field). The mean concentration for specific conductivity was 55.5 uS/cm, which is below the range of MRLs. This indicates the mean is based on the detection limits and estimated values. The CV for specific conductivity was 0.44.

Turbidity. The mean concentration for turbidity was 1.85 NTU. The CV for turbidity was 1.59, indicating greater variability in this parameter than for most others in this group.

Total Suspended Solids. TSS was detected in 90 percent of samples and had a mean concentration of 2.21 mg/L, which is within the range of MRLs and MDLs for this parameter. The CV for TSS was 2.13, indicating relatively high variability.

Oxidation Reduction Potential. ORP was detected in all but one sample at a mean concentration of 126 mV and ranged from -259 mV to 875 mV. The CV for ORP was 0.80.

Major Ions

South Fork Koktuli River surface water data for nine parameters (calcium, magnesium, sodium, and potassium [total and dissolved], as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-6. Data for other analyzed parameters in this group (e.g., total acidity, and ion balance) can be found in Appendix 9.1B.

All parameters in this group, except alkalinity and fluoride, were detected in all samples. The FOD for alkalinity was 99.7% and fluoride was 60 percent. Sulfate (8.78 mg/L) and calcium (6.36 mg/L) were detected at the highest mean concentrations of the individual ions, and fluoride was detected at the lowest mean concentration (0.05 mg/L).

The CV of 0.46 for major ions is low relative to other groups in this drainage and consistent with the CVs of 0.39 and 0.48 in the North Fork and Upper Talarik Creek samples, respectively.

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 6.36 mg/L. Total calcium is the second most abundant major ion in the South Fork Koktuli River samples, second only to total sulfate. The CV for total calcium was 0.43, indicating generally consistent concentrations across samples.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 6.34 mg/L. Calcium is also the second most abundant dissolved metal. The CV for dissolved calcium was 0.42, indicating low variability in concentrations.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 1.41 mg/L. The CV for total magnesium was 0.56, reflecting low variability in concentrations. Dissolved and total magnesium values were virtually identical across samples.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 1.41 mg/L. The CV for dissolved magnesium was 0.56.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.35 mg/L, which is the third most abundant ion in South Fork Koktuli River samples. The CV for total sodium was 0.38. Dissolved and total sodium values were virtually identical across samples.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.35 mg/L, which is identical to the total sodium mean concentration. The CV for dissolved sodium was 0.35.

Potassium (Total). Total potassium was detected in all samples at a mean concentration of 0.38 mg/L. The CV for total potassium was 0.47.

Potassium (Dissolved). Dissolved potassium was detected in all samples at a mean concentration of 0.38 mg/L. The CV for dissolved potassium was 0.46.

Alkalinity, Total. The FOD for total alkalinity, measured as calcium carbonate, was 99.7 percent. The mean total alkalinity concentration is 17.4 mg/L. The range of alkalinity measured in the study area is similar to the range reported by the USGS from the Lake Clark area (Brabets and Riehle, 2003; Brabets, 2002) and other Alaskan streams (Scannel and Ott, 1994). The CV for total alkalinity was 0.43.

Sulfate. Sulfate was detected in all samples at a mean concentration of 8.78 mg/L, making it the most abundant of the anions in river samples for this drainage. The CV for sulfate was 0.87.

Chloride. Chloride was detected in all samples at a mean concentration of 0.69 mg/L. The CV for chloride was 0.26.

Fluoride. The FOD for fluoride was 60 percent. Fluoride was detected at a mean concentration of 0.05 mg/L, which is below the range of MRLs. This indicates the mean is largely a function of detection limits and estimated values. The CV for fluoride was 0.35.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected at a mean concentration of 21.6 mg/L, which is only slightly higher than the mean for filtered hardness. The CV for hardness as $CaCO_3$ (not filtered) was 0.44. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria. Higher concentrations of hardness are generally associated with lower element toxicity (Cockerham and Shane, 1994).

Hardness as $CaCO_3$ (Filtered). Hardness as $CaCO_3$ (filtered) was detected at a mean concentration of 19.6 mg/L in the 70 samples analyzed for this parameter. The CV for hardness as $CaCO_3$ (filtered) was 0.47. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-6. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1B.

Nutrients were not detected in all samples. Total nitrate+nitrite (as N) was detected in 84 percent of surface water samples, whereas nitrogen, total ammonia (as N) was detected in only 20 percent of samples.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.51 (total ammonia as N) to 1.77 (total nitrate+nitrite [as N]). The CV for all nutrients was 1.29.

Total Ammonia (as N). The FOD for total ammonia (as N) was 20 percent (Table 9.1-6). Total ammonia (as N) was detected at a mean concentration of 0.054 mg/L, which is within the range of MRLs and indicates the mean is largely a function of detection limits and estimated values. The maximum detected concentration was 0.40 mg/L. The CV for total ammonia (as N) was 0.51.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 84 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.23 mg/L. Because nitrite was essentially all non-detect (Appendix 9.1B), this parameter is comprised primarily of nitrate. The CV for total nitrate+nitrite (as N) was 1.77, which is the greatest variability across the nutrients for river samples in this drainage.

Phosphorus. The FOD for phosphorus was 81 percent. Phosphorus was detected at a mean concentration of 0.023 mg/L, which is within the range of MRLs and MDLs. The mean is, in part, a function of detection limits and estimated values. The CV for phosphorus was 1.58.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any South Fork Koktuli River water samples.

Total Trace Elements

Data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-6 and discussed below. Total trace elements were analyzed in approximately 600 samples. Barium was the only total trace element detected in all samples, and cadmium was detected in the fewest (16 percent) samples. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1B.

As indicated by the CVs, the variability of total trace elements was high relative to other constituents, with an overall CV of 1.29. The highest CV was for lead (3.99) and the lowest CV was for barium (0.52).

Aluminum. The FOD for total aluminum was 96 percent. Aluminum was detected at a mean concentration of 0.05 mg/L, which is above the range of MRLs and MDLs, and second highest among the trace elements. The CV for total aluminum was 1.76, indicating widespread variability in aluminum concentrations in the South Fork Koktuli River.

Barium. Total barium was detected in all samples at a mean concentration of 0.0043 mg/L, which is well above the range of detection limits. The CV for total barium was 0.52, the lowest among this group of trace elements for river samples for this drainage.

Iron. The FOD for total iron was 95 percent. Iron was detected at a mean concentration of 0.30 mg/L, well above the limits of detection. Iron is the most abundant of the trace elements in South Fork Koktuli River water samples. The CV for total iron was 1.0.

Copper. The FOD for total copper was 99 percent. Copper was detected at a mean concentration of 0.0017 mg/L, which is approximately 3 and 5 times higher than in Upper Talarik Creek and North Fork Koktuli River samples, respectively. This is likely due to the presence of the general deposit area in the headwaters of the South Fork Koktuli River. The CV for total copper was 1.05, representing the differences in concentrations between samples near the general deposit location and those downstream.

Zinc. The FOD for total zinc was 82 percent. Zinc was detected at a mean concentration of 0.0028 mg/L, which is above the range of MDLs and within the range of MRLs. This indicates the mean is based on both detection limits and estimated values, as well as on detected concentrations. The CV for total zinc was 1.12.

Lead. The FOD for total lead was 32 percent. Lead was detected at a mean concentration of 0.00028 mg/L, which is within the range of MRLs. Therefore, the mean represents both detection limits and detected concentrations. The CV for total lead was 3.99, which is the highest variability of trace elements for river samples in the South Fork Koktuli River.

Cadmium. The FOD for total cadmium was 16 percent. Cadmium was detected at a mean concentration of 0.000015 mg/L, which is within the range of MRLs and MDLs. Therefore, the mean is largely a function of detection limits and estimated values. The CV for total cadmium was 1.37.

Arsenic. The FOD for total arsenic was 34 percent. Arsenic was detected at a mean concentration of 0.00035 mg/L, which is within the range of MRLs and MDLs. Therefore, the mean is largely a function of detection limits and estimated values. The CV for total arsenic was 0.61.

Nickel. The FOD for total nickel was 78 percent. Nickel was detected at a mean concentration of 0.00035 mg/L, which is within the range of MRLs, indicating it is based on both detection limits and estimated values, as well as on detected concentrations. The CV for total nickel was 0.73.

Molybdenum. The FOD for total molybdenum was 97 percent. Molybdenum was detected at a mean concentration of 0.00065 mg/L, which is within the range of MRLs. This indicates it is based on both detection limits and estimated values, as well as on detected concentrations. The CV for total molybdenum was 0.97.

Manganese. The FOD for total manganese was 99 percent. Manganese was detected at a mean concentration of 0.025 mg/L, and is one of the most abundant of the metals in South Fork Koktuli River water samples. The CV for total manganese in South Fork Koktuli River samples was 1.09, essentially the same as in North Fork Koktuli River and Upper Talarik Creek water samples.

Dissolved Trace Elements

Data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-6 and discussed below. Data for the other trace elements are presented in Appendix 9.1B. Dissolved mercury was not analyzed.

All dissolved trace elements were detected in surface water samples collected from the South Fork Koktuli River system above detection limits. Barium and manganese were detected in all surface water samples, while cadmium was detected in only 9 percent of samples.

Iron was detected at the highest mean concentration of the dissolved trace elements (0.12 mg/L) and aluminum was second highest (0.11 mg/L). The remaining dissolved trace elements were considerably below 0.01 mg/L.

As indicated by calculated CVs (overall CV for dissolved trace elements of 0.81), the analytical data for dissolved trace elements displayed lower variability than for total trace elements, with CVs ranging from 0.48 (barium) to 1.14 (manganese).

Aluminum. The FOD for dissolved aluminum was 87 percent. Aluminum was detected at a mean concentration of 0.011 mg/L. Unlike total aluminum, the mean for dissolved aluminum is within the range of MRLs and MDLs. Therefore, the mean is largely a function of detection limits and estimated values. The CV for dissolved aluminum was 0.68.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0041 mg/L, which is above the range of detection limits. The CV for dissolved barium was 0.48.

Iron. The FOD for dissolved iron was 92 percent. Iron was detected at a mean concentration of 0.12 mg/L, and is one of the most abundant metals in South Fork Koktuli River water samples. The CV for dissolved iron was 1.01.

Copper. The FOD for dissolved copper was 99 percent. Copper was detected at a mean concentration of 0.0013 mg/L, which is above the range of detection limits. The CV for dissolved copper was 0.88. Copper was present at higher concentrations near the general deposit area than at sample locations downstream.

Zinc. The FOD for dissolved zinc was 86 percent. Zinc was detected at a mean concentration of 0.0027 mg/L, which is above the range of MDLs and within the range of MRLs. Therefore, the mean is a function of detection limits and estimated values. The CV for dissolved zinc was 1.02.

Lead. The FOD for dissolved lead was 25 percent. Lead was detected in 25 percent of samples at a mean concentration of 0.000087 mg/L, which is within the range of MRLs and MDLs. Therefore, the mean is a function of detection limits and estimated values. The CV for dissolved lead was 0.87.

Cadmium. The FOD for dissolved cadmium was 9 percent. Cadmium was detected at a mean concentration of 0.000013 mg/L, which is below the range of MDLs and MRLs. This indicates the mean concentration is largely a function of detection limits and estimated values. The CV for dissolved cadmium was 0.68.

Arsenic. The FOD for dissolved arsenic was 24 percent. Arsenic was detected at a mean concentration of 0.00031 mg/L, which is within the range of MRLs and MDLs. Therefore, the mean is largely a function of detection limits and estimated values. The CV for dissolved arsenic was 0.57.

Nickel. The FOD for dissolved nickel was 89 percent. Nickel was detected at a mean concentration of 0.00041 mg/L, which is above the range of MDLs and within the range of MRLs. As such, the mean combines a function of detection limits, estimated values, and some detected concentrations. The CV for dissolved nickel was 0.61.

Molybdenum. The FOD for dissolved molybdenum was 96 percent. Molybdenum was detected at a mean concentration of 0.00066 mg/L, which is within the range of MRLs and MDLs. Therefore, the mean is largely a function of detection limits and estimated values. The CV for dissolved molybdenum was 0.98.

Manganese. Dissolved manganese was detected in all samples at a mean concentration of 0.020 mg/L. The CV for dissolved manganese was 1.14, which indicates moderate variability in concentrations, similar to that seen for total manganese. This was the highest CV across dissolved trace elements.

Cyanides

Total Cyanide. The FOD for total cyanide was 9 percent. Total cyanide was detected at a mean concentration of 0.0028 mg/L, which is below the range of MRLs and within the range of MDLs. Therefore the majority of detected concentrations are estimated values below the limits of quantitation. The CV for total cyanide was 1.09.

WAD Cyanide. The FOD for WAD cyanide was 9 percent. WAD cyanide was detected at a mean concentration of 0.0027 mg/L, or essentially the same as the mean concentration for total cyanide. The CV for WAD cyanide was 0.68.

Organic Compounds

In 2004, 2005, and 2007, a small subset of surface water samples from the South Fork Koktuli River was analyzed for organic compounds (DRO, GRO, RRO, VOCs, SVOCs, PCBs, and pesticides). These compounds were not expected to be detected because of the remote, undeveloped nature of the area. Six samples were collected and analyzed to provide confirmation of this assumption. As shown in Appendix 9.1B, none of these constituents were detected in any surface water samples from the South Fork Koktuli River.

Dissolved Organic Carbon. As shown on Table 9.1-6, the FOD for dissolved organic carbon was 93 percent. Dissolved organic carbon was detected at a mean concentration of 1.36 mg/L, which is similar to but slightly below the mean concentration in North Fork Koktuli River and Upper Talarik Creek samples. The CV for organic carbon was 0.62, with a range of values between 0.22 and 4.09 mg/L.

Comparison with Water Quality Criteria

Field and physical parameters, major ions, nutrients, total and dissolved trace elements, and cyanides were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison with water quality criteria is presented in Table 9.1-13. Concentrations of most constituents met criteria. Concentrations were outside of the most stringent criteria in at least one sample for the following parameters:

- pH was outside the criteria range in 195 of 605 samples.
- DO was below the minimum criteria in 39 of 596 samples.
- Alkalinity was below the minimum criteria in 396 of 611 samples.
- WAD cyanide was above the maximum criteria in 8 of 598 samples.

The pH was below the criteria range of 6.5 in 194 samples (32 percent) across 18 locations, and above the criteria range of 8.5 in one sample (station SK100F from July 2004). Several locations had pH below the criteria range in more than 10 samples, with station SK100A having pH outside criteria most frequently (23 samples; Appendix 9.1B). Most pH extremes occurred in fall or winter, and pH was not consistently low at any one location. DO was below the minimum criteria in 6 percent of samples. These are typically short-term, intermittent dips in DO concentrations at a few locations. Alkalinity concentrations were below the minimum criteria in many samples from multiple locations.

WAD cyanide was naturally above the most stringent maximum criteria in 1.3 percent of samples, which is not unexpected given the large number of samples collected from the South Fork Koktuli River. Most sampling locations with WAD cyanide concentrations above criteria are in the upstream portion of the South Fork Koktuli River system near the deposit area and include both main stem (stations SK100D, SK100F, SK100G) and tributary (stations SK134A and SK133A) sample locations.

Nine metals had concentrations above the most stringent maximum criteria in at least one sample. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates.

- Aluminum (total: 72 of 601 samples),
- Antimony (total: 2 of 600 samples),
- Cadmium (total: 14 of 600 samples; dissolved: 5 of 593 samples),
- Copper (total: 249 of 601 samples; dissolved: 170 of 513 samples),
- Iron (total: 23 of 601 samples),
- Lead (total: 93 of 601 samples; dissolved: 30 of 477 samples),
- Manganese (total: 89 of 601 samples),
- Mercury (total: 2 of 599 samples), and
- Zinc (total: 5 of 601 samples; dissolved: 3 of 438 samples).

Copper had the greatest number of samples with concentrations naturally above the most stringent maximum criteria (41 percent of samples), followed by aluminum, manganese, and lead with concentrations above the most stringent maximum criteria in 12, 15, and 16 percent of samples, respectively. Cadmium, iron, and zinc had fewer than 2.5 percent of sample concentrations above the most stringent maximum criteria, which is not unexpected considering the large number of samples collected. Antimony and mercury are not trace elements specifically discussed herein; data for these trace elements are summarized in Appendix B.

Naturally occurring aluminum concentrations were above the most stringent maximum criteria in 72 samples from 15 locations. All samples from one main stem location (SK100E) and two tributary locations (SK116A and SK117A), both of which flow through the southern portion of the South Fork Koktuli River, have concentrations naturally above the most stringent maximum criteria.

Naturally occurring concentrations of copper were above the most stringent maximum criteria in 249 samples (41 percent) from all sampling locations above station SK100B1. The majority of naturally higher concentrations are in sampling locations within, or in proximity to, the general deposit location. The number and magnitude of copper concentrations above the most stringent maximum criteria decreased with increasing distance from the deposit area. With one minor exception, all concentrations at and downstream of station SK100B1 were below the most stringent criteria.

Manganese had 89 data points (15 percent) above the most stringent maximum criteria at nine locations, including the six main stem sampling locations closest to the general deposit area (stations SK100I, SK100H, SK100G, SK100F, SK100D, and SK100C) and two tributaries within the general deposit area (stations SK134A and SK133A).

Lead had 93 data points (15 percent) that were above the most stringent maximum criteria at 14 locations. In general, each sampling location had several concentrations naturally above the most stringent maximum criteria; no consistent pattern could be identified. This may indicate the deposit area is not the main source of the naturally occurring lead concentrations in the surface water of the South Fork Koktuli River, and these levels are sporadically present throughout the South Fork Koktuli River.

Iron had 23 data points (3.9 percent) above the most stringent maximum criteria at eight locations, generally consistent with those for manganese. The number and concentrations for copper and manganese above the most stringent maximum criteria decreased with increasing distance from the deposit area.

Spatial and Temporal Trend Analysis

The spatial trend analysis was conducted in three ways. First, regression analysis was conducted to identify any notable trends in total analyte concentrations from upstream to downstream for parameters routinely detected above MRLs. The purpose of this analysis was to determine if concentrations of specific constituents into the drainage along the course of the creek has effects on downstream concentrations at any sampling location.

Second, correlation analysis was conducted to compare streamflow and chemical concentrations. This analysis was prepared to compare the influence of streamflow on the concentration of constituents in the main stem of the South Fork Koktuli River.

Finally, stacked bar graphs were prepared, showing median analyte concentrations by location for each month. These graphs were prepared to determine whether concentrations of specific constituents into the river system along the course of the river have effects on downstream concentrations at any sampling location.

For the first two analyses, median analyte concentrations for each sample location were ordered from upstream to downstream (Table 9.1-14). A linear regression analysis was performed for parameters routinely detected above detection limits. Linear R^2 values and p-values from the Mann-Whitney U-Test were evaluated to identify any significant trends. Spatial regression results are presented in Table 9.1-15, and the significant results are shown graphically in Appendix 9.1E and further discussed below.

Significant negative trends (decreasing concentrations with downstream distance) were apparent from the regression analysis for the following parameters:

- TDS
- Sodium
- Potassium
- Sulfate
- Fluoride
- Hardness
- Iron
- Copper
- Nickel
- Molybdenum
- Cyanide

In general, the trace element concentration trend is to decrease with increasing distance from the deposit area. The general trend of decline in elemental concentrations with distance indicates an upstream source

(i.e., the deposit area) with somewhat higher concentrations, and decreasing concentrations along the stream channel as the streamflow increases. The decrease in elemental concentrations may also reflect, at least in part, natural attenuation processes such as chemical precipitation, adsorption to sediments, and/or uptake by aquatic organisms.

Streamflow effects on concentrations were evaluated by plotting both median concentrations and median daily streamflow measurements (in cubic feet per second) in log scale from upstream to downstream on the same graph for parameters routinely detected above detection limits. These graphs are presented in Figures 9.1-48 through 9.1-67).

Inverse trends between concentration and streamflow are apparent for many constituents. This indicates, for some parameters, concentration is a function of streamflow.

High flow can lead to additional constituent mobilization from the sediment (i.e., scouring) during both snowmelt in the spring and heavy rains in the fall, which can introduce additional constituents into the downstream locations, particularly for water-soluble ions like sodium and chloride. For parameters that indicate the opposite trend, water with low concentrations of these constituents (e.g., TSS) may enter the main stem of the river from tributaries, resulting in lower concentrations as the water is mixed in the main stem.

The correlative parameters (Figures 9.1-48 through 9.1-67) and stacked bar graphs (Figures 9.1-68 through 9.1-89) are discussed by parameter group below. Only graphs for parameters consistently detected above detection limits and/or with significant differences identified are presented and discussed in the following text.

Temporal line graphs were prepared to assess seasonal tendencies for total concentrations of each analyte routinely detected above detection limits at each sampling location (Appendix 9.1F). Chemical- and parameter-specific graphs were prepared where each line represents a different sampling location, with month across the x-axis and median concentration on the y-axis. In general, the absence of a bar for a station means the location wasn't sampled often. In fewer cases, the absence of a bar for a station indicates the lack of detections at that location for the constituent. Note that these graphs are not meant to imply cumulative values, but are intended to be used solely to compare concentrations at different locations across months.

Field and Physical Parameters

Total Dissolved Solids. TDS concentrations decline steadily from station SK100G to station SK100C (Figure 9.1-48). Further downstream, concentrations of TDS stay generally consistent.

The stacked bar graph in Figure 9.1-68 indicates that relatively consistent concentrations are present at most locations and months for TDS. The lowest concentrations generally occurred in May during snowmelt. Exceptions are evident for station SK116A, which only has detectable median concentrations during the fall and early winter, and station SK100C, which is below detectable levels in February or March. The trend observed of lower concentrations of TDS in downstream locations is likely because the primary source of constituents to the South Fork Koktuli is from the deposit area. If additional dissolved solids and hardness-related ions were added to the system in proportion to the water flow, concentrations

would remain consistent with water flow. However, as water flow increases downstream of the deposit area, the concentrations are diluted.

pH (Field). Downstream sample locations generally exhibit lower pH than upstream sample locations (Figure 9.1-49).

The stacked bar graph in Figure 9.1-69 indicates that relatively consistent concentrations are present at most locations and months for pH. Generally, pH was variable seasonally in upstream locations, with slightly higher pH in the spring and again in the fall. An acidic trough, with a median pH near 5.0, was exhibited in November at downstream main stem location SK100C. The source of this acidity is not known but represents a natural condition at this location.

Total Suspended Solids. TSS is generally higher in upstream locations than in downstream locations (Figure 9.1-50).

The stacked bar graph in Figure 9.1-70 indicates that concentrations fluctuate across most locations and months for TSS. For many stations, TSS had a relatively consistent primary peak in May, with smaller peaks in August and November. This pattern is observed regardless of distance from the general deposit area but is more pronounced closer to the general deposit area. This likely represents additional suspended particulates from the high flows associated with snowmelt across the basin at this time.

Major Ions

All reported medians for fluoride were below MRLs, indicating many of the sample results are estimated concentrations. Except for sodium and sulfate, variability of the data was high, as indicated by the large confidence intervals shown in the figures.

Differences in temporal trends among ions are likely attributed to the same factors discussed for trace elements above. Given the generally high water solubility of these major ions relative to trace elements, peaks and influx into the system are more likely largely attributed to water movement (e.g., snowmelt in the spring, rainfall in the fall) than to influx of constituents adsorbed to particulates. Seasonal variations become progressively less evident at downstream locations.

Sodium. Sodium is present at the highest median concentration at station SK100G, and then declines steadily to location SK100C, where concentrations stay generally consistent further downstream (Figure 9.1-51).

The stacked bar graph in Figure 9.1-71 indicates consistent concentrations are present at most locations and months for total sodium. Seasonal patterns were evident from the temporal line graph for sodium (Appendix 9.1F), where median concentrations were generally consistent except for May, when lower concentrations were evident. Sodium also exhibited a unique maximum median concentration in December at location SK119A, a tributary just downstream from station SK100C. Downstream locations showed no discernible seasonal trends.

Potassium. Potassium displays consistent decreases in concentration in relation to increasing distance from the deposit area from station SK100G to station SK100B, then it increases slightly at station SK100A (Figure 9.1-52).

Potassium has relatively consistent concentrations across most sample locations over time, possibly because of its high water solubility. Concentrations at several locations are slightly higher in the spring and lower in the summer (Figure 9.1-72).

Alkalinity, Total. Alkalinity declines from station SK100G to its lowest concentration at station SK100C, then increases and stabilizes in further downstream locations (Figure 9.1-53).

The stacked bar graph in Figure 9.1-73 indicates relatively consistent concentrations are present at most locations and months for total alkalinity. Alkalinity exhibits peaks in March and August at most locations, which likely correspond to conditions of low flow. This pattern was evident regardless of distance from the general deposit area. Overall concentrations are lowest in May and June, consistent with conditions of high flow.

Sulfate. Steadily decreasing concentrations of sulfate occur with distance downstream from station SK100G (Figure 9.1-54).

The stacked bar graph in Figure 9.1-74 indicates consistent concentrations are present at most locations and months for sulfate. Seasonal patterns were evident from the temporal line graph for sulfate (Appendix 9.1F), where median concentrations were generally consistent except for May, when lower concentrations were evident. Downstream locations showed no discernible seasonal trends.

Chloride. Chloride concentrations tend to be higher as flow increases (Figure 9.1-55).

The stacked bar graph in Figure 9.1-75 indicates generally consistent concentrations are present at most locations and months for chloride. Seasonal patterns were evident from the temporal line graph for chloride (Appendix 9.1F). Overall concentrations decline slightly during the summer months and return to the higher year-round values in the fall. Median concentrations peak twice a year in spring and fall. Downstream locations showed less discernible trends than upstream locations.

Fluoride. The medians for fluoride were below MRLs, and no streamflow graphs were developed. The stacked bar graph in Figure 9.1-76 indicates consistent concentrations are present at most locations and months for fluoride, but several locations have detectable concentrations in only some months.

Fluoride median concentrations are greatest for several locations in September.

Hardness as $CaCO_3$ (Not Filtered). Hardness concentrations decline steadily from station SK100G to station SK100C. Further downstream, hardness concentrations increase at location SK100B1 and then decrease at the two furthest downstream main stem sampling locations (Figure 9.1-56). The trend observed for hardness (unfiltered) is likely because the primary source of loading to the South Fork Koktuli is from the general deposit area. If additional dissolved solids and hardness-related ions were added to the system in proportion to the water flow, concentrations would remain consistent with water flow. However, as water flow increases downstream of the deposit area, the concentrations are diluted.

The stacked bar graph in Figure 9.1-77 indicates relatively consistent concentrations in the system are present at most locations, although concentrations at most stations are lowest in May and June. Downstream locations showed less discernible seasonal trends.

Nutrients

Total Nitrate+Nitrite (as N). Total nitrate+nitrite (as N) demonstrates lower concentrations at stations SK100C and SK100A relative to other locations. No relationship with flow is apparent (Figure 9.1-57).

Total nitrate+nitrite (as N) had a peak in the fall months, with a lower peak occurring in May at most locations (Appendix 9.1F). Conversely, low concentrations of total nitrate+nitrite (as N) occur at most locations in the summer months of June through August relative to other months, with some exceptions, including station SK124A where concentrations were highest during June, and station SK100F where concentrations were highest in August (Figure 9.1-78).

Phosphorus. Phosphorus demonstrates lower concentrations between stations SK100B1 and SK100B relative to other locations, which suggests an inverse relationship with flow (Figure 9.1-58).

Phosphorus was detected in all months at most locations, with the highest concentrations usually occurring in May (Figure 9.1-79). However, median concentrations of phosphorus were mostly below MRLs, indicating the majority of data points represent estimated concentrations. Phosphorus median concentrations tended to be higher in late spring and early summer months, with a notable exception of a November peak at station SK133A.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any samples. Therefore, this analyte was not graphically analyzed.

Trace Elements

Peaks observed in the summer and early fall months (July through September) may be attributed to lower water volume during the dry season, combined with relatively consistent concentrations. The high concentrations of some elements observed in the spring (April through June) could be a result of snowmelt, during which time elements may be introduced to the river system with concentrations that are greater than the dilution of the higher flow rates. Concentration peaks observed in fall months (September through November) are likely related to increased precipitation during these months, and the resulting transport of elements to the river system through increased runoff.

Iron. Iron displays consistent decreases in concentration in relation to streamflow; concentrations decline with downstream distance, and hence also with increasing distance from the deposit area. Median concentrations of iron peak at the station SK100G location, decline through location SK100B1, and then stabilize further downstream (Figure 9.1-59).

The stacked bar graph in Figure 9.1-80 generally indicates consistent concentrations at most locations and months for this analyte. Concentrations at different locations vary, with the highest median concentrations from stations SK100F, SK100G, and SK136H (also called SK136A).

Median concentrations of iron showed different patterns at different location. In upstream locations, which are either within or close to the general deposit area, iron concentrations generally appear to peak in May and August; however, the highest peak observed in these upstream samples was in January at main stem location station SK100G. Further downstream locations (station SK119A to station SK100A) show only a small peak in May, with a smaller, more extended increase in concentrations in the fall.

Copper. Copper displays consistent decreases in concentration as streamflow increases downstream. Downstream locations are also further from the general deposit area. Median concentrations of iron peak at the SK100G location, decline through location SK100B1, and then stabilize further downstream (Figure 9.1-60).

The stacked bar graph in Figure 9.1-81 indicates that the greatest concentrations of copper are consistently found at stations SK100G, SK100I (also known as SK136A), and SK100H (also known as SK136B); these stations are located either in the upper reaches of the South Fork Koktuli River that flow through the deposit area or immediately downstream of this area. Concentrations are generally lowest in winter and highest during spring.

Seasonal patterns were evident from the temporal line graph for copper. A pronounced pattern for copper can be seen; median concentrations of copper were observed to peak twice a year, in spring and summer. This is most evident at upstream locations, and is muted in further downstream locations. The highest median concentrations were seen in main stem sampling location station SK100H (also known as SK136A), located within the deposit area. These sampling locations are within and downstream from the deposit area.

Zinc. Zinc declines slightly as streamflow increases but increases at station SK100C relative to other locations (Figure 9.1-61).

The stacked bar graph in Figure 9.1-82 generally indicates consistent concentrations are present at most locations and months for this analyte.

Zinc exhibits two seasonal peaks, one in winter (February) and one in summer (July). This pattern is different from the other trace elements. The highest median, approximately three times higher than any other month or location, is at tributary location SK124A in February. Locations SK100I (also known as SK136B) and SK131A also had high median concentrations in February, July, and/or December. Zinc has the highest water solubility of the trace elements included in this evaluation; this characteristic may be one contributing factor for the somewhat different seasonal pattern seen for zinc.

Lead. Lead shows relatively consistent median concentrations in the main stem locations with distance downstream. Median concentrations were all just above MRLs (Figure 9.1-62).

High median concentrations of lead were observed in tributary location 124A in February and tributary location 119A in December (Figure 9.1-83). The latter tributary flows through the mid-northern portion of the South Fork Koktuli River and does not collect surface water from the general deposit area. Therefore, lead concentrations do not appear to be correlated with the general deposit area.

Lead does not show any evident seasonal patterns. Downstream sample locations indicate higher concentrations in early spring than other seasons, while locations further upstream exhibited peaks in December (station SK119A) and June (station SK133A). Concentrations were generally low in July through November and generally highest in winter and spring, with some exceptions. These exceptions include station SK100C, which was highest in July, and station SK100I (also known as SK136B), which was highest in August.

Cadmium. Cadmium median concentrations were above MRLs only at station SK100B1. Therefore, no trends could be identified in the data (Figure 9.1-63).

Cadmium does not show any evident seasonal patterns. Concentrations are generally quite low across months, with the exception of station SK100H (also known as SK136A), located upstream and within the general deposit area, in late fall (Figure 9.1-84). Cadmium median concentrations are generally below MRLs at downstream sampling locations. There is a wide variability in cadmium concentrations by month and location, likely associated with concentrations below MRLs for most samples.

Arsenic. Arsenic median concentrations were above MRLs only at station SK100B1. Therefore, no trends could be identified in the data (Figure 9.1-64).

Arsenic median concentrations are generally near the MRLs, making identification of seasonal patterns difficult. No pattern is evident at station SK131A, a tributary that drains into Frying Pan Lake, one of the few locations consistently above MRLs (Figure 9.1-85). Overall, arsenic concentrations were generally lower in the winter and higher in the summer.

Nickel. Nickel displays a clear and consistent pattern of decreasing concentrations in relation to increasing distance from the general deposit area, or an inverse relationship with flow (Figure 9.1-65). Sample locations SK100H, SK100G, and SK100I had the highest median concentration of nickel (Appendix 9.1F).

Nickel median concentrations are generally higher in winter and summer from sample locations in and near the general deposit area. This trend is not discernible at downstream sampling locations. The stacked bar graph in Figure 9.1-86 indicates that station SK100I (also known as 136B) has the highest median nickel concentrations. The greatest concentrations of nickel were generally in winter months.

Molybdenum. Molybdenum displays a clear and consistent pattern of decreasing concentrations in relation to increasing distance from the general deposit area, or an inverse relationship with flow. Median concentrations of molybdenum peaked at the SK100G location (Figure 9.1-66).

The lowest contribution of molybdenum generally occurs in spring; other seasons generally have higher overall concentrations. Concentrations of molybdenum were bimodal at sampling locations in and near the general deposit area, with peaks in winter and summer. The most pronounced seasonal pattern was observed at sampling location SK100H (also known as SK136A), located within the deposit area. This location had the highest median molybdenum concentrations across all months throughout the system. The seasonal pattern is not apparent at sampling location SK133A and further downstream. Sample locations SK100G, SK100I, and SK134A generally had the next highest median concentrations of molybdenum.

Cyanides

Total Cyanide. Total cyanide had consistent median concentrations just above MRLs from upstream locations down to station SK100C, when concentrations then gradually declined below MRLs (Figure 9.1-67).

The median concentrations of total cyanide were all near or below MDLs except in June, indicating they are largely estimated concentrations. The total cyanide median concentrations at eight sampling locations are highest in June, particularly at main stem locations SK100B, SK100D, and SK100F, and at tributary location SK134A located within the deposit area. The highest total cyanide median concentrations come from stations SK134A and SK100B in this month (Figure 9.1-88). Station SK134A is located on the border of the deposit area, while station SK100B is located more than 10 miles downstream on the main stem of the river. Based on these observations, sources other than the deposit area appear to be contributing to the naturally occurring concentrations of total cyanide detected at these locations.

WAD Cyanide. The median concentrations for WAD cyanide were below MRLs at all locations, so no streamflow graph was developed.

WAD cyanide had a median concentration below MRLs in most months and showed a pattern similar to that of total cyanide. Location SK134A provides the highest concentrations of WAD cyanide in June. WAD cyanide had a peak median concentration in June at tributary location SK134A. However, WAD cyanide also had an earlier March peak for location SK100D, but a later August peak for downstream location SK100B, than was observed for total cyanide. No consistent patterns are evident from evaluation of the stacked bar graphs for WAD cyanide (Figure 9.1-89).

9.1.8.3. Results and Discussion: Upper Talarik Creek

This section presents the findings of the surface water quality study in the Upper Talarik Creek drainage in the mine study area. Surface water samples and measurement of physical and chemical parameters were obtained from the creek and its tributaries to assess the spatial and temporal variability of field and physical parameters, major ions, nutrients, trace elements, and cyanides in the mine study area. The analysis was conducted using data acquired during the 5-year period from 2004 to 2008.

The Upper Talarik Creek study area encompasses approximately 20 miles of the main stem of the creek, originating from just north of the deposit area and ending near Lake 2 (Figure 9.1-3), approximately 6 miles north of Iliamna Lake. It includes five tributaries.

As shown in Table 9.1-7, 509 surface water samples were collected and analyzed from 15 sampling locations in Upper Talarik Creek and its tributaries between 2004 and 2008. The number of data points differs among constituents because some data were analyzed only in some seasons (e.g., phosphorus, total orthophosphate), resulting in fewer data points as well.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, cyanides, and organic compounds.

Field and Physical Parameters

Eight field and physical parameters were measured in Upper Talarik Creek surface water samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-7. The overall CV for this group of 0.74 is similar to, but slightly less than, that for North and South Fork Koktuli River samples.

Total Dissolved Solids. The FOD for TDS was 99 percent. The TDS mean concentration is low relative to rivers in more-developed areas, with a mean concentration of 51.2 mg/L. The CV for TDS was 0.37.

pH (Field). The mean pH was 6.99. The CV for pH was 0.091. A pH median of 7.01 indicates the water of the Upper Talarik Creek is neutral.

Dissolved Oxygen. DO was detected in all samples at a mean concentration of 10.5 mg/L. The CV for DO was 0.19, indicating very low variability in this drainage. Overall, DO was high relative to typical rivers in the continental U.S., indicating the surface water is well aerated.

Water Temperature. The mean water temperature was 4.04^{o}C, which is slightly colder than water in either the North or South Fork Koktuli River samples. The CV for water temperature was 0.98. Water temperature is cold, with a median temperature of 2.53^{o}C.

Specific Conductivity (Field). The mean concentration for specific conductivity was 73.4 uS/cm. The CV for specific conductivity was 0.34.

Turbidity. The mean concentration for turbidity was 1.75 NTU. Turbidity is similar to that in South Fork Koktuli River samples,, and higher than that in the North Fork Koktuli River. The CV for turbidity was 1.31.

Total Suspended Solids. The FOD for TSS was 94 percent. The TSS mean concentration is low relative to rivers in more-developed areas, with mean a concentration of 2.52 mg/L. The CV for TSS was 1.58.

Oxidation Reduction Potential. The FOD for ORP was 99.8 percent. ORP was detected at a mean concentration of 111 mV, with a range of -214 to 519 mV. The CV for ORP was 0.82.

Major Ions

Upper Talarik Creek surface water data for nine parameters (calcium, magnesium, sodium, and potassium [total and dissolved, as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-7. Data for other analyzed parameters in this group can be found in Appendix 9.1B. The overall CV for this group of 0.48 is similar to that in South Fork Koktuli River samples, but higher than North Fork Koktuli River samples.

Most of the major ions, except alkalinity (99 percent FOD), sulfate (99.6 percent FOD), and fluoride (63 percent FOD), were detected in all samples. Calcium and sulfate were detected at the highest mean concentrations of the individual ions; fluoride had a mean concentration one to three orders of magnitude lower than the other major ions (Table 9.1-7).

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 8.91 mg/L. Calcium is the most abundant major ion in Upper Talarik Creek water samples. The CV for total calcium was 0.42.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 8.77 mg/L. Calcium is the most abundant major ion in Upper Talarik Creek water samples. The CV for dissolved calcium was 0.3.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 2.13 mg/L. The CV for total magnesium was 0.5.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 2.12 mg/L. The CV for dissolved magnesium was 0.46.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.85 mg/L, making it the third most abundant ion in Upper Talarik Creek samples. The CV for total sodium was 0.44.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.82 mg/L. The CV for dissolved sodium was 0.32.

Potassium (Total). Total potassium was detected in all samples at a mean concentration of 0.44 mg/L, making it one of the more abundant ions in river samples for this drainage. The CV for total potassium was 0.49.

Potassium (Dissolved). Dissolved potassium was detected in all samples at a mean concentration of 0.44 mg/L. The CV for dissolved potassium was 0.43.

Alkalinity, Total. The FOD for total alkalinity was 99 percent. Total alkalinity was detected at a mean concentration of 31.8 mg/L. The CV for total alkalinity was 0.34.

Sulfate. The FOD for sulfate was 99.6 percent. Sulfate was detected at a mean concentration of 5.48 mg/L, second in abundance to calcium of the major ions in the Upper Talarik Creek water samples. The CV for sulfate was 1.43, which is much higher than the other constituents in this group.

Chloride. Chloride was detected in all samples at a mean concentration of 0.7 mg/L. The CV for chloride was 0.29, implying a small range of concentrations across samples as shown on Table 9.1-7.

Fluoride. The FOD for fluoride was 63 percent. Fluoride was detected at a mean concentration of 0.039 mg/L, which is the lowest across the major ions in Upper Talarik Creek water samples. Fluoride concentrations were mostly below MRLs, indicating the mean is a function of detection limits and estimated values. The CV for fluoride was 0.61.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected in all samples at a mean concentration of 30.6 mg/L. The CV for hardness as $CaCO_3$ (not filtered) was 0.32. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria but harder than water in the South Fork Koktuli River or North Fork Koktuli River.

Hardness as $CaCO_3$ (Filtered). Hardness as $CaCO_3$ (filtered) was detected at a mean concentration of 26.5 mg/L. The CV for hardness as $CaCO_3$ (filtered) was 0.42. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria but harder than water in the South Fork Koktuli River or North Fork Koktuli River.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-7.

Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1B.

Nutrients were not detected in all samples. Total nitrate+nitrite (as N) was detected in 88 percent of surface water samples, phosphorus was detected in 77 percent of samples, and nitrogen, total ammonia (as N) was detected in only 23 percent of samples. Total orthophosphate [as P] was not detected in any of the water samples from Upper Talarik Creek.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.97 (total phosphorus) to 1.57 (total ammonia as N). The CV for all nutrients was 1.31.

Nitrogen, Total Ammonia (as N). The FOD for nitrogen, total ammonia (as N) was 23 percent. Total ammonia (as N) was detected at a mean concentration of 0.036 mg/L, which is below the MRLs. Therefore, the majority of concentrations were below MRLs. The highest concentration was 1.03 mg/L. The CV for nitrogen, total ammonia (as N) was 1.57, which is higher than that for the major ions for river samples in this drainage.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 88 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.25 mg/L and was dominated by nitrate, as shown in Appendix 9.1B. The CV for total nitrate+nitrite (as N) was 1.38.

Phosphorus. The FOD for phosphorus was 77 percent. Phosphorus was detected at a mean concentration of 0.019 mg/L, which is within the range of MRLs and MDLs. The mean is, in part, a function of detection limits and estimated values. The CV for phosphorus was 0.97.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any Upper Talarik Creek samples.

Total Trace Elements

Data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-7 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1B.

Total barium was detected in all samples. Five other trace elements (aluminum, iron, copper, nickel, and manganese) were detected in more than 90 percent of samples, while total cadmium was detected in the fewest samples (8 percent FOD). Total iron was the only parameter with a mean concentration above 0.1 mg/L (0.28 mg/L). Aluminum and manganese were present at the next highest concentrations, both with means over 0.01 mg/L. Cadmium was detected at the lowest concentrations with a mean of 0.000013 mg/L.

The overall CV for total trace elements in Upper Talarik Creek surface water samples was 1.86, which is higher than CVs for total trace elements in other drainages and higher than major ions.

Aluminum. The FOD for total aluminum was 95 percent. Aluminum was detected at a mean concentration of 0.075 mg/L. The CV for total aluminum was 1.46. The majority of aluminum samples were above the limits of detection.

Barium. Total barium was detected in all samples at a mean concentration of 0.0061 mg/L. The CV for total barium was 0.54.

Iron. The FOD for total iron was 97 percent. Iron was detected at a mean concentration of 0.28 mg/L, making it the most abundant of the evaluated trace elements for river samples in this drainage. The CV for total iron was 0.92.

Copper. The FOD for total copper was 93 percent. Copper was detected at a mean concentration of 0.00057 mg/L. The CV for total copper was 1.78, and represents the difference in concentrations from sample locations near the general deposit area and those further downstream.

Zinc. The FOD for total zinc was 66 percent. Zinc was detected at a mean concentration of 0.0022 mg/L. The CV for total zinc was 1.31.

Lead. The FOD for total lead was 29 percent. Lead was detected at a mean concentration of 0.00037 mg/L. The CV for total lead was 5.70, indicating substantial variability in this constituent.

Cadmium. The FOD for total cadmium was 8 percent. Cadmium was detected at a mean concentration of 0.000013 mg/L, which is below the range of MRLs. This indicates that detected concentrations were largely estimated values. The CV for total cadmium was 1.31.

Arsenic. The FOD for total arsenic was 60 percent. Arsenic was detected at a mean concentration of 0.00084 mg/L, which is within the range of MRLs, indicating the mean is largely a function of detection limits and estimated values. The CV for total arsenic was 1.19.

Nickel. The FOD for total nickel was 91 percent. Nickel was detected at a mean concentration of 0.00052 mg/L. Nickel was more abundant in Upper Talarik Creek samples than in those from the North Fork Koktuli River, but similar in FOD to South Fork Koktuli River samples. The CV for total nickel was 1.16.

Molybdenum. The FOD for total molybdenum was 85 percent. Molybdenum was detected at a mean concentration of 0.00025 mg/L, which is within the range of MRLs and MDLs for this element. Therefore, detected molybdenum concentrations represent a mixture of estimated and measured concentrations. The CV for total molybdenum was 4.06, which is high relative to most trace elements. The high variability is most likely due to the differences in proximity of sample locations to the general deposit area.

Manganese. The FOD for total manganese was 99.6 percent. Manganese was detected at a mean concentration of 0.026 mg/L, which is about double the mean concentration in North Fork Koktuli River water samples and about 30 percent higher than the mean concentration in South Fork Koktuli River samples. The CV for total manganese was 1.07.

Dissolved Trace Elements

Data for dissolved aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-7 and discussed below. Other dissolved trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, selenium, silicon, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1B.

Dissolved barium was detected in all samples. Four other trace elements (iron, copper, nickel, and manganese) were present in more than 90 percent of samples, while dissolved cadmium was detected in the fewest samples (7 percent FOD). Dissolved iron was the only parameter with a mean concentration above 0.1 mg/L (0.11 mg/L). Aluminum and manganese were present at the next highest concentrations, both with means over 0.01 mg/L. Cadmium and lead were present at the lowest concentrations, with mean concentrations less than 0.0001 mg/L.

Dissolved trace elements in Upper Talarik Creek surface water samples showed less variability than total trace elements, with an overall CV of 0.94.

Aluminum. The FOD for dissolved aluminum was 87 percent. Aluminum was detected at a mean concentration of 0.013 mg/L, or about $1/6^{th}$ the mean concentration of total aluminum. The mean concentration is within the range of MRLs and MDLs, indicating many of the values are estimated concentrations. The CV for dissolved aluminum was 1.1.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0055 mg/L. The CV for dissolved barium was 0.41.

Iron. The FOD for dissolved iron was 92 percent. Iron was detected at a mean concentration of 0.11 mg/L and was the most abundant of the evaluated trace elements. The CV for dissolved iron was 0.83.

Copper. The FOD for dissolved copper was 96 percent. Copper was detected at a mean concentration of 0.00042 mg/L, which is within the range of MRLs and MDLs for this element. This indicates that many of the dissolved copper detected values represent estimated concentrations. The CV for dissolved copper was 0.89.

Zinc. The FOD for dissolved zinc was 73 percent. Zinc was detected at a mean concentration of 0.002 mg/L, which is within the range of MRLs for this element. The CV for dissolved zinc was 1.09.

Lead. The FOD for dissolved lead was 24 percent. Lead was detected at a mean concentration of 0.000067 mg/L. The CV for dissolved lead was 1.53, which was much lower than that for total lead in river samples for this drainage.

Cadmium. The FOD for dissolved cadmium was 7 percent. Cadmium was detected at a mean concentration of 0.000012 mg/L, which is below the MRLs for this element. This indicates the mean is a function of detection limits and estimated concentrations. The CV for dissolved cadmium was 0.77.

Arsenic. The FOD for dissolved arsenic was 55 percent. Arsenic was detected at a mean concentration of 0.00067 mg/L, which is within the range of MDLs and MRLs for this element. Therefore, many of the detected values represent estimated concentrations. The CV for dissolved arsenic was 0.98.

Nickel. The FOD for dissolved nickel was 98 percent. Nickel was detected at a mean concentration of 0.00063 mg/L, which is within the range of MRLs. Many of the detected nickel concentrations are estimated values. The CV for dissolved nickel was 1.04.

Molybdenum. The FOD for dissolved molybdenum was 87 percent. Molybdenum was detected at a mean concentration of 0.0002 mg/L, which is within the range of MRLs and MDLs for this element. Therefore,

the mean concentration is driven by the detection limits and estimated values. The CV for dissolved molybdenum was 0.51, which was an order of magnitude lower in variability than total molybdenum for river samples in this drainage.

Manganese. The FOD for dissolved manganese was 99.8 percent. Manganese was detected at a mean concentration of 0.021 mg/L. The CV for dissolved manganese was 1.19.

Cyanides

Total Cyanide. The FOD for total cyanide was 11 percent. Total cyanide was detected at a mean concentration of 0.0015 mg/L. The CV for total cyanide was 1.62.

WAD Cyanide. The FOD for WAD cyanide was 11 percent. WAD cyanide was detected at a mean concentration of 0.0015 mg/L, which is identical to the total cyanide value. The CV for WAD cyanide was 1.57.

Organic Compounds

In 2004, 2005, and 2007, a small subset of surface water samples from Upper Talarik Creek were analyzed for organic compounds (DRO, GRO, RRO, VOCs, SVOCs, PCBs, and pesticides). These compounds were not expected to be detected because of the remote, undeveloped nature of the area. Six samples were collected and analyzed to provide confirmation of this assumption. As shown in Appendix 9.1B, none of these constituents were detected in any surface water samples from Upper Talarik Creek.

Dissolved Organic Carbon. Dissolved organic carbon was analyzed in 191 samples. Data are summarized in Table 9.1-7. The FOD for dissolved organic carbon was 95 percent. Dissolved organic carbon was detected at a mean concentration of 1.57 mg/L. The CV was 0.82, with a range of concentrations from 0.16 to 8.18 mg/L.

Comparison with Water Quality Criteria

Field and physical parameters, major ions, nutrients, total and dissolved trace elements, and cyanides were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates.

A summary of the comparison is presented in Table 9.1-16. Concentrations of most constituents met the most stringent criteria. Concentrations were outside of the most stringent criteria in at least one sample for the following parameters:

- pH was outside the criteria range in 77 out of 500 samples.
- Alkalinity was below the minimum criteria in 54 out of 497 samples.

- DO was below the minimum criteria in 9 out of 494 samples.
- WAD cyanide was above the maximum criteria in 9 out 484 of samples.

The pH was below the most stringent criteria range of 6.5 in 76 samples (15 percent) across nine locations and above the criteria range of 8.5 in one sample (station UT138A from May 2004). The one sample with a pH of 14.6 is likely an error. Location UT119B had the highest frequency of pH below the most stringent criteria. Both of these locations are downstream from the general deposit area. The pH extremes did not occur in the summer months. Most pH extremes occurred in winter or spring, during periods just before and during snowmelt.

WAD cyanide concentrations had naturally occurring concentrations above most stringent maximum criteria at six locations (1.5 percent of samples), all in the upstream portion of the Upper Talarik Creek drainage near the general deposit area, and include both main stem stations(UT100D and UT100E) and tributary) sample locations (UT135A, UT138A, UT141A, and UT146A.

Concentrations were above the most stringent maximum criteria in at least one sample for the following trace elements:

- Aluminum (total: 107 of 486 samples; dissolved: 4 of 479 samples).
- Antimony (total: 3 of 486 samples).
- Iron (total: 6 of 486 samples).
- Copper (total: 35 of 486 samples; dissolved: 9 of 350 samples).
- Lead (total: 40 of 486 samples; dissolved: 5 of 399 samples).
- Cadmium (total: 7 of 481 samples; dissolved: 4 of 479 samples).
- Arsenic (total: 1 of 486 samples).
- Manganese (total: 71 of 486 samples).
- Silver (total: 1 of 486 samples).

For aluminum, the majority of naturally occurring concentrations above the most stringent maximum criteria were primarily from locations UT135A, UT100E, UT138A, and UT141A. The tributary in which station UT141A is located flows through the eastern portion of the general deposit area, and the other two are located nearby; the majority of these samples were collected between April and June. Iron and cadmium concentrations were naturally above the most stringent maximum criteria in about 1 percent of samples, which is not surprising given the large number of samples collected from the Upper Talarik Creek drainage. Antimony and silver are not trace elements specifically discussed herein; data for these trace elements are summarized in Appendix B.

The lead concentrations naturally above the most stringent maximum criteria do not appear to be related to proximity to the general deposit area. These naturally elevated concentrations may therefore be the result of localized sources that are not continuous throughout the drainage.

Manganese concentrations were naturally above the most stringent maximum criteria at eight locations, including five main stem and three tributary locations, but all concentrations were less than 3 times the

most stringent maximum criteria. No concentrations above the most stringent maximum criteria were observed in the most downstream sample location (UT100A); only two samples each at stations UT100B and UT100C2 had concentrations above maximum criteria; and a single sample at station UT100C1 had one concentration above the most stringent maximum criteria. The majority of manganese concentrations naturally above the most stringent maximum criteria were observed in samples from two locations, stations UT146A and UT100D. Sample location UT146A is in a tributary that flows through the general deposit area, and station UT100D is the closest main stem location downstream of station UT146A (except station UT100D1, from which only nine samples were collected across only 2 years). The association of these two sample locations with the area containing the deposit likely explains the majority of naturally elevated manganese concentrations occurring there.

Spatial and Temporal Trend Analysis

This analysis was conducted in three ways, as described in Section 9.1.8.1. The upstream-to-downstream sample location ordering used for the first two analyses is presented in Table 9.1-17. Spatial regression results are presented in Table 9.1-18, and the significant results are shown graphically in Appendix 9.1E and further discussed below.

Significant positive trends (increasing concentrations or values with downstream distance) were apparent from the regression analysis for the following parameters:

- Chloride
- Arsenic
- Molybdenum

Significant negative trends (decreasing concentrations with downstream distance) were apparent from the regression analysis for the following parameters:

- TDS
- Potassium
- Sodium
- Alkalinity
- Sulfate
- Hardness

Streamflow effects on concentrations were evaluated by plotting both median analyte concentrations and median daily streamflow measurements (in cubic feet per second) in log scale from upstream to downstream on the same graph for parameters routinely detected above detection limits. Streamflow increased from upstream to downstream (Figures 9.1-90 through 9.1-108).

Both direct (e.g., chloride) and inverse relationships (e.g., TDS) with streamflow are apparent, which indicates concentration is a function of streamflow for some constituents.

High flow can lead to higher concentrations in surface water from the constituents adsorbed to sediment (i.e., scouring) during both snowmelt in the spring and heavy rains in the fall, which can lead to higher

concentrations in the downstream locations, particularly for water soluble ions like chloride. For parameters that indicate the opposite trend, water low in these parameters (e.g., TDS) may be entering the main stem of the river from tributaries, resulting in lower concentrations as the water is mixed in the main stem.

The correlative parameters (Figures 9.1-90 through 9.1-108) and stacked bar graphs (Figures 9.1-109 through 9.1-130) are discussed by parameter group below. Only graphs for parameters consistently detected above detection limits and/or with significant differences identified are presented and discussed in the following text.

Temporal line graphs were prepared to assess seasonal tendencies for total concentrations of each analyte routinely detected above MRLs at each sampling location (Appendix 9.1F). For each chemical-specific graph, each line represents a different sampling location, with month across the x-axis and median concentration on the y-axis.

Field and Physical Parameters

Evaluation of the temporal line graphs revealed several general trends, although differences by location were apparent in almost all cases.

Total Dissolved Solids. TDS exhibited higher median values at the two most upstream locations, UT100E and UT100D, both of which are associated with the general deposit area (Figure 9.1-90). The median value was substantially lower at the next downstream location (UT100C2) and remained generally lower, while fluctuating, in all sample locations further downstream. This is likely attributed to dilution from the deposit area as additional water enters the system downstream of the general deposit area.

The stacked bar graph (Figure 9.1-109) indicates that higher TDS concentrations generally occur in winter and fall months at most stations, with lowest concentrations generally occurring in spring (e.g., April) for most locations. Contributions from individual locations are relatively consistent over the seasons for most stations.

This trend of lower concentrations in spring becomes less apparent at downstream sampling locations.

pH (Field). The pH values fluctuated by sample location, but were generally consistent from upstream to downstream. The most noticeable fluctuation occurred between sample locations UT100D and UT100C2, where the median pH value decreased from about 7.0 to roughly 6.8. Further downstream, median pH values slowly increased and returned to a median value of about 7.0 at station UT100B (Figure 9.1-91).

The pH values were variable across locations and months, and no patterns could be identified (Figure 9.1-110).

Total Suspended Solids. TSS showed relatively consistent concentrations throughout the Upper Talarik Creek sampling locations, indicating no localized sources of TSS across the sampling locations (Figure 9.1-92).

The stacked bar graph (Figure 9.1-111) exhibits a pattern generally opposite that of TDS. Highest median concentrations generally occurred in April, and the trend is more apparent in downstream than in

upstream locations. TSS is consistently low across locations in other months, with the exceptions of stations UT100A, and UT100C2, which exhibit later peaks apparent in late summer.

Major Ions

Evaluation of the temporal line graphs revealed several general trends, but differences were evident among constituents. Location UT146A, located within the deposit area, demonstrated the highest median concentrations across locations and had seasonal peaks in winter, summer, and fall.

Sodium. Sodium concentrations showed a decrease in median concentrations in the downstream direction (Figure 9.1-93). The median concentration for sodium was much higher at locations UT100D and UT100E than at all other locations. These locations are in or very near to the general deposit area. Sodium concentrations declined more gradually in the locations downstream.

The graph shown in Figure 9.1-112 indicates that generally consistent concentrations are present at most locations and months for sodium. Sodium concentrations at most locations were lower in April and May relative to the rest of the year, likely as a result of dilution from snowmelt. This trend is less apparent at sampling locations well downstream. May was the only month in which sodium was detected at tributary location UT135B, which was only sampled in May 2004. Because this tributary was only sampled in May 2004, it is of limited value in evaluating trends.

Potassium. Potassium showed a significant trend from upstream to downstream. Potassium concentrations decreased in the downstream direction, which was opposite to streamflow (Figure 9.1-94). Potassium-bearing deposits may be more isolated and/or correlated with the location of the general deposit area, which is closest to the upstream river locations. This would result in higher potassium concentrations in the upstream locations, followed by dilution as the source contribution decreased and streamflow increased.

In general, potassium concentrations peak in spring and are otherwise somewhat variable. Unlike many of the other constituents, the general trend is more apparent in downstream samples. Not only is the trend less apparent in upstream locations, it is actually reversed at tributary location UT146A, located just east of the general deposit area, where the concentration dips in the spring relative to other months (Appendix 9.1F). Concentrations were typically highest at station UT146A, located upstream just north of the general deposit area (Figure 9.1-113). Therefore, potassium input into the system appears to be influenced by the higher mineralization in the general deposit area.

Total Alkalinity. Total alkalinity exhibited higher median values at the two most upstream locations, UT100E and UT100D, both of which are associated with the deposit area (Figure 9.1-95). The median values became substantially lower downstream at stations, UT100C2, and UT100C1, and remained lower in locations further downstream. This is likely attributed to dilution from the deposit area as additional water enters the system downstream of the deposit.

Alkalinity was at its lowest in spring during snowmelt. The trend is somewhat less evident at downstream locations. Otherwise concentrations are generally consistent across the year for most stations (Figure 9.1-114).

Sulfate. Sulfate concentrations showed a general decrease in the downstream direction, although the median concentration increased slightly at the most downstream sample location (Figure 9.1-96). The

median sulfate concentrations were much higher at locations UT100D and UT100E than at all other locations. These locations are in or very near the deposit area. Sulfate concentrations are generally consistent but much lower at downstream locations.

Sulfate concentrations were consistent and low at most locations, with the exception of some concentrations detected in and near the general deposit area. Sulfate concentrations were lowest in April and May for most stations relative to other months but were always higher at station UT146A than at other locations (Figure 9.1-115).Location UT146A is a tributary located within the general deposit area, which exhibited a bimodal pattern where concentrations are higher in winter and summer and lower in spring and fall.

Chloride. Chloride increased in concentration from upstream to downstream, but the trend is not as clear as for other constituents because concentrations declined between stations UT100C2 and UT100C before increasing to the highest median at the furthest downstream location,UT100B (Figure 9.1-97).

Chloride median concentrations are generally bimodal, with peaks in spring and fall and troughs in summer and winter. The highest concentrations were in the fall for most locations, and overall concentrations were lowest in summer (Figure 9.1-116).

Fluoride. The fluoride median concentrations were below MRLs in all months; the streamflow graph illustrates variability in detection limits across months and locations (Figure 9.1-117).

Hardness (Unfiltered). Unfiltered hardness exhibited higher median values at the two most upstream locations, UT100E and UT100D, both of which are associated with the general deposit area (Figure 9.1-98). The median value was substantially lower at the next downstream location, UT100C2, and remained lower in all sample locations further downstream. This is likely attributed to dilution from the general deposit area as additional water enters the system downstream of the deposit.

A clear temporal pattern was observed for hardness, with lower concentrations in spring (associated with snowmelt) than in other seasons. This pattern was less evident in downstream sampling locations. (Figure 9.1-118).

Nutrients

Total Nitrate+Nitrite (as N). Total nitrate+nitrite (as N) showed generally consistent concentrations across main stem sampling locations, with no correlation to streamflow volume (Figure 9.1-99).

Total nitrate+nitrite (as N) was variable in median concentrations both by month and location, with many medians near the MRL (Figure 9.1-119). The highest median concentration occurred in October at station UT135A, and the next highest medians occurred in January at stations UT100C1 and UT100C2. Concentrations were generally lowest in summer.

Phosphorus. Phosphorus showed variable but slightly decreasing concentrations across main stem sampling locations, from upstream to downstream (Figure 9.1-100).

Phosphorus was at detectable concentrations all months at most locations, and no general trend could be identified. (Figure 9.1-120) Median concentrations of phosphorus were often below MRLs, indicating that many data points represent estimated concentrations.

Cyclical seasonal differences were apparent at several locations (UT100D, UT100C2, UT135A, and UT100A) with peaks in spring, summer, and fall. However, at most locations, median concentrations were higher only in spring or fall.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any samples. As a result, no graphs are presented.

Total Trace Elements

Evaluation of the temporal line graphs revealed several general trends, although differences by location were apparent in most cases.

Differences in temporal trends among elements may be related to differences in solubility, affinity for binding with organic matter, and/or proximity to mineralized locations. Peaks observed in the winter months (November through February) may be attributed to lower water volume; if only a small volume of water remains unfrozen during this time, this may drive concentrations up in winter. The high concentrations of some elements observed in spring (March through May) could be in association with snow or ice melting, when elements may be introduced to the main river stem and tributaries by runoff from terrestrial sources throughout the system.

Concentration peaks observed in late summer and fall months (August through October) are likely related to increased precipitation during these months and the resulting transport of elements to the river system through storm water runoff. In addition to increasing transport from terrestrial sources, both snowmelt and precipitation are also likely to result in increased water volume and velocity, which may also facilitate uptake of elements into the water column.

Iron. Iron exhibited a maximum median concentration at station UT100D that steadily declined at further downstream locations (Figure 9.1-101). This trend was not significant because the most upstream location, UT100E, had the lowest iron median concentration. This location is north of the general deposit area; therefore, this location is expected to have lower iron levels because it is outside the mineralized zone.

The stacked bar graph in Figure 9.1-121 indicates somewhat variable concentrations are present at most locations and months for iron.

Iron generally displays a bimodal trend, with higher concentrations in spring and fall and lower concentrations in summer and winter months. Concentrations at most stations are generally lowest in winter months. At station UT100C2 the fall peak is much higher than the spring peak; the opposite is the case for the furthest two downstream locations (UT100B and UT100A).

Copper. Copper exhibited a maximum median concentration at UT100D, which is the nearest downstream main stem sampling location to the general deposit area. Median concentrations generally declined at further downstream main stem sampling locations (Figure 9.1-102). The lowest median concentration was at station UT100E, the furthest upstream location, which is north of the general deposit location. Therefore, this location is expected to have lower copper levels because it is outside of the mineralized zone.

Copper concentrations are generally consistently low across months and locations, with one notable exception. Station UT100C2 had a concentration 4 to 5 times greater in February than in other months.

Station UT146A, located in the general deposit area, had a consistently higher copper concentration year-round than any other sampling location in the Upper Talarik Creek (Figure 9.1-122).

Zinc. Zinc showed no clear trend with distance downstream, but median concentrations were slightly lower at stations below station UT100C2 (Figure 9.1-103).

Zinc median concentrations across months and locations are somewhat variable but exhibit a few patterns. Zinc concentrations generally exhibit peaks in winter and summer but are not typically a function of distance from the general deposit area. Higher concentrations occur in February and July for several locations, and lower concentrations for most stations occur in November and December (Figure 9.1-123). February and July median concentrations are exceptionally high at multiple locations in each month. For February, higher median concentrations are present at stations UT100B and UT100C2, while in July, higher median concentrations were apparent at stations UT100D, UT135A, and UT141A. The latter locations are near or in the deposit area, while station UT100C2 is the next downstream location from the confluence of the creek and the tributary where station UT141A is located.

Lead. Lead showed no clear trend with distance downstream (Figure 9.1-104). Median lead concentrations were near or below the MRL at most locations.

Lead concentrations are highly variable across stations and months, with many stations having no detectable concentration much of the time. (Figure 9.1-124). Lead concentrations were typically consistently low; those locations with detectable median concentrations generally had modest peaks in winter, particularly at station UT119B, which is a tributary located approximately 5 miles south of the general deposit area. Station UT138A dominates the overall median in October. The months of February and June have the most stations with detectable lead concentrations.

Given the various locations and variation in detectable lead concentrations, sources of lead appear to be localized throughout the Upper Talarik Creek and not specifically related to the general deposit area.

Cadmium. Two of the three locations with detected cadmium concentrations had medians below MRLs. Therefore, the apparent trend of declining concentrations with distance downstream (Figure 9.1-105) is likely artificial due to lack of confidence in estimating concentrations around the MRL.

Cadmium was only sporadically detected, and the temporal line graphs in Appendix F are incomplete as a result. As shown in the stacked bar graph, cadmium concentrations are detectable at the most stations between January and May (Figure 9.1-125). Station UT100E, located just north of the deposit area, provides the highest median concentration of cadmium in June, and station UT138A, located east of the general deposit area, exhibits the highest concentration in February. This latter concentration was the highest median across all months and locations for cadmium. The stacked bar graph indicates it is likely cadmium concentrations appear to be, at least in part, influenced by the deposit area (Figure 9.1-125).

Arsenic. Arsenic showed a significant trend from upstream to downstream. Arsenic increased in concentration from below MRLs upstream to consistently higher medians above the MRLs downstream of station UT100D (Figure 9.1-106).

Arsenic median concentrations were generally below MRLs in all months at upstream sampling locations. Further downstream, detectable median concentrations are more often observed, with lowest concentrations in summer and winter. The stacked bar graph in Figure 9.1-126 indicates arsenic concentrations above MRLs are primarily associated with stations UT135A, UT119A, UT100C, UT100B, and UT100A. Across all months, the highest concentrations of arsenic were consistently found at two locations, UT135A and UT119A. These tributaries are approximately 5 miles east and 10 miles south of the general deposit area, respectively, so the higher concentrations of arsenic at these locations do not appear to be associated with the general deposit area.

Nickel. Nickel exhibited a maximum median concentration at station UT100D (Figure 9.1-107). The median concentration rapidly declined at station UT100C2 and remained fairly consistent further downstream.

Nickel median concentrations are consistently low across months and locations, with the exception of station UT146A, a tributary located within the deposit area (Figure 9.1-127). This location had the highest median nickel concentration in each month. This location showed a bimodal pattern with high concentrations in winter and summer and lower concentrations in spring and fall (Appendix F). Overall, medians are generally lower in spring than in other seasons. Nickel concentrations appear to be influenced by the general deposit area in Upper Talarik Creek water samples.

Molybdenum. Molybdenum showed a clear and significant trend from upstream to downstream. Molybdenum median concentrations increase from upstream to downstream (Figure 9.1-108).

The stacked bar graph in Figure 9.1-128 indicates relatively consistent concentrations are present at most locations and months for molybdenum. Molybdenum concentrations demonstrate a similar bimodal pattern to that described for zinc, with higher concentrations tending to occur in winter and summer months. Molybdenum generally has lower medians in April and May when streamflow is highest.

Cyanides

Total Cyanide. The total cyanide median concentrations were below MRLs at all locations, indicating the majority of data points reflect estimated concentrations. As a result, no meaningful interpretations could be drawn from the data, and no streamflow graph was prepared.

Total cyanide median concentrations were mostly below MRLs. Concentrations tended to be highest, and often exceeded MRLs, in summer, when multiple locations exhibited the highest median concentrations. This is particularly true at tributary stations UT135A and UT141A, located near the deposit area. A few detectable medians are apparent in the stacked bar graph for total cyanide (Figure 9.1-129). The highest concentrations of total cyanide occur in June for tributary location UT135A in the general deposit area and in August at tributary location UT141A, just east of the deposit area. Sources other than the deposit area appear to contribute to the naturally occurring concentrations of total cyanide detected in the Upper Talarik Creek drainage. One possibility is generation by cyanogenic bacteria (a genus of which is known to occur in the Lake Clark area), or cyanogenic plants, which would conform to an initial growing season in June and extend through August. Given the variety of locations where total cyanide was detected, it appears localized sources are present within the drainage

WAD Cyanide. The WAD cyanide median concentrations were below MRLs at all locations, indicating the majority of data points reflect estimated concentrations. As a result, no meaningful interpretations could be drawn from the data and no streamflow graph was prepared.

WAD cyanide exhibits a similar pattern to that of total cyanide, with location UT141A in August having the highest median concentration of this constituent within a given month and location. Station UT135A in June has the second highest median value (Figure 9.1-130). This is consistent with results obtained for total cyanide. June and August also represent the two months with the most stations exhibiting detectable WAD cyanide.

9.1.8.4. Results and Discussion: Kaskanak Creek

This section presents the findings of the surface water quality study at one location in Kaskanak Creek. Kaskanak Creek was included in this study to confirm it has no hydrological connection to the deposit drainage area. Surface water samples and measurement of physical and chemical parameters were obtained from the creek to assess the background concentrations and temporal variability of field and physical parameters, major ions, nutrients, trace elements, and cyanides. The analysis was conducted using data acquired during the 5-year period from 2004 to 2008.

The Kaskanak Creek study area encompasses a single sampling location (KC100A), approximately 20 miles southwest of the deposit area (Figure 9.1-3), 6 miles south of the North Fork Koktuli River, and 16 miles west of Upper Talarik Creek. Since objectives differed between Kaskanak Creek and rivers in the other three drainages, the number of sampling locations also differed. There was only one sampling location in Kaskanak Creek, compared to 7to 18 locations in the other three river drainages. As a result, statistics, particularly range and CVs, are not directly comparable between Kaskanak Creek and the other three drainages.

As shown in Table 9.1-8, 41 surface water samples were collected and analyzed from one sampling location in Kaskanak Creek between 2004 and 2008. The number of data points differs among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction. Others were analyzed only in some seasons (e.g., phosphorus, total orthophosphate), resulting in fewer data points as well.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, cyanides, and organic compounds.

Field and Physical Parameters

Eight field and physical parameters were measured in Kaskanak Creek surface water samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-8. Data for other analyzed parameters in this group can be found in Appendix 9.1B. The overall CV for this group of 0.81 is consistent with that of the other evaluated rivers.

Total Dissolved Solids. TDS is low relative to rivers in more-developed areas, with a mean concentration of 44.3 mg/L, which is similar to that of the South Fork Koktuli River and between the North Fork Koktuli River and Upper Talarik Creeks in concentration. The CV for TDS was 0.31.

pH (Field). The mean pH in Kaskanak Creek water samples was 6.67. The CV for pH was 0.08. A pH median of 6.61 indicates the water is slightly acidic, and more acidic than the other three river systems.

Dissolved Oxygen. DO was detected at a mean concentration of 10.3 mg/L, which is essentially the same as the other river systems. The CV for DO was 0.21.

Water Temperature. The mean water temperature was 4.19^{o}C. The CV for water temperature was 0.96. Water temperature is cold, with a median temperature of 3.14^{o}C. This is a higher median than the other three river systems.

Specific Conductivity (Field). The FOD for specific conductivity was 98 percent. The mean concentration for specific conductivity was 47.4 uS/cm, which is the same as the North Fork Koktuli River mean, but below the means of the South Fork Koktuli River and Upper Talarik Creek samples. The CV for specific conductivity was 0.24.

Turbidity. Turbidity is higher in Kaskanak Creek than in the other three rivers, as indicated by the mean concentration of 2.55 NTU. The CV for turbidity was 1.38.

Total Suspended Solids. TSS was detected in all samples at a mean concentration of 5.01 mg/L. The TSS mean concentration is more than twice the mean concentrations in the other three evaluated rivers. The CV for TSS was 1.45.

Oxidation Reduction Potential. ORP was detected in all samples at a mean concentration of 93 mV, with a range of -162 to 282 mV. This mean is slightly lower than those from the other three rivers. The CV for ORP was 1.08.

Major Ions

Kaskanak Creek surface water data for nine parameters (calcium, magnesium, sodium, and potassium, [total and dissolved], as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-8. Data for the other analyzed parameters in this group (e.g., total acidity and ion balance) can be found in Appendix 9.1B.

All major ions, except alkalinity (98 percent FOD) and fluoride (73 percent FOD), were detected in all samples. Calcium and sodium were detected at the highest mean concentrations of the individual ions in this group of constituents, while fluoride had a mean concentration one to two orders of magnitude lower than the other major ions (Table 9.1-8).

The overall CV for major ions was 0.25, which is lower than the CV for major ions in the three other river systems.

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 5.28 mg/L, which is the most abundant major ion in Kaskanak Creek samples. The CV for total calcium was 0.21.

Calcium (Dissolved). Dissolved calcium was detected at a mean concentration of 5.25 mg/L. The CV for dissolved calcium was 0.23.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 1.36 mg/L, which makes it the third most abundant major ion in Kaskanak Creek samples. The CV for total magnesium was 0.20.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 1.35 mg/L. The CV for dissolved magnesium was 0.22.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.58 mg/L, making it the second most abundant major ion in surface water samples from Kaskanak Creek. The CV for total sodium was 0.18.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.58 mg/L. The CV for dissolved sodium was 0.18. Total and dissolved sodium had almost identical concentrations.

Potassium (Total). Total potassium was detected in all samples at a mean concentration of 0.48 mg/L. The CV for total potassium was 0.24.

Potassium (Dissolved). Dissolved potassium was detected in all samples at a mean concentration of 0.48 mg/L. The CV for dissolved potassium was 0.21.

Alkalinity, Total. The FOD for total alkalinity was 98 percent. Total alkalinity was detected at a mean concentration of 22.3 mg/L, which is lower than the mean concentration in the North Fork Koktuli River. The CV for total alkalinity was 0.28.

Sulfate. Sulfate was detected in all samples at a mean concentration of 1.53 mg/L, which is lower than the mean in the other three river systems. The CV for sulfate was 0.28.

Chloride. Chloride was detected in all samples at a mean concentration of 0.99 mg/L, which is higher than in the other three river systems. The CV for chloride was 0.17.

Fluoride. The FOD for fluoride was 73 percent. Fluoride was detected at a mean concentration of 0.04 mg/L, which is below the MRLs but above the MDLs. The CV for fluoride was 0.49.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected in all samples at a mean concentration of 18.8 mg/L. The CV for hardness as $CaCO_3$ (not filtered) was 0.21. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria and is a bit softer than the water from the other three rivers.

Hardness as $CaCO_3$ (Filtered). Hardness as $CaCO_3$ (filtered) was detected in all samples at a mean concentration of 17.1 mg/L. The CV for hardness as $CaCO_3$ (filtered) was 0.34. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-8. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1B.

Nutrients were not detected in all samples. Total nitrate+nitrite (as N) was detected in 87 percent of surface water samples, phosphorus was detected in 85 percent of samples, and nitrogen, total ammonia (as N) was detected in only 24 percent of samples. Total orthophosphate [as P] was not detected in any of the water samples from Kaskanak Creek.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.62 (total phosphorus) to 1.58 (total nitrate+nitrite). The CV for all nutrients was 0.98.

Nitrogen, Total Ammonia (as N). The FOD for total ammonia (as N) was 24 percent. Nitrogen, total ammonia (as N) was detected at a mean concentration of 0.036 mg/L, which is below the MRLs but above the MDLs. The CV for nitrogen, total ammonia (as N) was 0.74.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 87 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.24 mg/L. The CV for total nitrate+nitrite (as N) was 1.58, representing one of the higher CVs of constituents for river water in this system.

Phosphorus. The FOD for phosphorus was 85 percent. Phosphorus was detected at a mean concentration of 0.041 mg/L, which is within the range of MDLs. The mean is, in part, a function of detection limits and estimated values. The CV for phosphorus was 0.62.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any Kaskanak Creek samples.

Total Trace Elements

Data for total aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-8 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1B.

Total barium, iron, arsenic, and manganese were detected in all samples, with three other trace elements (aluminum, copper, and molybdenum) present in 98 percent of samples. Total cadmium was detected in only four samples (FOD of 10 percent). Total iron was detected at much higher concentrations than other trace elements, with a mean concentration of 0.63 mg/L. All other total trace elements had mean concentrations that were one to four orders of magnitude lower, ranging from 0.091 mg/L for aluminum to 0.000014 mg/L for cadmium.

The overall CV for total trace elements in Kaskanak Creek surface water samples was 0.99. The overall CV was lower than in the other river systems, likely due in part to the presence of only a single sample location in Kaskanak Creek.

Aluminum. The FOD for total aluminum was 98 percent. Aluminum was detected at a mean concentration of 0.091 mg/L, which is the second most abundant trace element in Kaskanak Creek. The CV for total aluminum was 2.05, indicating relatively high variability across sampling dates.

Barium. Total barium was present in all samples at a mean concentration of 0.0021 mg/L. The CV for total barium was 0.73.

Iron. Total iron was present in all samples at a mean concentration of 0.63 mg/L and was the most abundant trace element in Kaskanak Creek river water samples. The CV for total iron was 0.94.

Copper. The FOD for total copper was 98 percent. Copper was detected at a mean concentration of 0.00029 mg/L, which is just above MRLs. The CV for total copper was 0.66, which is lower than for river samples in the other river systems.

Zinc. The FOD for total zinc was 68 percent. Zinc was detected at a mean concentration of 0.002 mg/L. The CV for total zinc was 1.1.

Lead. The FOD for total lead was 37 percent. Lead was detected at a mean concentration of 0.00016 mg/L, which is within the range of MRLs. The CV for total lead was 2.23, which indicates relatively high variability for this constituent in this system.

Cadmium. The FOD for total cadmium was 10 percent. Cadmium was detected at a mean concentration of 0.000014 mg/L, which is below MRLs and within the range of MDLs. Therefore, the mean concentration is largely a function of detection limits and estimated values. The CV for total cadmium was 1.0.

Arsenic. Total arsenic was present in all samples at a mean concentration of 0.0018 mg/L. The CV for total arsenic was 0.55.

Nickel. The FOD for total nickel was 63 percent. Nickel was detected at a mean concentration of 0.00022 mg/L. The CV for total nickel was 0.58.

Molybdenum. The FOD for total molybdenum was 98 percent. Molybdenum was detected at a mean concentration of 0.00036 mg/L. The CV for total molybdenum was 0.3, indicating low variability in concentrations in this creek.

Manganese. Total manganese was present in all samples at a mean concentration of 0.017 mg/L, making it the third most abundant trace element for river water samples in this system. The CV for total manganese was 0.69.

Dissolved Trace Elements

Data for dissolved aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-8 and discussed below. Other dissolved trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, selenium, silicon, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1B.

Dissolved barium, iron, and manganese were detected in all samples, with four other trace elements (aluminum, copper, arsenic, and molybdenum) present in at least 90 percent of samples. Dissolved cadmium was detected in the fewest samples, with only one detected concentration (2 percent FOD). Dissolved iron was detected at the highest concentration, with a mean concentration of 0.25 mg/L. All other dissolved trace elements had mean concentrations that were one to four orders of magnitude lower, ranging from 0.022 mg/L for aluminum to 0.000011 mg/L for cadmium.

The overall CV for dissolved trace element concentrations in Kaskanak Creek surface water samples was 0.51. This overall CV was lower than in the other river systems, likely due in part to the presence of only a single sample location in Kaskanak Creek.

Aluminum. The FOD for dissolved aluminum was 90 percent. Aluminum was detected at a mean concentration of 0.022 mg/L, which is within the range of MRLs for this trace element. Aluminum is the second most abundant dissolved trace element for river water samples in the system. The dissolved mean is about 4 times lower than the total mean for aluminum. The CV for dissolved aluminum was 0.8.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0017 mg/L. The CV for dissolved barium was 0.18, which indicates low variability for this constituent.

Iron. Dissolved iron was detected in all samples at a mean concentration of 0.25 mg/L. Iron was the most abundant dissolved trace element in Kaskanak Creek water samples. The CV for dissolved iron was 0.42.

Copper. The FOD for dissolved copper was 96 percent. Copper was detected at a mean concentration of 0.00027 mg/L. The CV for dissolved copper was 0.35.

Zinc. The FOD for dissolved zinc was 71 percent. Zinc was detected at a mean concentration of 0.0022 mg/L. The CV for dissolved zinc was 1.13.

Lead. The FOD for dissolved lead was 31 percent. Lead was detected at a mean concentration of 0.000068 mg/L. The CV for dissolved lead was 0.87, which is less than half the CV of total lead.

Cadmium. Dissolved cadmium was detected in only one sample (2 percent FOD). Cadmium was detected at a mean concentration of 0.000011 mg/L, which is a function of detection limits. The CV for dissolved cadmium was 0.54.

Arsenic. The FOD for dissolved arsenic was 98 percent. Arsenic was detected at a mean concentration of 0.0011 mg/L. The CV for dissolved arsenic was 0.3.

Nickel. The FOD for dissolved nickel was 88 percent. Nickel was detected at a mean concentration of 0.00029 mg/L. The CV for dissolved nickel was 0.39.

Molybdenum. The FOD for dissolved molybdenum was 97 percent. Molybdenum was detected at a mean concentration of 0.00036 mg/L. The CV for dissolved molybdenum was 0.33.

Manganese. Dissolved manganese was detected in all samples and had a mean concentration of 0.012 mg/L, making it the third most abundant dissolved metal for river water samples in the system. The CV for dissolved manganese was 0.26, indicating low variability of concentrations over time.

Cyanides

Total Cyanide. The FOD for total cyanide was 15 percent. Total cyanide was detected at a mean concentration of 0.0028 mg/L, which is below the MRL and above MDLs. Therefore, the mean concentration primarily reflects detection limits and estimated values. The CV for total cyanide was 3.26, which indicates high variability in this constituent concentration.

WAD Cyanide. WAD cyanide was detected in only two samples (5 percent FOD). WAD cyanide was detected at a mean concentration of 0.0024 mg/L, which is below the MRL and within MDLs. Therefore, the mean concentration reflects detection limits and estimated values. The CV for WAD cyanide was 3.38, which indicates high variability in this constituent concentration.

Organic Compounds

Dissolved organic carbon was the only organic compound analyzed in Kaskanak Creek samples.

Dissolved Organic Carbon. As shown in Table 9.1-8, dissolved organic carbon was detected in all samples at a mean concentration of 2.0 mg/L. The CV was 0.40, with concentrations ranging from 0.89 to 3.25 mg/L.

Comparison with Water Quality Criteria

Trace element concentrations were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison is presented in Table 9.1-19. Concentrations of most constituents were within water quality criteria. Concentrations were outside the most stringent criteria in at least one sample for the following constituents:

- pH was outside the criteria range in 15 out of 41 samples.
- Dissolved oxygen was below the minimum criteria in 1 of 29 samples.
- Alkalinity was below the minimum criteria in 9 of 43 samples.
- WAD cyanide was above the maximum criteria in 1 of 41 samples.

Because only one sample location is present at Kaskanak Creek, these concentrations above or below criteria ranges represent natural variability.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates. Concentrations were above the most stringent maximum criteria in at least one sample for the following trace elements:

- Aluminum (total: 7 of 41 samples).
- Cadmium (total: 1 of 41 samples).
- Iron (total: 2 of 41 samples).
- Lead (total: 4 of 41 samples; dissolved: 1 of 32 samples).

These represent between 3 percent and 18 percent of all samples for these trace elements. As for the constituents summarized above, these concentrations above the most stringent maximum criteria represent natural variability over time at the single sample location.

Temporal Trend Analysis

Surface water data from the single Kaskanak Creek sample location were grouped by month to evaluate potential seasonal trends in total analyte concentrations. Temporal line graphs (Figures 9.1-131 through 9.1-151) show median concentrations from January to December. Each of these groups of constituents is further discussed below.

Field and Physical Parameters

Total Dissolved Solids. TDS was variable across all months, with no identifiable pattern (Figure 9.1-131).

pH (Field). Median pH levels were consistent across all months; August and December had slightly higher pH values than other months (Figure 9.1-132).

Total Suspended Solids. TSS demonstrated high temporal variability. TSS exhibited the highest median concentration in April and May, with lowest median concentration in January (Figure 9.1-133). Concentrations generally decline throughout the summer until another increase in November. The higher spring concentrations are consistent with effects seen in the other river systems associated with snowmelt.

Major Ions

Sodium. Sodium concentrations were generally consistent across all months, except in the spring (April and May) when median concentrations are about 1/3 lower than in other months (Figure 9.1-134).

Potassium. Potassium concentrations increase slightly from January to their highest median in April (Figure 9.1-135). The lowest concentrations are observed in late spring and October, when snowmelt and rainfall events occur.

Alkalinity, Total. Alkalinity fluctuated seasonally, with lower median concentrations in the spring and (to a lesser extent) fall, relative to other months (Figure 9.1-136).

Sulfate. Sulfate concentrations demonstrate high variability across all months. Median concentrations are generally highest in winter, with additional peaks in June and fall (Figure 9.1-137).

Chloride. Chloride median concentrations are generally consistent across all months, although slightly lower in July (Figure 9.1-138).

Fluoride. Fluoride median concentrations were below MRLs in all months, so no figure was prepared.

Hardness as $CaCO_3$ (Not Filtered). Hardness concentrations were lowest in spring when snowmelt occurs and were relatively consistent the rest of the year (Figure 9.1-139).

Nutrients

Total Nitrate+Nitrite (as N). Total nitrate+nitrite (as N) had median concentrations above MRLs in January, May, and August (Figure 9.1-140). The median concentration in May was 3 times greater than in any other month.

Phosphorus. Phosphorus median concentrations were relatively consistent across months. With the exception of a peak in January that was substantially greater than any other month (Figure 9.1-141).

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected, so no figure was prepared.

Trace Elements

As shown in Figures 9.1-142 through 9.1-149, some trace elements had median concentrations below MRLs in at least one month. Of those trace elements with median concentrations above MRLs in all months, different patterns were observed for different trace elements, as discussed below.

Iron. Iron concentrations were highest in April but were also relatively high in mid through late summer. Lowest concentrations occurred in winter months (Figure 9.1-142).

Copper. Copper concentrations were variable but were highest in April, which was almost double the next highest concentration observed in February (Figure 9.1-143). Apparently, higher concentrations of copper in Kaskanak Creek are often strongly associated with increased erosion due to snowmelt but not particularly associated with fall rains.

Zinc. Median concentrations of zinc were higher in February and July relative to other months (Figure 9.1-144). These are among the lowest flow months for Kaskanak Creek and may represent concentrations of this relatively water soluble trace element during low flow.

Lead. Lead concentrations were at or below MRLs in most months. The highest median concentrations are evident in February and March (Figure 9.1-145).

Cadmium. Cadmium median concentrations were above MRLs only in March (Figure 9.1-146).

Arsenic. Arsenic median concentrations increased from January to April, declined in May, and then increased again through August before declining through the fall (Figure 9.1-147).

Nickel. Nickel concentrations were above MRLs in most months, but were lowest in winter (December and January) and highest in February (Figure 9.1-148). Concentrations declined slowly through the summer months.

Molybdenum. Molybdenum concentrations were variable, but overall lower concentrations were detected in April and May (Figure 9.1-149).

Cyanides

Total Cyanide. Total cyanide median concentrations were below MRLs in all months except August (Figure 9.1-150).

WAD Cyanide. WAD cyanide median concentrations were below MRLs in all months except August (Figure 9.1-151). As discussed earlier, this is consistent with the hypothesis that cyanide is produced by cyanogenic bacteria or plants during the short growing season in the region.

9.1.8.5. Comparison Across River Systems

Distributions and central tendencies of constituent concentrations were evaluated for significant differences among the North Fork Koktuli River, South Fork Koktuli River, Upper Talarik Creek, and

Kaskanak Creek river systems through the use of two nonparametric statistical tests. The same parameters included in the spatial and temporal evaluations were included in this analysis.

First, the Kruskal-Wallis (KW) test, a non-parametric version of the analysis of variance (ANOVA) test, was performed to identify chemical concentration differences among the four drainages. This test converts the concentrations across all river systems to numerical ranks, which are ordered by concentration regardless of river system. The resulting ranks from each system are then statistically compared for differences among the mean of the ranks. For this test, a significance level (i.e., probability value or p-value) of 0.1 was used as a cutoff to identify the parameters to be included in the pair-wise comparisons. A significant result for this test indicates at least one of the datasets is different from the others. This value was used rather than the more typical 0.05 p-value to ensure constituents with borderline pair-wise differences were not excluded from the second step of the evaluation.

For parameters with p-values of 0.1 or less resulting from the KW test, the Mann-Whitney U-Test, a non-parametric alternative to the *t*-test, was performed to identify pair-wise differences between each combination of waterbodies. This test is conducted similarly to the KW test, but compares only two datasets instead of multiple datasets. The standard p-value of 0.05 was used to identify constituents with significant differences in concentrations.

Results of these analyses are discussed below, first for the overall comparisons and then for the pair-wise comparisons. Specific locations were not compared across rivers; the focus of this evaluation was to compare concentrations across river systems rather than specific sampling stations. All of the drainages except for Kaskanak Creek are reasonably represented along their length, so this represents a valid comparison, particularly among the three primary drainages within the mine study area.

The KW test results are provided in Table 9.1-20, including the mean ranks for each river system and the relative sample count. These results indicate concentrations of most constituents significantly differ across drainages. Four of the evaluated field and physical parameters (TDS, pH, alkalinity, and TSS) were significantly different across river systems. Five major ions, including sodium, sulfate, chloride, fluoride, and hardness (as $CaCO_3$), and one nutrient (total nitrate+nitrite [as N]), also differed significantly across river systems. Of the trace elements evaluated, only two (cadmium and lead) had p-values greater than 0.1 based on this comparison (0.72 and 0.69, respectively). All others were significantly different across river systems. These differences were anticipated given the differences in surficial and subsurface geology among drainages. Each of these significant differences was further compared in the Mann-Whitney U-Test, as described below.

The parameters identified above as significantly different, based on the KW test results, were included in the pair-wise Mann-Whitney U-Test. Significant differences between at least two pairs were identified for all parameters included in the pair-wise tests (Table 9.1-21). TSS, sulfate, alkalinity, arsenic, and molybdenum concentrations were significantly different between all six pairs of drainages. Copper and potassium concentrations differed significantly between all pairs except for the North Fork Koktuli River and Upper Talarik Creek drainages, while iron and chloride concentrations differed significantly between all pairs except the South Fork Koktuli River and Upper Talarik Creek. Sodium concentrations differed significantly between all river systems except Upper Talarik Creek and Kaskanak Creek. Nickel and hardness concentrations were each significantly different between four pairs of river drainages, pH differed significantly between three pairs, and zinc differed significantly between two pairs of river drainages. Detailed results of the pair-wise analysis are provided in Table 9.1-21. Box and whisker plots

for individual constituents comparing concentrations in the different river systems are provided in Appendix 9.1G.

These findings are primarily explained by the proximity of South Fork Koktuli River and Upper Talarik Creek sampling locations to the deposit area. The relative ranks (i.e., highest to lowest concentrations) for each waterbody differed by analyte. Sulfate, copper, zinc, nickel, and molybdenum concentrations were greatest in the South Fork Koktuli River, consistent with the headwaters of this river passing through the deposit area and multiple sample locations present in this area. TDS, pH, sodium, alkalinity, hardness, nitrogen (total nitrate+nitrite [as N]), and nickel concentrations were greatest in the Upper Talarik Creek drainage. Significantly higher concentrations of copper, molybdenum, nickel, zinc, and sulfate were also present in the South Fork Koktuli River than in the North Fork Koktuli River, consistent with its proximity to the deposit area.

These results indicate that, while concentrations of parameters most closely associated with the general deposit area are higher in the South Fork Koktuli River, the Upper Talarik Creek drainage receives substantial input of dissolved concentrations, primarily of sodium and nitrogen-nitrate (as N), leading to higher overall concentrations in the Upper Talarik Creek relative to the other evaluated river systems.

TSS, potassium, chloride, iron, and arsenic concentrations were highest in Kaskanak Creek, while cadmium and lead concentrations were highest in the North Fork Koktuli River drainage. This most likely indicates these parameters are unrelated to the general deposit area and represent different signatures than the other drainage areas. These differences are also apparent through evaluation of the piper plots for rivers provided in Appendix 9.1H.

Based on this evaluation, it is clear that each of the major river systems has significantly different constituent background concentrations, and many constituents vary in concentration both seasonally and across locations.

9.1.9. Seeps

This section presents the findings of the water quality study of seeps located in the mine study area. Water samples and measurement of physical and chemical parameters were obtained from seeps to assess spatial and temporal variability in the mine study area. The analysis was conducted using data acquired during the 5-year period from 2004 to 2008. Six hundred forty eight samples were analyzed for NOCs over the 5-year period in the North Fork Koktuli, South Fork Koktuli, and Upper Talarik drainages (Table 9.1-22). No seeps were evaluated in the Kaskanak Creek drainage.

9.1.9.1. Results and Discussion: North Fork Koktuli Seeps

This section presents the findings of the water quality study of seeps in the North Fork Koktuli River drainage. As shown in Table 9.1-23, 104 seep water samples were inventoried between 2004 and 2008 from the North Fork Koktuli River drainage. The number of data points differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.0.

Field and Physical Parameters

Eight field and physical parameters were measured in North Fork Koktuli River drainage seep samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP.

Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-23. The overall CV for this group of 0.87 is similar to that of North Fork Koktuli River water samples (0.81).

Total Dissolved Solids. The FOD for TDS was 95 percent. TDS was detected at a mean concentration of 34.6 mg/L. The CV for TDS was 0.68.

pH (Field). The mean concentration for pH was 6.27. The CV for pH was 0.092. A pH median of 6.31 indicates the seep water is slightly acidic, and slightly more acidic than median pH values in all evaluated rivers in this study.

Dissolved Oxygen. DO was detected at a mean concentration of 8.97 mg/L, which is lower than DO in all evaluated rivers in this study. The CV for DO was 0.23.

Water Temperature. The mean water temperature was 3.38^{o}C. The CV for water temperature was 0.54. Water temperature is cold, but slightly warmer than the other evaluated rivers and creeks in this study, with a median temperature of 2.87^{o}C.

Specific Conductivity (Field). The mean specific conductivity was 42.9 uS/cm. The CV for specific conductivity was 0.73.

Turbidity. The mean concentration for turbidity was 0.32 NTU. The CV for turbidity was 1.79. Turbidity is lower in seeps than in evaluated rivers in this study, as indicated by the lower mean concentration. However, turbidity variability is high relative to other parameters in this group.

Total Suspended Solids. The FOD for TSS was 29 percent, which is lower than that for evaluated rivers in this study. TSS was detected at a mean concentration of 2.3 mg/L. The CV for TSS was 1.02.

Oxidation Reduction Potential. ORP was detected in all samples at a mean concentration of 172 mV, with a range of -65 to 286 mV. The CV for ORP was 0.41.

Major Ions

North Fork Koktuli seep data for nine parameters (calcium, magnesium, sodium, and potassium [total and dissolved], as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-23. Data for the other analyzed parameters in this group (e.g., total acidity and ion balance) can be found in Appendix 9.1I.

Calcium (total and dissolved), sodium (total and dissolved) and hardness as $CaCO_3$ (filtered) were detected in all samples. Chloride was detected in all but one sample (99.8 percent). Calcium, sulfate, and sodium (total and dissolved) were the individual ions detected at the highest mean concentrations. The overall CV for this group of 0.80 is twice the overall CV calculated for North Fork Koktuli River water samples (0.39), but is similar to seeps in other drainages (0.70 and 0.87 for Upper Talarik and South Fork Koktuli River, respectively).

Piper plots summarizing the major ionic distribution in the North Fork Koktuli drainage are provided in Appendix 9.1J. Box and whisker plots for each major ion are provided in Appendix 9.1K. These plots

indicate less variability than trace elements but slightly higher variability than major ions in the evaluated rivers in this study.

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 5.12 mg/L. The CV for total calcium was 0.79.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 5.52 mg/L. The CV for dissolved calcium was 0.72.

Magnesium (Total). The FOD for total magnesium was 95 percent. Magnesium was detected at a mean concentration of 1.11 mg/L. The CV for total magnesium was 1.30.

Magnesium (Dissolved). The FOD for dissolved magnesium was 97 percent. Magnesium was detected at a mean concentration of 1.26 mg/L. The CV for dissolved magnesium was 1.17.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.21 mg/L, making it the third most abundant major ion in North Fork Koktuli seeps. The CV for total sodium was 0.44.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.34 mg/L. The CV for dissolved sodium was 0.41.

Potassium (Total). The FOD for total potassium was 61 percent. Potassium was detected at a mean concentration of 0.43 mg/L. The CV for total potassium was 0.94.

Potassium (Dissolved). The FOD for dissolved potassium was 63 percent. Potassium was detected at a mean concentration of 0.46 mg/L. The CV for dissolved potassium was 0.86.

Alkalinity, Total. The FOD for total alkalinity was 93 percent. Total alkalinity was detected at a mean concentration of 19.2 mg/L. The CV for total alkalinity was 0.93.

Sulfate. The FOD for sulfate was 97 percent. Sulfate was detected at a mean concentration of 3.0 mg/L, making it the second most abundant major ion in North Fork Koktuli seeps. The CV for sulfate was 0.96.

Chloride. The FOD for chloride was 99.8 percent. Chloride was detected at a mean concentration of 0.84 mg/L. The CV for chloride was 0.84.

Fluoride. The FOD for fluoride was 37 percent. Fluoride was detected at a mean concentration of 0.048 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for fluoride was 0.33.

Hardness as CaCO3 (Filtered). Hardness as $CaCO_3$ (filtered) was detected in two samples at a mean concentration of 6.09 mg/L. The CV for hardness as $CaCO_3$ (filtered) was 0.63.

Hardness as CaCO3 (Not Filtered). The FOD for hardness as $CaCO_3$ (not filtered) was 97 percent. Hardness as $CaCO_3$ (not filtered) was detected at a mean concentration of 17.8 mg/L, or about 3 times greater than filtered hardness. The CV for hardness as $CaCO_3$ (not filtered) was 0.87. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-23. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1I.

Nutrients were not detected in all samples. Total nitrate+nitrite (as N) was detected in 98 percent of surface water samples, phosphorus was detected in 65 percent of samples, and nitrogen, total ammonia (as N) was detected in only 17 percent of samples. Total orthophosphate [as P] was not detected in any of the water samples from North Fork Koktuli drainage seeps.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.89 (total phosphorus) to 2.17 (total ammonia as N). The CV for all nutrients was 1.52, which is higher than the CV for nutrients in the evaluated rivers, and also higher than the CVs in seep samples from the South Fork Koktuli drainage and Upper Talarik drainage.

Nitrogen, Total Ammonia (as N). The FOD for nitrogen, total ammonia (as N) was 21 percent. Nitrogen, total ammonia (as N) was detected at a mean concentration of 0.077 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for nitrogen, total ammonia (as N) was 2.17, reflecting relatively high variability in this constituent.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 89 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.17 mg/L, which is within the range of MRLs, indicating the mean concentration is partially a function of estimated values and detection limits. The CV for total nitrate+nitrite (as N) was 1.50.

Phosphorus. The FOD for phosphorus was 75 percent. Phosphorus was detected at a mean concentration of 0.020, which is within the range of MRLs and MDLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for phosphorus was 0.89.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any seep sample from the North Fork Koktuli River drainage.

Total Trace Elements

North Fork Koktuli seep data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-23 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1I.

Trace elements were not detected in all seep samples from the North Fork Koktuli River drainage. Aluminum and barium were both detected in over 90 percent of samples, and cadmium was detected in only 10 percent of samples. Iron and aluminum were detected at the highest mean concentrations across the trace elements. Other trace metal mean concentrations were one to three orders of magnitude lower.

The overall CV for this group of 1.27 is less than the CV of 1.55 calculated for North Fork Koktuli River water samples, but much lower than the CV for seeps in other drainages (2.96 and 3.06 for South Fork Koktuli River and Upper Talarik Creek samples, respectively).

Aluminum. The FOD for total aluminum was 95 percent. Aluminum was detected at a mean concentration of 0.025 mg/L, making it the second most abundant total trace element in North Fork Koktuli seeps. The CV for total aluminum was 1.72, which is the third highest variability in this group.

Barium. The FOD for total barium was 91 percent. Barium was detected at a mean concentration of 0.0028 mg/L. The CV for total barium was 1.08.

Iron. The FOD for total iron was 62 percent. Iron was detected at a mean concentration of 0.052 mg/L, which represents the most abundant total trace element in North Fork Koktuli seeps. The CV for total iron was 2.44, which is the second highest variability across total trace elements in North Fork Koktuli seeps.

Copper. The FOD for total copper was 45 percent. Copper was detected at a mean concentration of 0.00037 mg/L. The CV for total copper was 1.14.

Zinc. The FOD for total zinc was 27 percent. Zinc was detected at a mean concentration of 0.0012 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for total zinc was 0.86.

Lead. The FOD for total lead was 19 percent. Lead was detected at a mean concentration of 0.000062 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total lead was 1.14.

Cadmium. The FOD for total cadmium was 10 percent. Cadmium was detected at a mean concentration of 0.000033 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total cadmium was 0.60.

Arsenic. The FOD for total arsenic was 19 percent. Arsenic was detected at a mean concentration of 0.00026 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total arsenic was 0.61.

Nickel. The FOD for total nickel was 33 percent. Nickel was detected at a mean concentration of 0.00026 mg/L, which is within the range of MRLs and MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total nickel was 0.48, which is the lowest variability across total trace elements in North Fork Koktuli seeps.

Molybdenum. The FOD for total molybdenum was 46 percent. Molybdenum was detected at a mean concentration of 0.00032 mg/L, which is within the range of MDLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for total molybdenum was 1.03.

Manganese. The FOD for total manganese was 64 percent. Manganese was detected at a mean concentration of 0.0014 mg/L. The CV for total manganese was 2.88, which represents the highest variability across total trace elements in North Fork Koktuli seeps.

Dissolved Trace Elements

North Fork Koktuli seep data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-23 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1I.

None of the trace elements were present above detection limits in all seep samples. Barium was detected in 95 percent of all samples. The FOD of the remaining dissolved trace elements in seep water samples ranged from 74 percent (aluminum) to 8 percent (cadmium). The mean concentrations of the dissolved trace elements were slightly above or considerably below 0.001 mg/L.

The overall CV for this group of 1.12 is less than the CV of 1.82 calculated for North Fork Koktuli River water samples, and much lower than the CV for seeps in other drainages (3.09 and 3.27 for South Fork Koktuli River and Upper Talarik Creek samples, respectively).

Aluminum. The FOD for dissolved aluminum was 74 percent. Aluminum was detected at a mean concentration of 0.0099 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved aluminum was 1.03.

Barium. The FOD for dissolved barium was 95 percent. Barium was detected at a mean concentration of 0.0041 mg/L, which is the third most abundant dissolved trace element in North Fork Koktuli seeps. The CV for dissolved barium was 0.90.

Iron. The FOD for dissolved iron was 52 percent. Iron was detected at a mean concentration of 0.021 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. Iron was detected at the highest mean concentration across dissolved trace elements. The CV for dissolved iron was 1.75, reflecting relatively high variability for this dissolved element.

Copper. The FOD for dissolved copper was 42 percent. Copper was detected at a mean concentration of 0.00031 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved copper was 0.52, the lowest variability across dissolved trace elements in North Fork Koktuli seeps.

Zinc. The FOD for dissolved zinc was 40 percent. Zinc was detected at a mean concentration of 0.0023 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved zinc was 0.74.

Lead. The FOD for dissolved lead was 23 percent. Lead was detected at a mean concentration of 0.000059 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for dissolved lead was 0.92.

Cadmium. The FOD for dissolved cadmium was 8 percent, the lowest across trace elements for North Fork Koktuli seeps. Cadmium was detected at a mean concentration of 0.000033 mg/L, which is below MRLs and within the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for dissolved cadmium was 0.61.

Arsenic. The FOD for dissolved arsenic was 14 percent. Arsenic was detected at a mean concentration of 0.00025 mg/L, which is within the range of MRLs and MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for dissolved arsenic was 0.68.

Nickel. The FOD for dissolved nickel was 43 percent. Nickel was detected at a mean concentration of 0.00039 mg/L, which is within the range of MRLs and MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for dissolved nickel was 0.83.

Molybdenum. The FOD for dissolved molybdenum was 48 percent. Molybdenum was detected at a mean concentration of 0.00033 mg/L, which is within the range of MRLs and MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for dissolved molybdenum was 1.03.

Manganese. The FOD for dissolved manganese was 56 percent. Manganese was detected at a mean concentration of 0.0011 mg/L. The CV for dissolved manganese was 3.32, which is the highest variability expressed in dissolved trace element concentrations for North Fork Koktuli seeps.

Cyanides

Total Cyanide. The FOD for total cyanide was 8 percent. Total cyanide was detected at a mean concentration of 0.0025 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total cyanide was 1.21.

WAD Cyanide. The FOD for WAD cyanide was 14 percent. WAD cyanide was detected at a mean concentration of 0.0023 mg/L, or slightly lower than that for total cyanide. The mean concentration is below MRLs and within the range of MDLs. The mean is primarily a function of detection limits and estimated values. The CV for WAD cyanide was 1.31.

Comparison with Water Quality Criteria

North Fork Koktuli seep field and physical parameters, ions, trace elements, and cyanide concentrations were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison is presented in Table 9.1-24. Concentrations of most constituents met water quality criteria. Concentrations were outside most stringent criteria in at least one sample for the following constituents:

- pH was outside the most stringent criteria range in 68 of 104 samples.
- DO was below the most stringent minimum criteria in 16 of 104 samples.
- Alkalinity was below the most stringent minimum criteria in 67 of 104 samples.
- WAD cyanide was above the most stringent maximum criteria in 4 of 103 samples.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness

values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates. Concentrations were above the most stringent maximum water quality criteria in at least one sample for the following trace elements:

- Aluminum (total: 6 in 104 samples).
- Cadmium (total: 21 of 104 samples; dissolved: 21 of 104 samples).
- Copper (total: 5 of 104 samples; dissolved: 3 of 88 samples).
- Iron (total: 1 of 104 samples).
- Lead (total: 11 of 104 samples; dissolved: 8 of 95).

These are the same constituents that also demonstrated naturally occurring concentrations above the most stringent maximum criteria in North Fork Koktuli River samples.

Spatial and Temporal Trend Analysis

Stacked bar graphs were prepared for each of the three drainages to show median analyte concentrations by seep location for each month. These graphs were prepared to identify the relative concentrations of specific constituents in each drainage; however, because not all seeps were sampled at the same time, this information cannot be gleaned from the graphs. The results of stacked bar graphs analysis for the subset of seeps evaluated in each drainage are presented below. Only constituents generally detected above MRLs were included in the following discussion.

Overall, very low concentrations of many constituents were present in seeps sampled in March and April from this drainage, and only from station SP57. Seep sampling station SP57 is located within an upwelling area in the floodplain of the North Fork Koktuli River; therefore, the concentrations in this seep may be influenced by surface water as well as groundwater. Concentrations increase for all chemicals and locations beginning in May, but different patterns are evident for different chemicals, as discussed below. Stacked bar graphs for the North Fork Koktuli River Drainage seeps are presented on Figures 9.1-152 through 9.1-168 and discussed by constituent below.

Field and Physical Parameters

Total Dissolved Solids. TDS is primarily detected in North Fork Koktuli seeps in late summer and fall and is well distributed across different seeps during that time period (Figure 9.1-152).

Total Suspended Solids. North Fork Koktuli seeps had detectable concentrations at different locations during different months. Of the seeps sampled, the highest concentrations of TSS occurred primarily in either August, October, or November. TSS was detected in the highest concentrations at stations SP99, SP113 and SP53. The latter two of these seeps are located in the general deposit area (Figure 9.1-153).

Major Ions

Sodium. Sodium shows a trend of increasing number of seeps showing detectable concentrations of sodium between May and October, with no single seep dominating input (Figure 9.1-154).

Potassium. Potassium has primary and steady concentrations at seep station SP57 in all months in which samples were collected, and additional contribution from other seeps in the summer and fall (Figure 9.1-155).

Alkalinity. Alkalinity shows a trend of increasing number of seeps with detectable alkalinity concentrations between May and November, with the highest concentration exhibited at station SP99 in November (Figure 9.1-156).

Sulfate. Sulfate follows a similar trend to that of sodium and alkalinity but generally has the highest concentrations at station SP53, except in the fall when stations SP44 and SP113 have similar contributions (Figure 9.1-157).

Chloride. Chloride shows a trend similar to sodium of increasing number of seeps exhibiting detectable concentrations between May and October, with no single seep exhibiting notably higher concentrations than the others (Figure 9.1-158).

Fluoride. Fluoride follows the trend of increasing number of seeps with detectable concentrations between spring and fall, and has detectable concentrations at station SP113 only in September (Figure 9.1-159).

Hardness as $CaCO_3$ (Unfiltered). Hardness is generally consistent across months where samples were collected at a given location but an increase in the number of seeps with detectable hardness occurs in late summer and fall months (Figure 9.1-160).

Nutrients

Total Nitrate+Nitrite (as N). Total nitrate+nitrite (as N) shows increasing number of seeps with detectable concentrations between June and November (Figure 9.1-161). Station SP100 has the highest median concentration in five of the seven months in which samples were collected, but the highest median concentration was at station SP53 in September.

Phosphorus. Phosphorus shows increasing number of seeps with detectable concentrations between June and November (Figure 9.1-162). The summer months had highest median concentrations at location SP44. In other months, primary contributions are from locations SP31 and SP53.

Trace Elemnts

Iron. Iron had contributions from stations SP99 and SP44 in summer and fall, providing the highest median concentrations in North Fork Koktuli seeps (Figure 9.1-163).

Copper. Copper had increasing numbers of seeps with detectable concentrations of copper in late summer, the highest concentrations were generally at station SP53, with exceptions of spikes at station SP100 in September and station SP99 in November (Figure 9.1-164).

Zinc. Zinc had detectable concentrations at the most North Fork Koktuli seeps in August, with the highest concentration at station SP31 in that month (Figure 9.1-165). Zinc was detectable most frequently at station SP53. Otherwise no trends were apparent for zinc.

Lead. Lead was seldom detected at more than one seep during a month with the exception of August and October. The highest concentrations occurred repeatedly at station SP53 (Figure 9.1-166).

Nickel. Nickel has detectable concentrations from seep station SP53 in all months in which samples were collected except March. Station SP57 shows generally increasing concentrations between June and November (Figure 9.1-167).

Molybdenum. Molybdenum is detectable at the greatest number of North Fork Koktuli seeps in the summer and fall, with the highest concentrations at seep SP99 in late summer and fall (Figure 9.1-168).

9.1.9.2. Results and Discussion: South Fork Koktuli Seeps

This section presents the findings of the water quality study of seeps in the South Fork Koktuli River drainage. As shown in Table 9.1-25, 206 seep water samples were collected and analyzed between 2004 and 2008 from the South Fork Koktuli River drainage. The number of data points differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction. Other constituents (e.g., phosphorus, total orthophosphate [as P]) were only analyzed in certain years and, as a result, have lower sample counts.

The following subsections discuss the South Fork Koktuli seeps summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, cyanides, and organic compounds.

Field and Physical Parameters

Eight field and physical parameters were measured in the South Fork Koktuli River drainage seep samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-25. The overall CV across all field and physical parameters was 1.00, which is higher than the CVs for seep samples from the North Fork Koktuli and Upper Talarik drainages.

Total Dissolved Solids. The FOD for TDS was 99 percent. TDS was detected at a mean concentration of 46.7 mg/L. The CV for TDS was 0.72.

pH (Field). The mean pH value was 6.02 and the CV was 0.16. A pH median of 6.22 indicates the seep water is slightly acidic and slightly lower than median pH values in rivers.

Dissolved Oxygen. DO was detected at a mean concentration of 9.40 mg/L. The CV for DO was 0.22, reflecting low variability in this constituent in South Fork Koktuli seeps.

Water Temperature. The mean water temperature was 3.44^{o}C. The CV for water temperature was 0.57. Water temperature is cold but slightly warmer than the evaluated rivers and creeks in this study, with a median temperature of 3.08^{o}C.

Specific Conductivity (Field). The mean specific conductivity was 63.7 uS/cm, which is about 50 percent higher than the mean in North Fork Koktuli seep samples, but lower than the mean in Upper Talarik seep samples. The CV for specific conductivity was 0.93.

Turbidity. The mean concentration for turbidity was 0.41 NTU. The CV for turbidity was 2.25. Turbidity is lower in seeps than in evaluated rivers, is slightly higher than in North Fork Koktuli seep samples, and is similar to the mean in Upper Talarik seep samples.

Total Suspended Solids. The FOD for TSS was 44 percent. TSS was detected at a mean concentration of 3.53 mg/L, which is about 50 percent higher than the mean in North Fork Koktuli seep samples and about 20 percent higher than the mean in Upper Talarik seep samples. The CV for TSS was 2.36, which is the highest variability across this group of constituents.

Oxidation Reduction Potential. ORP was detected in all samples at a mean concentration of 195 mV, with a range of -132 to 546 mV. The CV for ORP was 0.56.

Major Ions

South Fork Koktuli seep sample data for nine parameters (calcium, magnesium, sodium, and potassium [total and dissolved], as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-25. Data for the other analyzed parameters in this group (e.g., total acidity and ion balance) can be found in Appendix 9.1I.

Sodium (total and dissolved), chloride, and hardness as $CaCO_3$ (filtered) were detected in all samples. Calcium, magnesium, and sulfate were all detected in more than 95 percent of samples. Fluoride (48 percent FOD) was detected at the lowest frequency of major ions in South Fork Koktuli seep samples.

Sulfate (15.0 mg/L) had the highest concentration of individual major ions in South Fork Koktuli seep samples. Calcium, sodium, and magnesium also had mean concentrations above 1.0 mg/L.

Piper plots summarizing the major ionic distribution in the South Fork Koktuli drainage are provided in Appendix 9.1J. Box and whisker plots for each major ion are provided in Appendix 9.1K. These plots indicate higher variability than major ions in rivers. The overall CV across all major ions was 0.87, which is double the CV of major ions in Upper Talarik Creek water samples, but only slightly higher than the CVs for seep samples from the North Fork Koktuli and Upper Talarik drainages.

Calcium (Total). The FOD for total calcium was 99 percent. Calcium was detected at a mean concentration of 6.1 mg/L and represented the second most abundant major ion in South Fork Koktuli seep samples. The CV for total calcium was 0.67.

Calcium (Dissolved). The FOD for dissolved calcium was 99 percent. Calcium was detected at a mean concentration of 6.48 mg/L. The CV for dissolved calcium was 0.62.

Magnesium (Total). The FOD for total magnesium was 96 percent. Magnesium was detected at a mean concentration of 1.23 mg/L. The CV for total magnesium was 0.93.

Magnesium (Dissolved). The FOD for dissolved magnesium was 98 percent. Magnesium was detected at a mean concentration of 1.33 mg/L. The CV for dissolved magnesium was 0.86.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 1.94 mg/L, which is the third most abundant major ion in South Fork Koktuli seep samples. The CV for total sodium was 0.41.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.02 mg/L. The CV for dissolved sodium was 0.40.

Potassium (Total). The FOD for total potassium was 66 percent. Potassium was detected at a mean concentration of 0.53 mg/L. The CV for total potassium was 1.10.

Potassium (Dissolved). The FOD for dissolved potassium was 65 percent. Potassium was detected at a mean concentration of 0.54 mg/L. The CV for dissolved potassium was 1.11.

Alkalinity, Total. The FOD for total alkalinity was 80 percent. Total alkalinity was detected at a mean concentration of 12.3 mg/L, which is 50 percent lower than in North Fork Koktuli seep samples. The CV for total alkalinity was 0.88.

Sulfate. The FOD for sulfate was 97 percent. Sulfate was detected at a mean concentration of 15 mg/L, which is the highest concentration of the major ions in South Fork Koktuli seep samples. The mean concentration is 5 times that of North Fork Koktuli seeps and twice that of Upper Talarik seeps, likely due to the proximity of the South Fork Koktuli seeps to the general deposit area. The CV for sulfate was 1.82, which is the highest variability observed in seeps for major ions among the three drainages. This is expected because seeps in this drainage include both mineralized and non-mineralized locations.

Chloride. Chloride was detected in all samples at a mean concentration of 0.9 mg/L. The CV for chloride was 0.70.

Fluoride. The FOD for fluoride was 48 percent. Fluoride was detected at a mean concentration of 0.077 mg/L, which is below MRLs and in the range of MDLs. The mean is largely a function of detection limits and estimated values. The CV for fluoride was 1.10.

Hardness as $CaCO_3$ (Filtered). Hardness as $CaCO_3$ (filtered) was detected in all eight samples at a mean concentration of 22.4 mg/L, which is about 3.5 times higher than the mean in North Fork Koktuli drainage seep samples but slightly lower than the mean in Upper Talarik seep samples. The CV for hardness as $CaCO_3$ (filtered) was 0.91. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Hardness as $CaCO_3$ (Not Filtered). The FOD for hardness as $CaCO_3$ (not filtered) was 96 percent. Hardness as $CaCO_3$ (not filtered) was detected at a mean concentration of 20.8 mg/L, which is similar to that measured in North Fork Koktuli drainage seeps but about 2/3 the mean for Upper Talarik seep samples. The CV for hardness as $CaCO_3$ (not filtered) was 0.67, indicating variability was lower in non-filtered samples. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-25. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1I.

Nutrients were not detected in all samples. Total nitrate+nitrite (as N) was detected in 89 percent of surface water samples, phosphorus was detected in 63 percent of samples, and nitrogen, total ammonia (as N) was detected in only 21 percent of samples. Total orthophosphate [as P] was detected in only one of the water samples from South Fork Koktuli drainage seeps.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.89 (total phosphorus) to 2.17 (total ammonia as N). The CV for all nutrients was 1.41, which is higher than the CV for nutrients in the evaluated rivers, but similar to the CV for seep samples in the Upper Talarik drainage.

Nitrogen, Total Ammonia (as N). The FOD for nitrogen, total ammonia (as N) was 21 percent. Nitrogen, total ammonia (as N) was detected at a mean concentration of 0.056 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total ammonia (as N) was 1.29.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 89 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.26 mg/L, which is within the range of MRLs and MDLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for total nitrate+nitrite (as N) was 2.04, which indicates relatively high variability for this constituent.

Phosphorus. The FOD for phosphorus was 63 percent. Phosphorus was detected at a mean concentration of 0.023, which is within the range of MRLs and MDLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for phosphorus was 1.59.

Total Orthophosphate (as P). Total orthophosphate (as P) was detected in one seep sample from the South Fork Koktuli River drainage (4 percent FOD). Total orthophosphate (as P) was detected at a mean concentration of 0.036 mg/L, which is below MRLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total orthophosphate (as P) was 0.73.

Total Trace Elements

South Fork Koktuli seep data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-25 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1I.

None of the total trace elements were detected in all samples. Total trace elements with the highest FOD were barium and aluminum, at 95 percent and 92 percent, respectively. The FOD of the remaining total trace metals in seep water samples for the South Fork Koktuli drainage ranged from 69 percent (manganese) to 27 percent (cadmium).

Aluminum is present at highest mean concentrations in South Fork Koktuli seep samples (0.50 mg/L). Iron and copper are also at mean concentrations above 0.1 mg/L. Other total trace elements were one to three orders of magnitude lower, and cadmium was detected at the lowest concentration (0.000061 mg/L).

The overall CV for total trace elements of 2.96 is high, indicating substantial variability across seeps in the South Fork Koktuli River drainage is likely reflective of the influence from the mineralized soils in the general deposit area.

Aluminum. The FOD for total aluminum was 92 percent. Aluminum was detected at a mean concentration of 0.5 mg/L, making it the most abundant total trace element in South Fork Koktuli seeps. The CV for total aluminum was 3.55.

Barium. The FOD for total barium was 95 percent. Barium was detected at a mean concentration of 0.0048 mg/L. The CV for total barium was 1.29, which is low relative to other total trace elements in South Fork Koktuli seep samples.

Iron. The FOD for total iron was 62 percent. Iron was detected at a mean concentration of 0.2 mg/L, making it the second most abundant total trace element in South Fork Koktuli seeps. The CV for total iron was 4.13. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Copper. The FOD for total copper was 64 percent. Copper was detected at a mean concentration of 0.12 mg/L, which is the third most abundant of the total trace elements. The CV for total copper was 4.74. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Zinc. The FOD for total zinc was 50 percent. Zinc was detected at a mean concentration of 0.0087 mg/L, which is within the range of MRLs. This indicates the mean concentration is, in part, a function of detection limits and estimated values. The CV for total zinc was 2.11.

Lead. The FOD for total lead was 29 percent. Lead was detected at a mean concentration of 0.00012 mg/L, which is within the range of MRLs. This indicates the mean concentration is, in part, a function of detection limits and estimated values. The CV for total lead was 2.71.

Cadmium. The FOD for total cadmium was 27 percent. Cadmium was detected at a mean concentration of 0.000061 mg/L, which is within the range of MRLs and MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for total cadmium was 1.66.

Arsenic. The FOD for total arsenic was 30 percent. Arsenic was detected at a mean concentration of 0.00093 mg/L, which is within the range of MRLs. This indicates the mean concentration is, in part, a function of detection limits and estimated values. The CV for total arsenic was 1.92.

Nickel. The FOD for total nickel was 49 percent. Nickel was detected at a mean concentration of 0.0016 mg/L. The CV for total nickel was 2.71.

Molybdenum. The FOD for total molybdenum was 48 percent. Molybdenum was detected at a mean concentration of 0.00088 mg/L, which is within the range of MRLs. This indicates the mean concentration is, in part, a function of detection limits and estimated values. The CV for total molybdenum was 2.20.

Manganese. The FOD for total manganese was 69 percent. Manganese was detected at a mean concentration of 0.038 mg/L. The CV for total manganese was 5.52, which is the highest variability of the total trace elements in South Fork Koktuli seeps.

Dissolved Trace Elements

South Fork Koktuli seep data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-25 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1I.

In general, the mean concentrations of dissolved trace elements were slightly lower than total trace elements for South Fork Koktuli seep data. Aluminum and copper had mean concentrations above 0.1 mg/L. The mean concentrations of the remaining dissolved trace elements ranged from 0.000058 (cadmium) to 0.031 (manganese). The FOD of the dissolved trace elements in South Fork Koktuli seep water samples varied from 24 percent (cadmium) to 75 percent (aluminum). The overall CV for dissolved metals in South Fork Koktuli drainage seep samples of 3.09 is more than double the CV for dissolved metals in South Fork Koktuli River water samples, triple the CV for dissolved metals in North Fork Koktuli drainage seep samples, but similar to the Upper Talarik seep sample CV.

Box and whisker plots for each dissolved trace element are provided in Appendix 9.1K. These plots indicate a wide spread of data with multiple outlier values for each dissolved trace element. These data are highly variable because they encompass three drainage areas, multiple seasons, and different geological regimes. Many of the dissolved trace elements with high variability are those associated with the deposit area (e.g., copper, iron).

Aluminum. The FOD for dissolved aluminum was 75 percent. Aluminum was detected at a mean concentration of 0.41 mg/L, which is the most abundant across the dissolved trace elements. The CV for dissolved aluminum was 3.94.

Barium. The FOD for dissolved barium was 99 percent. Barium was detected at a mean concentration of 0.0062 mg/L. The CV for dissolved barium was 1.11.

Iron. The FOD for dissolved iron was 49 percent. Iron was detected at a mean concentration of 0.096 mg/L. The CV for dissolved iron was 6.65, which is the highest variability of the dissolved trace elements in South Fork Koktuli seeps. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Copper. The FOD for dissolved copper was 65 percent. Copper was detected at a mean concentration of 0.13 mg/L. The CV for dissolved copper was 4.47. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Zinc. The FOD for dissolved zinc was 49 percent. Zinc was detected at a mean concentration of 0.0096 mg/L. The CV for dissolved zinc was 1.92.

Lead. The FOD for dissolved lead was 28 percent. Lead was detected at a mean concentration of 0.000077 mg/L, which is within the range of MRLs and MDLs. The mean concentration is primarily a function of detection limits and estimated values. The CV for dissolved lead was 1.66.

Cadmium. The FOD for dissolved cadmium was 24 percent. Cadmium was detected at a mean concentration of 0.000058 mg/L, which is within the range of MDLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved cadmium was 1.65.

Arsenic. The FOD for dissolved arsenic was 25 percent. Arsenic was detected at a mean concentration of 0.0008 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved arsenic was 1.89.

Nickel. The FOD for dissolved nickel was 51 percent. Nickel was detected at a mean concentration of 0.0018 mg/L. The CV for dissolved nickel was 2.47.

Molybdenum. The FOD for dissolved molybdenum was 50 percent. Molybdenum was detected at a mean concentration of 0.00087 mg/L, which is within the range of MRLs. This indicates the mean concentration is, in part, a function of detection limits and estimated values. The CV for total molybdenum was 2.19.

Manganese. The FOD for dissolved manganese was 59 percent. Manganese was detected at a mean concentration of 0.031 mg/L. The CV for dissolved manganese was 6.08. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Cyanides

Total Cyanide. The FOD for total cyanide was 10 percent. Total cyanide was detected at a mean concentration of 0.0033 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for total cyanide was 1.87.

WAD Cyanide. The FOD for WAD cyanide was 11 percent. WAD cyanide was detected at a mean concentration of 0.0025 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for WAD cyanide was 1.31.

Comparison with Water Quality Criteria

South Fork Koktuli seep field and physical parameters, ions, trace elements, and cyanide concentrations were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison for South Fork Koktuli seeps is presented in Table 9.1-26. Concentrations of most constituents met most stringent water quality criteria. Concentrations were outside of the most stringent criteria in at least one sample for the following constituents:

- pH was outside the criteria range in 141 of 202 samples.
- DO was below the most stringent minimum criteria in 24 of 201 samples.
- Alkalinity was below the most stringent minimum criteria in 169 of 206 samples.
- WAD cyanide was above the most stringent maximum criteria in 10 of 206 samples.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates. Seven metals had concentrations above the most stringent maximum criteria in at least one sample:

- Aluminum (total: 49 of 206 samples; dissolved: 27 of 204 samples).

- Cadmium (total: 66 of 202 samples; dissolved: 67 of 206 samples).
- Copper (total: 42 of 206 samples; dissolved: 38 of 182 samples).
- Iron (total: 8 of 206 samples; dissolved: 2 of 203 samples).
- Lead (total: 25 of 206 samples; dissolved: 14 of 182 samples).
- Manganese (dissolved: 89 of 601 samples).
- Nickel (total: 3 of 206 samples; dissolved: 3 of 178 samples).
- Zinc (total: 8 of 206 samples; dissolved: 10 of 179 samples).

With the addition of dissolved manganese, these are the same constituents that also demonstrated naturally occurring concentrations above the most stringent maximum criteria in South Fork Koktuli River samples. The relative frequencies of concentrations above criteria are similar in both stream and seep water samples.

Spatial and Temporal Trend Analysis

Stacked bar graphs were prepared showing median analyte concentrations by seep location for each month for each of the three drainages. These graphs were prepared to identify the relative concentrations of specific constituents in each drainage; however, because not all seeps were sampled at the same time, this information cannot be gleaned from the graphs. The results of the stacked bar graph analysis for the subset of seeps evaluated in each drainage are presented below. Only constituents generally detected above MRLs were included in the following discussion.

Stacked bar graphs for the South Fork Koktuli River drainage seeps are provided in Figures 9.1-169 through 9.1-185. Unlike in the North Fork Koktuli River drainage, only one constituent (molybdenum) had little to no input from seeps in April and May. For other constituents, one pattern was apparent for several trace elements, which were sourced primarily from two locations, SP26 and SP41. This was most apparent for copper (Figure 9.1-181), and to a lesser extent, nickel (Figure 9.1-184). Both SP26 and SP41 are within the general deposit area at lower elevation than the ore deposit, therefore, concentrations of these metals at these sampling locations likely represent groundwater associated with the ore deposit.

Further details are discussed below for constituents generally detected above MRLs at most locations.

Field and Physical Parameters

Total Dissolved Solids. TDS is detected at the most seep locations in the South Fork Koktuli drainage in late summer and early fall, and is well distributed across different seeps (Figure 9.1-169). Except in November, the highest concentrations are routinely at SP26.

Total Suspended Solids. TS**S concentrations are variable in both concentration and location throughout the year. The highest medians are from SP26 in September and SP104 in October, and the lowest occur in June** (Figure 9.1-170).

Major Ins

Sodium. Sodium shows relatively consistent concentrations at most seeps across months. The most seeps have detectable median concentrations in late summer and early fall (Figure 9.1-171).

Potassium. Potassium is dominated by stations SP26 and SP41 in all months for which data were collected except November. Small concentrations from other seep locations are detectable in late summer and early fall (Figure 9.1-172).

Alkalinity. Alkalinity is only above MRLs in August through October and is dominated by station SP96 during this time (Figure 9.1-173).

Sulfate. Sulfate concentrations are dominated by stations SP26 and SP41, and the most seeps have detectable median concentrations in late summer and early fall (Figure 9.1-174).

Chloride. Chloride shows relatively consistent concentrations at most seeps across months. More seeps have detectable median concentrations in late summer and early fall than at other times of the year (Figure 9.1-175).

Fluoride. Fluoride has contributions primarily from stations SP26 and SP41, with neither dominating. Other seeps have detectable median concentrations in August and September (Figure 9.1-176).

Hardness as $CaCO_3$ (Unfiltered). Hardness is generally consistent across months at a given location, but contribution from more seeps occurs in late summer and early fall (Figure 9.1-177).

Nutrients

Total Nitrate+Nitrite (as N). Total nitrate+nitrite (as N) shows contribution from multiple South Fork Koktuli seeps between August and October. Concentrations are dominated by station SP26 early in the year, and at station SP86 in summer and fall (Figure 9.1-178).

Phosphorus. Phosphorus shows the largest median concentration in August at station SP41 (Figure 9.1-179). Concentrations are variable at up to six seeps across months, with June and November having the lowest concentrations.

Trace Elements

Iron. Iron concentrations were dominated by station SP26, with highest concentrations in August and September (Figure 9.1-180). With the exception of station SP41, which exhibited its highest concentration in August, all other seeps had much lower concentrations across all months.

Copper. Copper had reported median concentrations only from stations SP26 and SP41. Concentrations were higher at station SP26 in all months except November; concentrations generally declined at station SP41 between August and November (Figure 9.1-181).

Zinc. Zinc had highest concentrations primarily from stations SP26 and SP41, with neither dominating the total except in November, where no contribution occurred at SP26 (Figure 9.1-182). Other seep locations had much lower concentrations across months.

Cadmium. Cadmium had detectable concentrations from two South Fork Koktuli seeps, station SP26 and SP41, between May and October (Figure 9.1-183). Of these two seeps, only station SP41 had a median concentration of cadmium detected in November, and station SP86 had low concentrations in August, September, and November.

Nickel. Nickel had contributions primarily from stations SP26 and SP41. Station SP26 dominated the median concentrations in all months except November (Figure 9.1-184). Other seeps had low median concentrations, when detected, relative to these two locations.

Molybdenum. Molybdenum had the highest concentrations in August and September. Station SP96 contributes in both months, and station SP41 dominates in August (Figure 9.1-185). Station SP101 was the only seep with detectable median concentrations in June and November, and was also the only seep with detected concentrations in all four of the reported months for this trace element.

9.1.9.3. Results and Discussion: Upper Talarik Seeps

This section presents the findings of the water quality study of seeps sampled in the Upper Talarik Creek drainage. As shown in Table 9.1-27, 338 seep water samples were collected and analyzed between 2004 and 2008 from the Upper Talarik Creek drainage. The number of data points differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, cyanides, and organic compounds.

Field and Physical Parameters

Eight field and physical parameters were measured in Upper Talarik Creek drainage seep samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-27. The overall CV for field and physical parameters in Upper Talarik seep samples was 0.85, which is similar to the North Fork Koktuli seep sample CV and lower than the CV for South Fork Koktuli seep samples.

Total Dissolved Solids. TDS was detected in all samples at a mean concentration of 55.6 mg/L, which is higher than either North Fork Koktuli or South Fork Koktuli seep samples. The CV for TDS was 0.48.

pH (Field). The mean pH was 6.77. The CV for pH was 0.13. A pH median of 6.88 indicates the seep water is slightly acidic, similar to median pH values in rivers. The pH is slightly higher in Upper Talarik seeps than in North Fork Koktuli or South Fork Koktuli seeps.

Dissolved Oxygen. DO was detected in all samples at a mean concentration of 9.51 mg/L. The CV for DO was 0.16.

Water Temperature. The mean water temperature was 3.41^{o}C. The CV for water temperature was 0.40. Water temperature is cold, but slightly warmer than the evaluated rivers and creeks in this study, with a median temperature of 3.14^{o}C.

Specific Conductivity (Field). The mean specific conductivity was 79.2 uS/cm. The CV for specific conductivity was 0.62.

Turbidity. The mean concentration for turbidity was 0.34 NTU. The CV for turbidity was 1.86. Turbidity concentrations are similar across seeps in all three drainages.

Total Suspended Solids. The FOD for TSS was 53 percent. TSS was detected at a mean concentration of 3.02 mg/L. The CV for TSS was 1.97.

Oxidation Reduction Potential. ORP was detected at a mean concentration of 151 mV, ranging from -183 mV to 562 mV. The CV for ORP was 0.74.

Major Ions

Upper Talarik seep data for nine parameters (calcium, magnesium, sodium, and potassium [total and dissolved], as well as alkalinity, sulfate, chloride, fluoride, and hardness [filtered and not filtered]) are discussed in this section and summarized in Table 9.1-27. Data for the other analyzed parameters in this group (e.g., total acidity and ion balance) can be found in Appendix 9.1I.

Calcium, magnesium, and sodium (dissolved and total); chloride; and hardness (filtered and unfiltered) were detected in all samples. Sulfate was detected in 99 percent of samples. Fluoride was detected least often (54 percent FOD).

Dissolved calcium and sulfate were the most abundant individual ions in Upper Talarik seep samples, with mean concentrations of 9.75 and 8.19, respectively. Fluoride was detected at the lowest mean concentration (0.057 mg/L).

Variability is low across major ions except for sulfate, with a CV (2.44) at least 3 times higher than most other major ions. The overall CV for major ions of 0.70 is lower than the CVs in seep samples from the North Fork Koktuli and Upper Talarik drainages, but higher than the CV for major ions from the Upper Talarik Creek water samples.

Piper plots summarizing the major ionic distribution in the Upper Talarik drainage are provided in Appendix 9.1J. Box and whisker plots for each major ion are provided in Appendix 9.1K. These plots indicate higher variability than major ions in the three main rivers or Kaskanak Creek.

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 9.68 mg/L and is the most abundant major ion in Upper Talarik seeps. The CV for total calcium was 0.45.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 9.75 mg/L. The CV for dissolved calcium was 0.44.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 1.94 mg/L. The CV for total magnesium was 0.88.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 1.97 mg/L. The CV for dissolved magnesium was 0.87.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.64 mg/L, making it the third most abundant ion in Upper Talarik seep samples. The CV for total sodium was 0.34.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.68 mg/L. The CV for dissolved sodium was 0.33.

Potassium (Total). The FOD for total potassium was 79 percent. Potassium was detected at a mean concentration of 0.55 mg/L. The CV for total potassium was 0.82.

Potassium (Dissolved). The FOD for dissolved potassium was 81 percent. Potassium was detected at a mean concentration of 0.49 mg/L. The CV for dissolved potassium was 0.89.

Alkalinity, Total. The FOD for total alkalinity was 94 percent. Total alkalinity was detected at a mean concentration of 30.3 mg/L. The CV for total alkalinity was 0.62.

Sulfate. The FOD for sulfate was 99 percent. Sulfate was detected at a mean concentration of 8.19 mg/L, which is second highest among major ions in Upper Talarik seeps. The CV for sulfate was 2.44.

Chloride. Chloride was detected in all samples at a mean concentration of 0.87 mg/L. The CV for chloride was 0.22.

Fluoride. The FOD for fluoride was 54 percent. Fluoride was detected at a mean concentration of 0.057 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for fluoride was 0.59.

Hardness as $CaCO_3$ (Filtered). Hardness as $CaCO_3$ (filtered) was detected in all samples at a mean concentration of 30.5 mg/L. The CV for hardness as $CaCO_3$ (filtered) was 0.33.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected in all samples at a mean concentration of 32.2 mg/L. The CV for hardness as $CaCO_3$ (not filtered) was 0.51. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria, but is harder than seeps in the North Fork Koktuli River and South Fork Koktuli River drainages.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-27. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1I.

Nutrients were not detected in all samples. Total nitrate+nitrite (as N) was detected in 88 percent of surface water samples, phosphorus was detected in 77 percent of samples, and nitrogen, total ammonia (as N) was detected in only 23 percent of samples. Total orthophosphate [as P] was not detected in any of the samples from Upper Talarik drainage seeps.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.97 (total phosphorus) to 1.57 (total ammonia as N). The CV for all nutrients was 1.31, which is higher than the CV for nutrients in the evaluated rivers, but similar to the CV for seep samples in the South Fork Koktuli drainage.

Nitrogen, Total Ammonia (as N). The FOD for nitrogen, total ammonia (as N) was 17 percent. Nitrogen, total ammonia (as N) was detected at a mean concentration of 0.042 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for total ammonia (as N) was 1.39.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 98 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.42 mg/L, which is higher than seeps in either the North Fork Koktuli River or South Fork Koktuli River drainages. The CV for total nitrate+nitrite (as N) was 1.47.

Phosphorus. The FOD for phosphorus was 65 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.018 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for phosphorus was 1.29.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any seep sample from the Upper Talarik Creek drainage.

Total Trace Elements

Upper Talarik seep data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-27 and discussed below. Other total trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other total trace elements are presented in Appendix 9.1I.

Total trace elements were not detected in all samples. The highest FOD for total trace elements was for barium and aluminum at 99 percent and 84 percent, respectively. The FOD for the remaining total trace metals in Upper Talarik seep water samples varied from 67 percent (manganese) to 16 percent (cadmium).

Aluminum and iron were present at the highest mean concentrations (0.19 and 0.11 mg/L, respectively). Cadmium was detected at the lowest mean concentration (0.000031 mg/L).

The overall CV for total trace elements of 3.90 is high, indicating substantial variability across seeps in the Upper Talarik Creek drainage, most likely reflective of the influence from the mineralized soils in the general deposit area.

Aluminum. The FOD for total aluminum was 84 percent. Aluminum was detected at a mean concentration of 0.19 mg/L, which is the most abundant total trace element in Upper Talarik seep samples. The CV for total aluminum was 4.39. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Barium. The FOD for total barium was 99 percent. Barium was detected at a mean concentration of 0.0049 mg/L. The CV for total barium was 1.10.

Iron. The FOD for total iron was 64 percent. Iron was detected at a mean concentration of 0.11 mg/L, which is the second most abundant total trace element in Upper Talarik seeps. The CV for total iron was 4.43. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Copper. The FOD for total copper was 59 percent. Copper was detected at a mean concentration of 0.007 mg/L. The CV for total copper was 12.1, which is the highest variability in seeps across all metals

and drainages. The very high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Zinc. The FOD for total zinc was 49 percent. Zinc was detected at a mean concentration of 0.0026 mg/L. The CV for total zinc was 1.79.

Lead. The FOD for total lead was 30 percent. Lead was detected at a mean concentration of 0.00014 mg/L. The CV for total lead was 4.33. The high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Cadmium. The FOD for total cadmium was 16 percent. Cadmium was detected at a mean concentration of 0.000031 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for total cadmium was 1.02.

Arsenic. The FOD for total arsenic was 61 percent. Arsenic was detected at a mean concentration of 0.0017 mg/L. The CV for total arsenic was 1.39.

Nickel. The FOD for total nickel was 65 percent. Nickel was detected at a mean concentration of 0.0013 mg/L. The CV for total nickel was 6.64. The high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Molybdenum. The FOD for total molybdenum was 58 percent. Molybdenum was detected at a mean concentration of 0.00043 mg/L, which is within the range of MRLs and MDLs. The mean concentration is a function of detection limits and estimated values. The CV for total molybdenum was 1.20.

Manganese. The FOD for total manganese was 67 percent. Manganese was detected at a mean concentration of 0.006 mg/L, which is the third most abundant total trace element in Upper Talarik seeps. The CV for total manganese was 4.45. The high variability reflects the influence of the general deposit area on some of the seep locations in this drainage.

Dissolved Trace Elements

Upper Talarik seep data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-27 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1I.

Dissolved trace elements were not detected in all samples. Barium was detected in all but one of 284 samples (99.6 percent FOD). The FOD of the remaining dissolved trace elements in Upper Talarik seep water samples varied from 17 percent (cadmium) to 70 percent (aluminum).

Aluminum was detected at the highest mean concentration of dissolved trace elements (0.16 mg/L). All other dissolved trace elements, except iron, had mean concentrations greater than one order of magnitude lower. The lowest mean concentration was for cadmium (0.000030 mg/L).

The overall CV for dissolved trace elements of 3.27 is high, indicating substantial variability across seeps in the Upper Talarik Creek drainage, most likely reflective of the influence from the mineralized soils in the general deposit area.

Box and whisker plots for each dissolved trace metal are provided in Appendix 9.1K. These plots indicate a wide spread of data with multiple outlier values for each dissolved trace element. These data are highly variable because they encompass three drainage areas, multiple seasons, and different geological regimes. Many of the dissolved trace elements with high variability are those associated with the deposit area (e.g., copper, iron).

Aluminum. The FOD for dissolved aluminum was 70 percent. Aluminum was detected at a mean concentration of 0.16 mg/L, which is the most abundant dissolved trace element in the Upper Talarik seep samples. The CV for dissolved aluminum was 5.15. The high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Barium. The FOD for dissolved barium was 99.6 percent. Barium was detected at a mean concentration of 0.0054 mg/L. The CV for dissolved barium was 1.07.

Iron. The FOD for dissolved iron was 49 percent. Iron was detected at a mean concentration of 0.063 mg/L, representing the second most abundant dissolved trace element in Upper Talarik seep samples. The CV for dissolved iron was 4.92. The high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Copper. The FOD for dissolved copper was 62 percent. Copper was detected at a mean concentration of 0.008 mg/L. The CV for dissolved copper was 10.8. The very high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Zinc. The FOD for dissolved zinc was 51 percent. Zinc was detected at a mean concentration of 0.0025 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved zinc was 1.78.

Lead. The FOD for dissolved lead was 33 percent. Lead was detected at a mean concentration of 0.000077 mg/L. The CV for dissolved lead was 1.14.

Cadmium. The FOD for dissolved cadmium was 17 percent. Cadmium was detected at a mean concentration of 0.000031 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for dissolved cadmium was 0.93.

Arsenic. The FOD for dissolved arsenic was 55 percent. Arsenic was detected at a mean concentration of 0.0016 mg/L. The CV for dissolved arsenic was 1.43.

Nickel. The FOD for dissolved nickel was 55 percent. Nickel was detected at a mean concentration of 0.001 mg/L, which is within the range of MRLs. The mean concentration is, in part, a function of detection limits and estimated values. The CV for dissolved nickel was 2.55.

Molybdenum. The FOD for dissolved molybdenum was 63 percent. Molybdenum was detected at a mean concentration of 0.00040 mg/L, which is within the range of MRLs and MDLs. The mean concentration is a function of detection limits and estimated values. The CV for dissolved molybdenum was 1.21.

Manganese. The FOD for dissolved manganese was 56 percent. Manganese was detected at a mean concentration of 0.0060 mg/L. The CV for dissolved manganese was 4.96. The high variability reflects the influence of the general deposit area on some of the seep locations in the Upper Talarik Creek drainage.

Cyanides

Total Cyanide. The FOD for total cyanide was 12 percent. Total cyanide was detected at a mean concentration of 0.0025 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for total cyanide was 1.69.

WAD Cyanide. The FOD for WAD cyanide was 13 percent. WAD cyanide was detected at a mean concentration of 0.0027 mg/L, which is below MRLs and in the range of MDLs. The mean concentration is a function of detection limits and estimated values. The CV for WAD cyanide was 1.78.

Comparison with Water Quality Criteria

Upper Talarik seep field and physical parameters, ions, trace elements, and cyanide concentrations were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison is presented in Table 9.1-28. Concentrations of most constituents met the most stringent quality criteria. Concentrations were outside the most stringent criteria in at least one sample for the following constituents:

- pH was outside the criteria range in 121 out of 335 samples.
- Alkalinity was below the most stringent minimum criteria in 86 out of 338 samples.
- DO was below the most stringent minimum criteria in 24 out of 323 samples.
- WAD cyanide was above the most stringent maximum criteria in 25 out 338 of samples.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates. Concentrations were above the most stringent maximum criteria in at least one sample for the following trace elements:

- Aluminum (total: 43 of 338 samples).
- Iron (total: 10 of 338 samples).
- Copper (total: 18 of 338 samples; dissolved: 14 of 273 samples).
- Lead (total: 13 of 338 samples; dissolved: 4 of 282 samples).
- Cadmium (total: 10 of 338 samples; dissolved: 8 of 336 samples).
- Zinc (total: 2 of 338 samples; dissolved: 1 of 262 samples).

- Nickel (total: 3 of 333 samples; dissolved: 2 of 240 samples).

With some exceptions, these are the same constituents that also demonstrated naturally occurring concentrations above most stringent maximum criteria in Upper Talarik Creek samples. The relative frequencies of concentrations above the most stringent maximum criteria are a bit higher in seep samples than in stream water samples, particularly for the non-trace elements. The exceptions are that arsenic and manganese concentrations were not above the most stringent maximum criteria in any Upper Talarik seep samples, and nickel and zinc were not above the most stringent maximum criteria in any Upper Talarik Creek water samples.

Spatial and Temporal Trend Analysis

Stacked bar graphs were prepared showing median analyte concentrations by seep location for each month for each of the three drainages. These graphs were prepared to identify the relative concentrations of specific constituents in each drainage; however, because not all seeps were sampled at the same time, this information cannot be gleaned from the graphs. The results of the stacked bar graph analysis for the subset of seeps evaluated in each drainage are presented below. Only constituents generally detected above MRLs were included in the following discussion.

Stacked bar graphs for the Upper Talarik Creek drainage seeps are provided in Figures 9.1-186 through 9.1-202. General trends were less apparent for seep data in this drainage. Concentrations of constituents were generally low in March and were only detected in station SP40. Further details are discussed below for constituents generally detected above MRLs at most locations.

Field and Physical Parameters

Total Dissolved Solids. The **majority of Upper Talarik seeps had detectable median concentrations of** TDS in summer and fall, but only a few seeps had contributions in March and May (Figure 9.1-186). Concentrations are generally consistent across months for a given seep. Station SP66 generally had the highest median concentrations across months except in March, when only station SP40 had detected levels of TDS.

Total Suspended Solids. TSS concentrations are above MRLs for the most Upper Talarik seeps in summer, and the highest median concentration is in August at station SP73 (Figure 9.1-187).

Major Ions

Sodium. Sodium shows relatively consistent concentrations at most seeps across months. Relative to winter and spring, more seeps have detectable medians in summer and fall (Figure 9.1-188).

Potassium. Potassium shows relatively consistent concentrations at most seeps across months. Relative to winter and spring, more seeps have detectable medians in summer and fall (Figure 9.1-189). Higher median concentrations are apparent at several locations in October relative to other months.

Alkalinity. Alkalinity is consistent in concentrations and sources between June and November; few seeps contribute in winter and spring months. The highest median concentration in most months is station SP66 (Figure 9.1-190).

Sulfate. Sulfate concentrations are dominated by station SP62 in most months (Figure 9.1-191). Other locations are generally consistent in concentration across months.

Chloride. Chloride shows relatively consistent concentrations at most seeps across months. Fewer seeps have detectable median concentrations in winter and spring months (Figure 9.1-192).

Fluoride. Fluoride shows variable concentrations at most Upper Talarik seeps across months. Many of the medians are near the MRLs, but the highest median concentrations occurred in August at station SP73 and in October at station SP62 (Figure 9.1-193).

Hardness as $CaCO_3$ (Unfiltered). Hardness as $CaCO_3$ (unfiltered) is generally consistent across months at a given location, but more Upper Talarik seeps have detectable median concentrations in late summer and fall (Figure 9.1-194). The highest concentrations are consistently at station SP66 except in March, when only a single seep (station SP40) has a measurable median.

Nutrients

Total Nitrate+Nitrite (as N). Total nitrate+nitrite (as N) shows detectable median concentrations from multiple seeps between June and November, with consistent concentrations across months for any given seep (Figure 9.1-195).

Phosphorus. Phosphorus concentrations were variable, but additional seeps had detectable median concentrations later in the year relative to earlier months of the year (Figure 9.1-196). Concentrations were only reported at a single seep in March at a median concentration below the MRL.

Trace Elements

Iron. Iron concentrations were mostly consistent across months, with two exceptions. Station SP73, which is located due east of the general deposit area, had the highest mean concentration of any month and location in August, yet was much lower in September. Station SP75 had a much higher median concentration in September than in other months (Figure 9.1-197).

Copper. Copper median concentrations were sporadic and generally at low concentration. The highest median concentration was at station SP116 in August, which is located in the general deposit area (Figure 9.1-198). August also had the highest median concentration at station SP78, while September exhibited the highest median concentrations at stations SP66 and SP73.

Zinc. Zinc median concentrations were generally highest at SP62 across months. Concentrations were variable and detected concentrations were sporadic at other seeps (Figure 9.1-199).

Arsenic. For arsenic, the highest median concentrations consistently occurred at seeps SP84 and SP78, which are located well south and east of the ore body, respectively (Figure 9.1-200). The other consistently detected median seep station for arsenic, SP109, is also located in this general area. Concentrations are quite consistent over the sampling year, but each sampling month only had four to six seeps with detected median concentrations.

Nickel. Nickel concentrations were variable, but more locations contributed in summer and November than in other months. Station SP62 had the highest median concentrations in most months (Figure 9.1-201). Stations SP109 and SP66 had their highest median concentration in November as well.

Molybdenum. Median concentrations of molybdenum are highest from May through November at station SP73, with the exception of October when no contribution occurs (Figure 9.1-202). Seep station SP73 is located due east of the general deposit area.

9.1.9.4. Regional Evaluation of Seeps Data

The following subsections compare and contrast seeps data across different drainages. Additionally, spatial and temporal trend analyses were conducted for seeps in each watershed. The seeps evaluated from each drainage area were selected based on their unique characteristics and impact on overall surface water quality (e.g., high-flow seeps were preferentially selected over low-flow seeps), as discussed in Section 9.1.5. The seeps and their rationale for inclusion, based on the criteria developed by Water Management Consultants, are presented in Table 9.1-4. The evaluated parameters are the same as those evaluated for rivers.

Comparison of Constituents Across Seeps from Different River Drainages

Evaluation of descriptive statistics indicates five ions were consistently most abundant and had the highest mean concentrations in the seep water collected in all three drainages. These include total and dissolved sodium, magnesium, potassium, calcium, and sulfate. Total and dissolved magnesium and calcium were detected at the highest mean concentrations in Upper Talarik seep samples, whereas sodium and potassium were at similar concentrations across all three drainages. Sulfate was highest in South Fork Koktuli seep samples, which had a mean 5 times higher than concentrations in North Fork Koktuli seeps. Sulfate concentrations were intermediate in Upper Talarik seep samples.

In general, mean concentrations of trace metals were lowest for seeps in the North Fork Koktuli River drainage. The highest concentrations for seeps were divided between the South Fork Koktuli River and Upper Talarik Creek drainages, likely due to their partial proximity to the general deposit area. Trace elements of particular note are the wide range of aluminum and copper concentrations. Total aluminum concentrations from North Fork Koktuli seep samples had a mean of 0.025 mg/L, while total aluminum from South Fork Koktuli seep samples had a mean of 0.50 mg/L. Total copper concentrations from North Fork Koktuli seep samples had a mean of 0.00037 mg/L, and total copper concentrations from South Fork Koktuli seep samples had a mean of 0.12 mg/L.

The Upper Talarik Creek drainage, northeast of the general deposit area, presented the highest mean detected concentrations of the following constituents:

- Total and dissolved calcium in seep sample location SP66.
- Total and dissolved magnesium in seep sample location SP66.
- Total and dissolved potassium in seep sample location SRK01.
- Total sodium in seep sample location SRK01.
- Dissolved sodium in seep sample location SP65.

The South Fork Koktuli seeps located in the general deposit area presented the highest concentrations of the following constituents:

- Aluminum in seep sample location SRK08.
- Copper in seep sample location SRK08.

- Zinc in seep sample location SRK08.
- Iron in seep sample location SRK04, located near SP26.

As presented in the above summary of seep data, major ion and trace element concentrations showed considerable variability within and across seeps in the three drainages. The remainder of this section presents a discussion of patterns observed across different drainages and addresses Mann-Whitney U-Tests conducted to identify statistical differences in trace element seep water concentrations across individual drainages. The Mann-Whitney U-Test is further described in Section 9.1.8, and results of Mann-Whitney U-Tests for pair-wise comparison of constituents in seeps among the three drainages (using a p-value of 0.05) are presented in Table 9.1-29.

The range of concentrations of the constituents in seeps is primarily due to the effect of drainage subsurface water conditions. These drainages differ in geological formation, elevations in relation to the deposit area, presence of binding substances such as ions (i.e., sulfates, chloride ions), suspended and dissolved solids, ORP, water hardness, pH, and groundwater-to-surface water discharge rates. The following provides a discussion of the results of statistical comparison among these drainages.

For field and physical parameters in seep water samples, statistical differences across at least two of the three drainages were identified for TDS and pH. TDS was significantly different across all three pairs, while pH was significantly different between South Fork Koktuli seeps and those of the North Fork Koktuli drainage area and Upper Talarik Creek drainage area. TSS was significantly different between North Fork Koktuli and South Fork Koktuli seep samples.

For major ions, significant differences between at least two of the drainage pairs were identified for sodium, potassium, alkalinity, sulfate, fluoride, and hardness. Alkalinity, sulfate, and hardness as $CaCO_3$ (not filtered) were different in all three drainage pairs. Sodium was significantly different in Upper Talarik seeps than in seeps in the other two drainages, fluoride was different in South Fork Koktuli seeps than in the North Fork Koktuli and Upper Talarik seeps, and potassium was different in North Fork Koktuli seeps than the other two drainages.

For nutrients, statistical differences in total nitrate+nitrite (as N) concentrations were identified between the Upper Talarik seeps and those from the North Fork Koktuli and South Fork Koktuli seeps.

For trace elements, significant differences were apparent for four constituents in each drainage pair. Significantly statistical differences across all three pair-wise drainage comparisons were observed for arsenic, cadmium, copper, iron, nickel, and zinc. Nickel concentrations were significantly different across all three pairs. Arsenic was significantly different in Upper Talarik seeps relative to seeps in the other two drainages, while copper and zinc were significantly different in South Fork Koktuli seeps relative to seeps in the other two drainages. Iron was significantly different between North Fork Koktuli and Upper Talarik seeps.

It appears that peak concentrations in the seeps are related either to: (1) spring snowmelt, or (2) shallow groundwater in the late summer/early fall. This time of year is when aquifers are recharged from precipitation during the summer; water levels drop during the winter.

Impact of Discharge Velocity on Constituent Concentrations within Drainages

The pair-wise non parametric Mann-Whitney U-Test was performed to determine whether seep discharge velocity affects the concentration of field and physical properties, major ions, trace elements, or cyanides in the seeps within each individual drainage.

Seep locations in each watershed were grouped by seep velocity. Four seep discharge velocity categories were assigned to the North Fork Koktuli River and Upper Talarik Creek drainage area based on baseline flow during dry conditions:

- High velocity: greater than 0.5 cubic feet per second
- Medium velocity: less than 0.5 but more than 0.1 cubic feet per second
- Low velocity: less than 0.1 but more than 0.01 cubic feet per second
- Very low velocity: less than 0.01 cubic feet per second.

No high-velocity seeps were identified in the South Fork Koktuli River drainage, so only three categories were assigned to seeps from this drainage. Table 9.1-30 presents results of the statistical tests evaluating seep discharge on concentrations of trace elements in North Fork Koktuli, South Fork Koktuli, and Upper Talarik seeps. There are 10 high-velocity seeps, 37 medium-velocity seeps, 58 low-velocity seeps, and 22 very-low-velocity seeps. The subset selected for further study (Table 9.1-4) represents approximately 20 percent of the baseline seeps.

The results of the Mann-Whitney U-Tests (Table 9.1-30) indicate chloride, arsenic, and WAD cyanide do not statistically differ in concentrations between discharge levels. Therefore, it is expected that all other constituents will be influenced by seep discharge. Fewer constituents are affected by seep discharge in the North Fork Koktuli seeps than in seeps from the other drainages. Part of this difference may be in the substantially fewer number of sampling locations in the North Fork Koktuli River drainage area relative to the other drainages. Therefore, there are fewer locations for a correlation or trend to be identified statistically.

In general, for all three drainages, the largest difference in trace metal concentrations was between extremes of seep velocity (i.e., high and lowest velocity seeps and medium and lowest velocity seeps). Because there were no high-velocity seeps in the South Fork Koktuli River drainage area, most of the statistically significant differences were between medium- and low-velocity seeps, and low- and lowest-velocity seeps.

This information indicates concentrations of constituents discharged through seeps are at least, in part, dependent on the water velocity of the seep. This is further addressed below.

Effect of Flow Rate on Seep Concentrations

The relationship between discharge velocities and constituent concentrations was further evaluated by plotting the subset of seep sampling locations versus both median constituent concentrations and discharge velocities (y-axis). This analysis was performed separately for each drainage to identify if discharge velocity had an effect on constituent concentrations at a particular seep location.

North Fork Koktuli River Drainage

The drainage-specific results for constituents typically detected above MRLs are presented graphically in Figures 9.1-203 through 9.1-216. Although a few constituents showed direct or inverse relationships with seep flow, the majority had concentrations that appear independent of seep flow. Of the constituents that demonstrated a trend, more exhibit an inverse relationship with flow than a direct one.

Constituents showing an inverse relationship with seep flow include TSS (Figure 9.1-204), sulfate (Figure 9.1-208), and iron (Figure 9.1-212). For iron, the two seeps with median concentrations above the MRL (SP44 and SP99) are both low-flow seeps.

The only constituent showing a direct relationship with seep flow in the North Fork Koktuli River drainage is alkalinity (Figure 9.1-207).

Based on evaluation of the figures, the other constituents appear to be independent of seep flow, but some constituents are more clearly independent than others. For example, sodium concentrations appear to be slightly proportional to flow, but no clear trend is apparent (Figure 9.1-205). For potassium (Figure 9.1-206), the highest median is associated with a high-flow seep (station SP57), but no relationship is apparent. Also, hardness shows some relationship to flow, because low concentrations are present at low-flow seep station SP99, and high concentrations are present at high-flow seep station SP57 (Figure 9.1-210). However, this pattern is not consistent across seeps.

South Fork Koktuli River Drainage

Flow velocity and trace element concentration graphs for the South Fork Koktuli seeps are provided in Figures 9.1-217 through 9.1-230. Although a few constituents showed inverse relationships with seep flow, the majority had concentrations that appear independent of seep flow.

The constituents showing an inverse relationship with seep flow include TDS (Figure 9.1-217), sulfate (Figure 9.1-222), potassium (Figure 9.1-220), copper (Figure 9.1-227), and nickel (Figure 9.1-229).

Based on evaluation of the figures, the other constituents appear to be independent of seep flow, but some constituents are more clearly independent than others. For example, the highest potassium median is associated with a low-flow seep (station SP26), but insufficient data are available to identify an inverse trend (Figure 9.1-220). Copper median concentrations may appear related to seep flow given the small sample size (Figure 9.1-227), but no trends can be identified.

For alkalinity (Figure 9.1-221) and molybdenum (Figure 9.1-230), only moderate-flow seeps are included in the evaluation, so no trends could be evaluated.

Upper Talarik Creek Drainage

Flow velocity and trace element concentration graphs for the Upper Talarik seeps are provided in Figures 9.1-231 through 9.1-247. All but four constituents had concentrations that appear independent of seep flow. Unlike the North Fork Koktuli River and South Fork Koktuli River, all four of these constituents exhibited a direct relationship with seep flow (i.e., higher median concentrations in higher-flow seeps).

Constituents showing this direct relationship with seep flow include TSS (Figure 9.1-232), iron (Figure 9.1-241), lead (Figure 9.1-244), and molybdenum (Figure 9.1-247). Note that TSS showed the opposite

relationship with seep flow in the North Fork Koktuli River and South Fork Koktuli River drainages, as did iron in the North Fork Koktuli seeps.

9.1.10. Lakes and Ponds

This section presents the findings of the water quality study of lakes located in the mine study area. Water samples and measurement of physical parameters were obtained from a variety of lakes to assess spatial and temporal variability of trace elements and ions in the study area. The analysis was conducted using data acquired during 2006 and 2007.

Primary lakes in the study area include:

- Black Lake, located in the northwest portion of the study area.
- Lilly Lake, located north of Big Wiggly Lake.
- Big Wiggly Lake, located north of the deposit area at the origin of the North Fork Koktuli River.
- Frying Pan Lake, located just south of the deposit area.
- Chiquita Lake, located south of Sharp Mountain.
- Lake 2, located at the southern boundary of the study area near stream sampling location UT100A.

9.1.10.1. Results and Discussion: All Lakes and Ponds Data

This section presents the findings of the water quality study of lakes in the mine study area. Surface water samples and measurement of field and physical parameters, major ions, nutrients, trace elements, and cyanides in the study area were acquired between 2006 and 2007 at the locations shown on Figure 9.1-5.

The lakes study area encompasses approximately 392 square miles and is drained by the North Fork Koktuli River, South Fork Koktuli River, and Upper Talarik Creek (Figure 9.1-6). All sampling locations were more than 1 mile from the general deposit area.

As shown in Table 9.1-31, 47 surface water samples were collected from 19 lakes in the study area. The number of data points differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction. A summary of data collected across lakes and ponds and included in this study is provided in Appendix 9.1L.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, and cyanides, and compare results from lakes with those for rivers, creeks, and seeps where notable.

Field and Physical Parameters

Eight field and physical parameters were measured in the lakes study area surface water samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-31. The overall CV for field and physical parameters was 0.83, which is similar to the overall CVs in both seep and river samples for this group of parameters.

Total Dissolved Solids. The FOD for TDS was 98 percent, with a mean concentration of 41.8 mg/L. The CV for TDS was 0.5.

pH (Field). The median field pH was 7.17 (pH units), indicating that the lake water is slightly basic. This is different from the neutral to slightly acidic-trending pH in the study area rivers. The CV for pH was 0.12.

Dissolved Oxygen. DO was detected in all samples at a mean concentration of 8.51 mg/L, which is slightly lower than that seen in the study area rivers. The CV for DO was 0.24.

Water Temperature. The mean water temperature was 12^{o}C. The CV for water temperature was 0.32. Water temperature is much warmer in study area lakes than in the study area rivers or creeks, with a median temperature of 11.6^{o}C, because lakes represent primarily standing water that warms in the summer.

Specific Conductivity (Field). The mean concentration for specific conductivity, identified in all samples, was 61.6 uS/cm. The CV for specific conductivity was 1.69, indicating relatively high variability for this constituent.

Turbidity. The mean concentration for turbidity was 1.64 NTU. The CV for turbidity was 1.02. Turbidity is generally low in the lakes study area, as indicated by the median concentration of 1.08 NTU.

Total Suspended Solids. The FOD for TSS was 98 percent. TSS was detected at a mean concentration of 3.06 mg/L. The CV for TSS was 1.42, indicating relatively high variability for this constituent.

Oxidation Reduction Potential. ORP was detected in all samples at a mean concentration of 67.2 mV, with a range from -78 mV to 223 mV. The CV for ORP was 1.64.

Major Ions

The Lakes study area data for nine constituents (calcium, magnesium, sodium, and potassium [dissolved and total], as well as alkalinity, sulfate, chloride, fluoride, and hardness [not filtered]) are discussed in this section and summarized in Table 9.1-31. Data for the other analyzed parameters (total acidity and ion balance) can be found in Appendix 9.1L.

All of the major ions except total potassium (98 percent FOD), alkalinity (89 percent FOD), sulfate (98 percent FOD), and fluoride (51 percent FOD) were detected in all samples. Of the individual ions in this group of parameters, calcium and sulfate were detected at the highest mean concentrations; fluoride had a mean concentration one to two orders of magnitude lower than the other individual ions (Table 9.1-31).

The overall CV for the major ions was 0.73, indicating relatively low variability in concentrations of these parameters relative to trace elements. Box and whisker plots for each major ion are provided in Appendix 9.1K. Piper plots summarizing the major ionic distribution in the lakes are provided in Appendix 9.1M.

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 5.75 mg/L, which is the most abundant across the major ions. The CV for total calcium was 0.65.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 5.78 mg/L. The CV for dissolved calcium was 0.62.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 1.26 mg/L. The CV for total magnesium was 0.75.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 1.29 mg/L. The CV for dissolved magnesium was 0.7.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.53 mg/L. The CV for total sodium was 0.83.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.52 mg/L. The CV for dissolved sodium was 0.78.

Potassium (Total). The FOD for total potassium was 98 percent. Potassium was detected at a mean concentration of 0.3 mg/L. The CV for total potassium was 0.61.

Potassium (Dissolved). Dissolved potassium was detected in all samples at a mean concentration of 0.3 mg/L. The CV for dissolved potassium was 0.58.

Alkalinity, Total. The FOD for total alkalinity was 89 percent. Total alkalinity was detected at a mean concentration of 18.5 mg/L. The CV for total alkalinity was 0.61.

Sulfate. The FOD for sulfate was 98 percent. Sulfate was detected at a mean concentration of 5.13 mg/L, making it the second most abundant major ion in lake waters. The CV for sulfate was 1.81, reflecting relatively high variability in concentrations.

Chloride. Chloride was detected in all samples at a mean concentration of 0.52 mg/L. The CV for chloride was 0.36, which is low relative to other major ions.

Fluoride. The FOD for fluoride was 51 percent. Fluoride was detected at a mean concentration of 0.032 mg/L, which is below MRLs. This indicates the mean concentration is largely a function of detection limits and estimated values. The CV for fluoride was 0.59.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected in all samples at a mean concentration of 19.5 mg/L. The CV for hardness as $CaCO_3$ (not filtered) was 0.66. Hardness values indicate the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-31. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1L.

Nutrients were not detected in all samples. Total phosphorus was detected in 98 percent of pond samples, nitrate+nitrite as N was detected in 60 percent of samples, and nitrogen, total ammonia (as N) was

detected in only36 percent of samples. Total orthophosphate [as P] was not detected in any of the pond water samples.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.63 (total phosphorus) to 1.81 (nitrate+nitrite as N). The CV for all nutrients was 1.14, which is higher than the CV for nutrients in the evaluated rivers, but lower than the CV for nutrients in seeps.

Nitrogen, Total Ammonia (as N). The FOD for total ammonia (as N) was 36 percent. Nitrogen, total ammonia (as N) was detected at a mean concentration of 0.039 mg/L, which is below MRLs. This indicates the mean is primarily a function of detection limits and estimated values. The CV for total ammonia (as N) was 0.98.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 60 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.11 mg/L. The CV for total nitrate+nitrite (as N) was 1.81, which indicates relatively high variability in this constituent.

Phosphorus. The FOD for phosphorus was 98 percent, which is much higher than in rivers or seeps within the study area. Phosphorus was detected at a mean concentration of 0.022 mg/L, which is above MRLs and MDLs. The CV for phosphorus was 0.63.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any lake samples.

Total Trace Elements

The lakes data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-31 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1L.

Total aluminum, barium, copper, and manganese were detected in all lakes study area samples. Iron and zinc were present in more than 95 percent of samples. Total cadmium was the only constituent not detected in any lake samples. Total iron was detected at the highest concentrations, with a mean concentration of 0.35 mg/L. Other trace elements were detected at one to three orders of magnitude lower. Lead was detected at the lowest mean concentration (0.00018 mg/L).

The overall CV for total trace elements in lake surface water samples was 1.22, which is higher than the major ions for these same lakes.

Aluminum. Total aluminum was detected in all samples at a mean concentration of 0.062 mg/L, which is the second highest mean of all total trace elements for lake samples. The CV for total aluminum was 1.26.

Barium. Total barium was detected in all samples at a mean concentration of 0.0042 mg/L. The CV for total barium was 0.75.

Iron. The FOD for total iron was 96 percent. Iron was detected at a mean concentration of 0.35 mg/L. Iron was the most abundant trace element for lake samples in the study area. The CV for total iron was 1.35.

Copper. Total copper was detected in all samples at a mean concentration of 0.0008 mg/L. The CV for total copper was 1.16.

Zinc. The FOD for total zinc was 98 percent. Zinc was detected at a mean concentration of 0.0029 mg/L. The CV for total zinc was 0.87.

Lead. The FOD for total lead was 62 percent. Lead was detected at a mean concentration of 0.00018 mg/L. The CV for total lead was 1.21.

Cadmium. Cadmium was not detected in any sample.

Arsenic. The FOD for total arsenic was 49 percent. Arsenic was detected at a mean concentration of 0.00077 mg/L. The CV for total arsenic was 1.86, which represents the highest variability in lakes among the total trace elements.

Nickel. The FOD for total nickel was 77 percent. Nickel was detected at a mean concentration of 0.0003 mg/L. The CV for total nickel was 0.88.

Molybdenum. The FOD for total molybdenum was 89 percent. Molybdenum was detected at a mean concentration of 0.00038 mg/L. The CV for total molybdenum was 1.17.

Manganese. Total manganese was detected in all samples at a mean concentration of 0.03 mg/L, which is the third highest mean of the trace elements for lakes in the study area. The CV for total manganese was 1.73.

Dissolved Trace Elements

Lake surface water data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-31 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1L.

Dissolved aluminum, barium, copper, zinc, and manganese were detected in all lake samples. Dissolved cadmium was the only constituent not detected in any lake samples. Dissolved iron was detected at the highest concentrations, with a mean of 0.17 mg/L. Mean concentrations of all other trace elements were one to two orders of magnitude lower, ranging from 0.020 mg/L for dissolved aluminum to 0.00011 mg/L for dissolved lead.

The overall CV for dissolved trace elements in lake surface water samples (1.25) was similar to that for total trace elements for the same samples (1.22).

Aluminum. Dissolved aluminum was detected in all samples at a mean concentration of 0.02 mg/L, about one-third the mean concentration for total aluminum. The CV for dissolved aluminum was 1.42.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0036 mg/L. The CV for dissolved barium was 0.74.

Iron. The FOD for dissolved iron was 89 percent. Iron was detected at a mean concentration of 0.17 mg/L. Dissolved iron was the most abundant of the dissolved trace elements in lake surface water samples. The CV for dissolved iron was 1.8, which is higher than that for total iron.

Copper. Dissolved copper was detected in all samples at a mean concentration of 0.00066 mg/L. The CV for dissolved copper was 0.93.

Zinc. Dissolved zinc was detected in all samples at a mean concentration of 0.002 mg/L. The CV for dissolved zinc was 0.52, the lowest variability among detected dissolved trace elements in lake surface water samples.

Lead. The FOD for dissolved lead was 68 percent. Lead was detected at a mean concentration of 0.00011 mg/L. The CV for dissolved lead was 0.99.

Cadmium. Dissolved cadmium was not detected in any samples.

Arsenic. The FOD for dissolved arsenic was 47 percent. Arsenic was detected at a mean concentration of 0.00068 mg/L. The CV for dissolved arsenic was 2.07, which indicates high variability relative to other dissolved trace elements.

Nickel. The FOD for dissolved nickel was 79 percent. Nickel was detected at a mean concentration of 0.00037 mg/L. The CV for dissolved nickel was 0.67.

Molybdenum. The FOD for dissolved molybdenum was 89 percent. Molybdenum was detected at a mean concentration of 0.00037 mg/L. The CV for dissolved molybdenum was 1.17.

Manganese. Dissolved manganese was detected in all samples at a mean concentration of 0.019 mg/L. The CV for dissolved manganese was 2.16, the highest variability across the dissolved trace elements in lake surface water.

Cyanides

Total Cyanide. The FOD for total cyanide was 2 percent. Total cyanide was detected in only one sample at a mean concentration of 0.00078 mg/L, which is below MRLs and MRLs and indicates the mean concentration is primarily a function of detection limits. The CV for total cyanide was 0.23.

WAD Cyanide. The FOD for WAD cyanide was 9 percent. WAD cyanide was detected at a mean concentration of 0.00099 mg/L, which is below MRLs and MRLs and indicates the mean concentration is primarily a function of detection limits. The CV for WAD cyanide was 0.73.

Organic Compounds

Organic compounds were not analyzed in lake samples.

9.1.10.2. Results and Discussion: Frying Pan Lake

This section presents the findings of the water quality study at Frying Pan Lake, located south of the deposit area, and drained by a tributary to the South Fork Koktuli River (Figure 9.1-5). Surface water samples and measurement of various constituents were obtained to assess the variability of field and

physical parameters, major ions, nutrients, trace elements, and cyanides in the lake. The analysis was conducted using data acquired during the 2006 and 2007 seasons.

As shown in Table 9.1-32, 11 surface water samples were collected from Frying Pan Lake. The number of data points differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, and cyanides.

Field and Physical Parameters

Eight field and physical parameters were measured in Frying Pan Lake surface water samples, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-32. The overall CV for field and physical parameters was 0.58, which is lower than the overall CV across all lakes and ponds. This indicates that water in Frying Pan Lake is more consistent in levels of field and physical parameters than across different lakes.

Total Dissolved Solids. TDS had a mean concentration of 44.3 mg/L. The CV for TDS was 0.26.

pH (Field). The mean concentration for pH was 6.32. The CV for pH was 0.18. The median concentration for pH was 6.26, indicating the water is slightly acidic. The pH is approximately 0.5 pH units lower than the pH in South Fork Koktuli River.

Dissolved Oxygen. DO was detected at a mean concentration of 7.37 mg/L, which is the lowest concentration of all lakes in the study. The CV for DO was 0.14.

Water Temperature. The mean water temperature was 9.09^{o}C. The CV for water temperature was 0.4. Water temperature is cooler in Frying Pan Lake relative to the overall lakes dataset, with a median temperature of 9.62^{o}C compared to 11.6^{o}C in all lakes.

Specific Conductivity (Field). The mean concentration for specific conductivity was 38.2 uS/cm. The CV for specific conductivity was 0.45.

Turbidity. The mean concentration for turbidity was 1.98 NTU, which is slightly higher than for the lakes dataset as a whole. The CV for turbidity was 1.14.

Total Suspended Solids. The FOD for TSS was 91 percent. TSS was detected at a mean concentration of 4.27 mg/L. The CV for TSS was 1.39. TSS is higher in Frying Pan Lake relative to the overall lakes dataset.

Oxidation Reduction Potential. ORP was detected at a mean concentration of 128 mV and ranged from -77.8 mV to 223 mV. The CV for ORP was 0.7.

Major Ions

Frying Pan Lake data for nine parameters (calcium, magnesium, sodium, and potassium [dissolved and total], as well as alkalinity, sulfate, chloride, fluoride, and hardness [not filtered]) are discussed in this

section and summarized in Table 9.1-32. Data for the other analyzed parameters in this group (e.g., total acidity and ion balance) can be found in Appendix 9.1L.

All of the major ions except fluoride (64 percent FOD) were detected in all samples. Calcium and sulfate were detected at the highest mean concentrations of the individual ions in this group of constituents; fluoride had a mean concentration one or two orders of magnitude lower than the other major ions (Table 9.1-32).

The overall CV for the major ions was 0.46, indicating relatively low variability in concentrations of these parameters relative to trace elements.

Calcium (Total). Total calcium was detected at a mean concentration of 5.02 mg/L, making it the most abundant major ion in Frying Pan Lake. The CV for total calcium was 0.38.

Calcium (Dissolved). Dissolved calcium was detected at a mean concentration of 4.78 mg/L. The CV for dissolved calcium was 0.37.

Magnesium (Total). Total magnesium was detected at a mean concentration of 1.09 mg/L. The CV for total magnesium was 0.56.

Magnesium (Dissolved). Dissolved magnesium was detected at a mean concentration of 1.05 mg/L. The CV for dissolved magnesium was 0.55.

Sodium (Total). Total sodium was detected at a mean concentration of 2.19 mg/L, making it the third most abundant major ion in Frying Pan Lake. The CV for total sodium was 0.22.

Sodium (Dissolved). Dissolved sodium was detected at a mean concentration of 2.18 mg/L. The CV for dissolved sodium was 0.19.

Potassium (Total). Total potassium was detected at a mean concentration of 0.2 mg/L. The CV for total potassium was 0.59.

Potassium (Dissolved). Dissolved potassium was detected at a mean concentration of 0.2 mg/L. The CV for dissolved potassium was 0.59. Dissolved and total potassium have almost identical values in Frying Pan Lake.

Alkalinity, Total. Total alkalinity had a mean concentration of 19.8 mg/L, which is similar to the overall lakes dataset. The CV for total alkalinity was 0.35.

Sulfate. Sulfate was detected at a mean concentration of 3.56 mg/L, making it the second most abundant major ion in Frying Pan Lake. The CV for sulfate was 1.07.

Chloride. Chloride was detected at a mean concentration of 0.54 mg/L. The CV for chloride was 0.22, which is the lowest variability across the major ions.

Fluoride. The FOD for fluoride was 64 percent. Fluoride was detected at a mean concentration of 0.038 mg/L, which is below MRLs and indicates the mean concentration is, in part, a function of detection limits and estimated values. The CV for fluoride was 0.52.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected at a mean concentration of 17 mg/L. The CV for hardness as $CaCO_3$ (not filtered) was 0.43. The low hardness value indicates the water in Frying Pan Lake is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-32. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1L.

Total phosphorus was detected in all samples from Frying Pan Lake. Nitrate+nitrite as N was detected in 82 percent of samples, and nitrogen, and total ammonia (as N) was detected in 64 percent of samples. Total orthophosphate [as P] was not detected in any of the samples.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.60 (total phosphorus) to 1.32 (nitrate+nitrite as N). The CV for all nutrients was 0.68, which is lower than the CV for nutrients across other evaluated lakes and ponds combined.

Total Ammonia (as N). The FOD for total ammonia (as N) was 64 percent. Total ammonia (as N) was detected at a mean concentration of 0.071 mg/L, which is below MRLs; therefore, the mean is a function of detection limits and estimated values. The CV for total ammonia (as N) was 0.83.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 82 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.28 mg/L. The CV for total nitrate+nitrite (as N) was 1.32.

Phosphorus. Phosphorus was detected in all 11 samples from Frying Pan Lake at a mean concentration of 0.023 mg/L, which is above both MRLs and MDLs. The CV for phosphorus was 0.60.

Total Orthophosphate (as P). Orthophosphate was not detected in any lake samples.

Total Trace Elements

Frying Pan Lake data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-32 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1L.

Total aluminum, barium, iron, copper, zinc, and manganese were detected in all samples from Frying Pan Lake. Total cadmium was the only trace element not detected in any Frying Pan Lake samples. Total iron was detected at the highest concentrations, with a mean of 0.40 mg/L. Mean concentrations of all other constituents were one to two orders of magnitude lower, ranging from 0.053 mg/L for total aluminum to 0.00011 mg/L for total lead.

The overall CV for total trace elements in Frying Pan Lake surface water samples was 0.81, which is lower than that of the overall lakes dataset. This is consistent with the expectation that samples from a single lake should be more consistent that those across multiple lakes.

Aluminum. Total aluminum was detected in all samples at a mean concentration of 0.053 mg/L, representing the second most abundant total trace element in Frying Pan Lake. The CV for total aluminum was 1.0.

Barium. Total barium was detected in all samples at a mean concentration of 0.004 mg/L. The CV for total barium was 0.44.

Iron. Total Iron was detected in all samples at a mean concentration of 0.40 mg/L and is the most abundant trace element in Frying Pan Lake. The CV for total iron was 0.69.

Copper. Total copper was detected in all samples at a mean concentration of 0.0013 mg/L. The CV for total copper was 1.1.

Zinc. Total zinc was detected in all samples at a mean concentration of 0.0032 mg/L. The CV for total zinc was 0.51.

Lead. The FOD for total lead was 36 percent. Lead was detected at a mean concentration of 0.00011 mg/L. The CV for total lead was 1.27, which is the highest among the total trace elements in Frying Pan Lake.

Cadmium. Total cadmium was not detected in any samples.

Arsenic. The FOD for total arsenic was 45 percent. Arsenic was detected at a mean concentration of 0.00048 mg/L, which is below MRLs. The mean concentration is a function of detection limits and estimated values. The CV for total arsenic was 0.85.

Nickel. The FOD for total nickel was 45 percent. Nickel was detected at a mean concentration of 0.00022 mg/L. The CV for total nickel was 0.69.

Molybdenum. The FOD for total molybdenum was 73 percent. Molybdenum was detected at a mean concentration of 0.00035 mg/L. The CV for total molybdenum was 0.8.

Manganese. Total manganese was detected in all samples at a mean concentration of 0.035 mg/L, representing the third most abundant total trace element in Frying Pan Lake. The CV for total manganese was 0.73.

Dissolved Trace Elements

Frying Pan Lake data for dissolved aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-32 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1L.

Dissolved aluminum, barium, copper, zinc, lead, nickel, and manganese were detected in all samples from Frying Pan Lake. Dissolved cadmium was the only parameter not detected in any Frying Pan Lake samples. Dissolved iron was detected at the highest concentrations, with a mean of 0.16 mg/L. Mean concentrations of other constituents were one to two orders of magnitude lower, ranging from 0.017 mg/L for manganese to 0.00016 mg/L for lead.

The overall CV for dissolved trace elements in Frying Pan Lake surface water samples was 0.66.

Aluminum. Dissolved aluminum was detected in all samples at a mean concentration of 0.015 mg/L. The CV for dissolved aluminum was 0.48.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0033 mg/L. The CV for dissolved barium was 0.46.

Iron. The FOD for dissolved iron was 91 percent. Iron was detected at a mean concentration of 0.16 mg/L, the most abundant dissolved trace element in Frying Pan Lake. The CV for dissolved iron was 0.83.

Copper. Dissolved copper was detected in all samples at a mean concentration of 0.00083 mg/L. The CV for dissolved copper was 0.99.

Zinc. Dissolved zinc was detected in all samples at a mean concentration of 0.0027 mg/L. The CV for dissolved zinc was 0.39.

Lead. Dissolved lead was detected in all samples at a mean concentration of 0.00016 mg/L. The mean is below the range of MRLs and MDLs, indicating it is a function of estimated values. The CV for dissolved lead was 0.47.

Cadmium. Dissolved cadmium was not detected in any samples.

Arsenic. The FOD for dissolved arsenic was 45 percent. Arsenic was detected at a mean concentration of 0.00036 mg/L, which is below MRLs. The mean concentration is a function of detection limits and estimated values. The CV for dissolved arsenic was 0.77.

Nickel. Dissolved nickel was detected in all samples at a mean concentration of 0.00036 mg/L for the two samples in which it was reported. The CV for dissolved nickel was 0.35.

Molybdenum. The FOD for dissolved molybdenum was 73 percent. Molybdenum was detected at a mean concentration of 0.00035 mg/L. The CV for dissolved molybdenum was 0.82.

Manganese. Dissolved manganese was detected in all samples at a mean concentration of 0.017 mg/L. The CV for dissolved manganese was 1.04.

Cyanides

Total Cyanide. Total cyanide was not detected in any sample.

WAD Cyanide. WAD cyanide was detected in three samples (27 percent FOD). WAD cyanide was detected at a mean concentration of 0.0013 mg/L, which is below both MRLs and MDLs. The mean is a function of detection limits and estimated values. The CV for WAD cyanide was 0.99.

Organic Compounds

Organic compounds were not analyzed in any Frying Pan Lake samples.

Comparison with Water Quality Criteria

Field and physical parameters, ions, trace elements, and cyanide concentrations were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison is presented in Table 9.1-33. Concentrations of most constituents met the most stringent water quality criteria. Concentrations were outside of the most stringent criteria in at least one sample for the following constituents:

- pH was outside the criteria range in 9 of 10 samples.
- DO was below the most stringent minimum criteria in 5 of 10 samples.
- Alkalinity was below the most stringent minimum criteria in 4 of 11 samples.
- WAD cyanide was above the most stringent maximum criteria in 1 of 11 samples.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates. Concentrations were above the most stringent maximum water quality criteria in at least one sample for the following trace elements:

- Aluminum (total: 2 in 11 samples).
- Copper (total: 4 in 11 samples; dissolved: 3 in 10 samples).
- Iron (total: 1 in 11 samples).
- Lead (total: 2 in 11 samples; dissolved: 1 in 4 samples).

The pH values were either above (greater than 8.5) or below the most stringent criteria (less than 6.5) at all locations.

Because most locations were sampled only once, it is not surprising that the NOCs of trace elements outside the most stringent criteria were from separate locations.

NOCs outside the most stringent criteria largely appear limited in areas within the lake, while pH most likely represents a continuous source of variability throughout the lake.

9.1.10.3. Results and Discussion: Lakes and Ponds Other than Frying Pan Lake

This section presents the findings of the surface water quality study of lakes other than Frying Pan Lake sampled within the mine study area. Surface water samples and measurement of physical and chemical parameters were obtained from multiple lakes to assess the baseline conditions and spatial variability of field and physical parameters, major ions, nutrients, trace elements, and cyanides in the study area. The analysis was conducted using data acquired during 2006 and 2007.

As shown in Table 9.1-34, 36 surface water samples were collected from lakes other than Frying Pan Lake. The number of data points differs slightly among constituents because some data were rejected during data validation, as discussed in Section 9.1.6, Data Reduction.

The following subsections discuss the summary statistics for field and physical parameters, major ions, nutrients, total and dissolved trace elements, and cyanides.

Field and Physical Parameters

Eight field and physical parameters were measured in surface water samples from lakes other than Frying Pan Lake, including TDS, field pH, DO, water temperature, field specific conductivity, turbidity, TSS, and ORP. Ranges, means, and other summary statistics for these field and physical parameters are presented in Table 9.1-34. The overall CV for field and physical parameters was 0.89, which is higher than the overall CV in samples from Frying Pan Lake. This indicates that water across different water bodies is higher in variability than water from Frying Pan Lake.

Total Dissolved Solids. The FOD for TDS was 97 percent. TDS had a mean concentration of 41.1 mg/L. The CV for TDS was 0.56.

pH (Field). The mean pH was 7.42. The CV for pH was 0.084. The median field pH was 7.48 (pH units), indicating the water is slightly basic. This is different from the neutral to slightly acidic-trending pH in the rivers and creeks within the study area, and the slightly acidic pH in Frying Pan Lake.

Dissolved Oxygen. DO was detected at a mean concentration of 8.84 mg/L, which is similar to the mean in Frying Pan Lake. The CV for DO was 0.24.

Water Temperature. The mean water temperature was 12.8^{o}C. The CV for water temperature was 0.27. With a median temperature of 11.9^{o}C, water temperature is about 7 or 8 degrees warmer in lakes than in rivers or creeks within the study area, and about 2 degrees warmer than Frying Pan Lake. Most of the other sampled lakes are smaller than Frying Pan Lake, which could account for the higher annual water temperatures in these other lakes.

Specific Conductivity (Field). The mean concentration for specific conductivity was 68.2 uS/cm. The CV for specific conductivity was 1.71.

Turbidity. Turbidity is generally low in the study area for lakes as indicated by the mean concentration of 1.54 NTU, but above the mean concentration in Frying Pan Lake. The CV for turbidity was 0.96.

Total Suspended Solids. TSS was detected in all samples at a mean concentration of 2.68 mg/L, which is lower than that in Frying Pan Lake. The CV for TSS was 1.42.

Oxidation Reduction Potential. ORP was detected at a mean concentration of 49.8 mV, with a range between -75 mV and 223 mV. The CV for ORP was 2.21, the highest variability across this group of constituents.

Major Ions

Data for nine parameters (calcium, magnesium, sodium, and potassium (dissolved and total), as well as alkalinity, sulfate, chloride, fluoride, and hardness [not filtered]) are discussed in this section and

summarized in Table 9.1-34. Data for the other analyzed parameters in this group (e.g., total acidity and ion balance) can be found in Appendix 9.1L.

All of the major ions except total potassium (97 percent FOD), alkalinity (86 percent FOD), sulfate (97 percent FOD), and fluoride (47 percent FOD) were detected in all samples. Calcium and sulfate were detected at the highest mean concentrations of the individual ions in this group of parameters; fluoride had a mean concentration one or two orders of magnitude lower than the other major ions (Table 9.1-34). Sulfate is higher in this dataset than in either the overall lake dataset or the dataset representing lakes other than Frying Pan Lake.

The overall CV for the major ions was 0.77, indicating relatively low variability in concentrations of these parameters relative to trace elements for the same samples in these lakes. This CV is higher than that for Frying Pan Lake.

Calcium (Total). Total calcium was detected in all samples at a mean concentration of 5.97 mg/L and is the most abundant major ion in lakes other than Frying Pan Lake in the study area. The CV for total calcium was 0.7.

Calcium (Dissolved). Dissolved calcium was detected in all samples at a mean concentration of 6.09 mg/L and is the most abundant major ion in lakes other than Frying Pan Lake in the study area. The CV for dissolved calcium was 0.65.

Magnesium (Total). Total magnesium was detected in all samples at a mean concentration of 1.32 mg/L. The CV for total magnesium was 0.78.

Magnesium (Dissolved). Dissolved magnesium was detected in all samples at a mean concentration of 1.36 mg/L. The CV for dissolved magnesium was 0.72.

Sodium (Total). Total sodium was detected in all samples at a mean concentration of 2.64 mg/L. The CV for total sodium was 0.90.

Sodium (Dissolved). Dissolved sodium was detected in all samples at a mean concentration of 2.62 mg/L. The CV for dissolved sodium was 0.85.

Potassium (Total). The FOD for total potassium was 97 percent. Potassium was detected at a mean concentration of 0.33 mg/L. The CV for total potassium was 0.57.

Potassium (Dissolved). Dissolved potassium was detected in all samples at a mean concentration of 0.33 mg/L. The CV for dissolved potassium was 0.54.

Alkalinity, Total. The FOD for total alkalinity was 86 percent. Alkalinity was detected at a mean concentration of 18.1 mg/L. The CV for total alkalinity was 0.68.

Sulfate. The FOD for sulfate was 97 percent. Sulfate was detected at a mean concentration of 5.6 mg/L, which is second in abundance of major ions in these lakes. The CV for sulfate was 1.85, indicating relatively high variability for this constituent.

Chloride. Chloride was detected in all samples at a mean concentration of 0.52 mg/L. The CV for chloride was 0.40.

Fluoride. The FOD for fluoride was 47 percent. Fluoride was detected at a mean concentration of 0.030 mg/L, which is below both MRLs and MDLs. The mean is a function of detection limits and estimated values. The CV for fluoride was 0.61.

Hardness as $CaCO_3$ (Not Filtered). Hardness as $CaCO_3$ (not filtered) was detected in all samples at a mean concentration of 20.3 mg/L. The CV for hardness as $CaCO_3$ (not filtered) was 0.7. The low hardness value indicates the water is soft relative to the default of 50 mg/L used to develop water quality criteria.

Nutrients

Data for four parameters (total ammonia, nitrogen [as N]; total nitrate+nitrite [as N]; phosphorus; and phosphorus, total orthophosphate [as P]) are discussed in this section and summarized in Table 9.1-34. Data for other analyzed parameters in this group (e.g., nitrogen-nitrate [as N] and nitrogen, nitrite) can be found in Appendix 9.1L.

Total phosphorus was detected in 97 percent of samples from lakes other than Frying Pan Lake, nitrate+nitrite as N was detected in 47 percent of samples, and nitrogen, and total ammonia (as N) was detected in 28 percent of samples. Total orthophosphate [as P] was not detected in any of the samples.

The variability of analytical data for nutrients was higher than major ions, with CVs ranging from 0.65 (total phosphorus) to 0.88 (nitrate+nitrite as N). The CV for all nutrients was 0.75, which is slightly higher than the CV for nutrients in Frying Pan Lake.

Total Ammonia, as N. The FOD for total ammonia was 28 percent. Total ammonia was detected at a mean concentration of 0.029 mg/L, which is below both MRLs and MDLs. The mean is a function of detection limits and estimated values. The CV for total ammonia was 0.74.

Total Nitrate+Nitrite (as N). The FOD for total nitrate+nitrite (as N) was 47 percent. Total nitrate+nitrite (as N) was detected at a mean concentration of 0.060 mg/L, which is below MRLs. The mean is a function of detection limits and estimated values. The CV for total nitrate+nitrite (as N) was 0.88.

Phosphorus. The FOD for phosphorus was 97 percent. Phosphorus was detected at a mean concentration of 0.021 mg/L, which is above MRLs and MDLs. The CV for phosphorus was 0.65.

Total Orthophosphate (as P). Total orthophosphate (as P) was not detected in any lake samples.

Total Trace Elements

Data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-34 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1L.

Total aluminum, barium, copper, and manganese were detected in all samples from lakes other than Frying Pan Lake. Iron, zinc, and molybdenum were detected in over 90 percent of samples. Total

cadmium was the only parameter not detected in any lake samples (including Frying Pan Lake). Total iron was detected at the highest concentration, with a mean of 0.34 mg/L. Mean concentrations of all other constituents were lower, ranging from 0.065 mg/L for total aluminum to 0.00020 mg/L for total lead.

The overall CV for total trace elements in surface water samples from other lakes (1.29) was higher than that for Frying Pan Lake, likely due to variability among different lakes.

Aluminum. Total aluminum was detected in all samples at a mean concentration of 0.065 mg/L and represents the second most abundant total trace element in this dataset. The CV for total aluminum was 1.31.

Barium. Total barium was detected in all samples at a mean concentration of 0.0042 mg/L. The CV for total barium was 0.82.

Iron. The FOD for total iron was 94 percent. Iron was detected at a mean concentration of 0.34 mg/L, which is the most abundant trace element in the dataset. The CV for total iron was 1.55, which indicates relatively high variability for this constituent.

Copper. Total copper was detected in all samples at a mean concentration of 0.00066 mg/L. The CV for total copper was 1.06.

Zinc. The FOD for total zinc was 97 percent. Zinc was detected at a mean concentration of 0.0029 mg/L, which is just below MDLs, indicating the mean is, in part, a function of detection limits and estimated concentrations. The CV for total zinc was 0.97.

Lead. The FOD for total lead was 69 percent. Lead was detected at a mean concentration of 0.0002 mg/L. The CV for total lead was 1.16.

Cadmium. Cadmium was not detected in any samples.

Arsenic. The FOD for total arsenic was 50 percent. Arsenic was detected at a mean concentration of 0.00086 mg/L. The CV for total arsenic was 1.88, which is relatively high variability for total trace elements in this dataset.

Nickel. The FOD for total nickel was 86 percent. Nickel was detected at a mean concentration of 0.00032 mg/L. The CV for total nickel was 0.88.

Molybdenum. The FOD for total molybdenum was 94 percent. Molybdenum was detected at a mean concentration of 0.00039 mg/L. The CV for total molybdenum was 1.25.

Manganese. Total manganese was detected in all samples at a mean concentration of 0.028 mg/L, which is the third most abundant total trace element in the dataset. The CV for total manganese was 2.04, which is the highest variability across the total trace elements in this dataset.

Dissolved Trace Elements

Data for aluminum, barium, iron, copper, zinc, lead, cadmium, arsenic, nickel, molybdenum, and manganese are summarized in Table 9.1-34 and discussed below. Other trace elements were also analyzed (antimony, beryllium, bismuth, boron, chromium, cobalt, mercury, selenium, silver, thallium, tin, and vanadium). Data for these other trace elements are presented in Appendix 9.1L.

Dissolved aluminum, barium, copper, zinc, and manganese were detected in all samples from lakes other than Frying Pan Lake, and molybdenum was detected in 94 percent of samples. Dissolved cadmium was the only parameter not detected in any lake samples (including Frying Pan Lake). Dissolved iron was detected at the highest concentrations, with a mean concentration of 0.17 mg/L. Mean concentrations of all other constituents were at least one order of magnitude lower, ranging from 0.022 mg/L for aluminum to 0.00011 mg/L for lead.

Similar to total trace elements, the overall CV for dissolved trace elements in surface water samples from other lakes (1.31) was higher than that for Frying Pan Lake, likely due to variability across different lakes.

Aluminum. Dissolved aluminum was detected in all samples at a mean concentration of 0.022 mg/L, which is about one-third the concentration of total aluminum. Dissolved aluminum is the second most abundant trace element in the dataset. The CV for dissolved aluminum was 1.49.

Barium. Dissolved barium was detected in all samples at a mean concentration of 0.0037 mg/L. The CV for dissolved barium was 0.8.

Iron. The FOD for dissolved iron was 89 percent. Iron was detected at a mean concentration of 0.17 mg/L, which is the most abundant of the dissolved trace elements in the dataset. The CV for dissolved iron was 2.0, which is greater than the variability for total iron.

Copper. Dissolved copper was detected in all samples at a mean concentration of 0.00059 mg/L. The CV for dissolved copper was 0.88.

Zinc. Dissolved zinc was detected in all samples at a mean concentration of 0.0018 mg/L. The CV for dissolved zinc was 0.53, which was lower than the CV for total zinc.

Lead. The FOD for dissolved lead was 64 percent. Lead was detected at a mean concentration of 0.00011 mg/L. The CV for dissolved lead was 1.08.

Cadmium. Cadmium was not detected in any samples.

Arsenic. The FOD for dissolved arsenic was 47 percent. Arsenic was detected at a mean concentration of 0.00078 mg/L. The CV for dissolved arsenic was 2.05.

Nickel. The FOD for dissolved nickel was 78 percent. Nickel was detected at a mean concentration of 0.00037 mg/L. The CV for dissolved nickel was 0.69.

Molybdenum. The FOD for dissolved molybdenum was 94 percent. Molybdenum was detected at a mean concentration of 0.00038 mg/L. The CV for dissolved molybdenum was 1.25.

Manganese. Dissolved manganese was detected in all samples at a mean concentration of 0.02 mg/L. The CV for dissolved manganese was 2.34, which reflects the greatest variability across dissolved trace elements in the dataset.

Cyanides

Total Cyanide. Total cyanide was detected in only one sample (3 percent FOD). Total cyanide was detected at a mean concentration of 0.00078 mg/L, which is below MRLs and MRLs. The mean represents a function of detection limits. The CV for total cyanide was 0.27.

WAD Cyanide. WAD cyanide was also detected in only one sample (3 percent FOD). WAD cyanide was detected at a mean concentration of 0.00089 mg/L, which is below MRLs and MRLs. The mean represents a function of detection limits. The CV for WAD cyanide was 0.47.

Organic Compounds

Organic compounds were not analyzed in any lake samples.

Comparison with Water Quality Criteria

Field and physical parameters, ions, trace elements, and cyanide concentrations for lakes other than Frying Pan Lake were compared against ADEC water quality criteria for the protection of human health and aquatic life (ADEC, 2009), as described in the Comparison with Water Quality Criteria subsection of Section 9.1.8.1.

A summary of the comparison is presented in Table 9.1-35. Concentrations of most constituents met the most stringent water quality criteria. Concentrations were outside the most stringent criteria in at least one sample for the following constituents:

- pH was outside the criteria range in 3 of 36 samples.
- DO was below the most stringent minimum criteria in 6 of 36 samples.
- Alkalinity was below the most stringent minimum criteria in 21 of 36 samples.

The pH values were below the minimum criterion at one location in 2006, and above the maximum criterion in 2007. This most likely represents a continuous source of variability across the lakes. Similarly, DO and alkalinity concentrations are naturally below minimum criteria at multiple lakes, indicating the source of variability may be natural and occurs sporadically in lakes for these constituents.

Water quality criteria for several NOCs (cadmium, copper, lead, nickel, and zinc) are hardness-dependent because the toxicity is partially based on the binding ability of the water. Other aquatic life criteria are pH-, and/or temperature-dependent. Input values used for chemical-specific hardness adjusted criteria equations are provided in Table 9.1-9, and adjusted preliminary values are provided in Appendix 9.1B. These preliminary estimates were used for comparative purposes based on a range of baseline hardness values throughout the drainage. Criteria for cadmium, copper, lead, nickel, and zinc are all based on these preliminary estimates. Concentrations were above the most stringent maximum water quality criteria in at least one sample for the following trace elements: Aluminum (total: 7 of 36 samples; dissolved: 2 of 36 samples).

- Cadmium (total: 1 of 36 samples; dissolved: 1 of 36 samples; based on the default value for non-detected samples of one –half of the detection limit).

- Copper (total: 6 of 36 samples; dissolved: 4 of 26 samples).
- Iron (total: 4 of 36 samples; dissolved: 2 of 36 samples).
- Lead (total: 11 of 36 samples; dissolved: 4 of 33 samples).
- Manganese (total: 4 of 36 samples).
- Zinc (total: 1 of 36 samples).

As discussed above, sources of variability demonstrate that NOCs of several trace elements are above the most stringent maximum criteria sporadically across different lakes in the mine study area.

9.1.10.4. Comparison Between Lake and Pond Datasets

Total concentrations of detected parameters in Frying Pan Lake and other lakes combined were compared using the Mann-Whitney U-Test, a non-parametric version of the two-sample *t*-test. This test was conducted to evaluate if total and dissolved concentrations were statistically different for individual trace elements between Frying Pan Lake and the other lakes included in the water quality sampling program. This is important because Frying Pan Lake has been the most extensively sampled lake, is located down-gradient from the general deposit area, and is one of the larger lakes in the mine study area. It is therefore useful to understand if Frying Pan Lake can serve as an indicator of baseline conditions across all lakes in the area, or if it has a different signature. Results are presented in Table 9.1-36.

The Mann-Whitney U-Test was also conducted for similar comparisons of concentrations between river systems for both surface water and seep data. For this evaluation, the standard p-value of 0.05 was used to identify parameters with significant differences in concentrations between the datasets. Specific locations were not compared within a lake because the focus of this evaluation was to compare concentrations between datasets rather than different areas within a lake.

As shown in Table 9.1-36, significant differences between at least two pairs were identified for total iron, total potassium, and pH. Potassium is present at significantly higher median concentrations in the other lakes than in Frying Pan Lake, while the opposite is true for iron. The pH value is significantly more basic in the other lakes (mean of 7.4) than in Frying Pan Lake (mean of 6.3).

Results are also shown graphically for each parameter in Figures 9.1-248 through 9.1-268. These graphs compare the medians between the two datasets and illustrate the relative variability of the data medians. The graphs illustrate the significant differences for pH (Figure 9.1-249), potassium (Figure 9.1-252), and iron (Figure 9.1-260). Although not statistically significant, molybdenum (Figure 9.1-266) is present in Frying Pan Lake (0.0028 mg/L) at higher concentrations than in other lakes (0.0016 mg/L). Nickel shows this same trend, but to a lesser extent. Conversely, mean sulfate concentrations in the other lakes were about twice the mean sulfate concentrations in Frying Pan Lake (Figure 9.1-254).

The pH of the other lakes was quite consistent, while the measurements for Frying Pan Lake were more variable (Figure 9.1-249). This is likely because samples were collected from a variety of locations in Frying Pan Lake, incorporating shallow and deep areas as well as areas of high and low sedimentation, while typically only one or two locations were sampled at the other lakes. Therefore, the low variability of pH from the other lakes is, in part, an artifact of the differences in sampling regimes between these lakes and Frying Pan Lake.

These graphs also illustrate that many of the calculated medians were below MRLs, indicating the majority of data points are estimated concentrations. This is the case for four parameters including TSS, fluoride, cyanide, and WAD cyanide.

Based on this evaluation, it is clear that Frying Pan Lake has a different signature of constituents than other lakes included in the water quality program. Because Frying Pan Lake incorporates drainage from upper elevations around the deposit area, this lake is enriched in minerals that result in baseline conditions outside of criteria for a small subset of elements and parameters.

9.1.11. Summary

Between 2004 and 2008, water quality was evaluated for the North Fork Koktuli River, South Fork Koktuli River, Upper Talarik Creek, Kaskanak Creek, seeps within each of the three major drainages, and lakes in the mine study area. Over 1,000 samples were collected across the rivers and creeks, more than 600 samples from seeps, and approximately 50 samples from lakes.

In rivers, concentrations of most constituents differed significantly across drainages. Four of the evaluated field and physical parameters (TDS, pH, alkalinity, and TSS) were significantly different across river systems. Five major ions, including sodium, sulfate, chloride, fluoride, and hardness (as $CaCO_3$), and one nutrient (total nitrate+nitrite [as N]), also differed significantly across river systems. Of the trace elements evaluated, only two (cadmium and lead) were not significantly different across river systems.

These findings are primarily explained by the proximity of South Fork Koktuli River and Upper Talarik Creek sampling locations to the deposit area. The relative ranks (i.e., highest to lowest concentrations) for each waterbody differed by analyte. Sulfate, copper, zinc, nickel, and molybdenum concentrations were greatest in the South Fork Koktuli River, consistent with the headwaters of this river passing through the deposit area and multiple sample locations present in this area. TDS, pH, sodium, alkalinity, hardness, nitrogen (total nitrate+nitrite [as N]), and nickel concentrations were greatest in the Upper Talarik Creek drainage. Significantly higher concentrations of copper, molybdenum, nickel, zinc, and sulfate were also present in the South Fork Koktuli River than in the North Fork Koktuli River, consistent with its proximity to the deposit area. The Upper Talarik, which in the uppermost reach also passes through a portion of the general deposit area, also had significantly higher concentrations of all of these NOCs, except copper, than in the North Fork Koktuli River.

TSS, potassium, chloride, iron, and arsenic concentrations were highest in Kaskanak Creek, while cadmium and lead concentrations were highest in the North Fork Koktuli River drainage. This most likely indicates these parameters are unrelated to the general deposit area and represent different signatures than the other drainage areas.

Many NOCs, particularly trace elements, exhibited seasonal patterns of higher concentrations across all three main river systems during periods associated with snowmelt in the spring and heavy rains in the fall. Fewer NOCs, primarily major ions, showed either small or no differences seasonally.

In seeps, five ions were consistently most abundant and had the highest mean concentrations in the seep water collected in all three drainages. These include total and dissolved sodium, magnesium, potassium, calcium, and sulfate. In general, mean concentrations of trace metals were lowest in seeps located in the North Fork Koktuli River drainage. The highest concentrations were divided between seeps located in the

South Fork Koktuli River and Upper Talarik Creek drainages, likely due to their partial proximity to the general deposit area. Trace elements of particular note are the wide range of aluminum and copper concentrations. Total aluminum concentrations from North Fork Koktuli seep samples had a mean of 0.025 mg/L, while total aluminum from South Fork Koktuli seep samples had a mean of 0.50 mg/L. Total copper concentrations from North Fork Koktuli seep samples had a mean of 0.00037 mg/L, and total copper concentrations from South Fork Koktuli seep samples had a mean of 0.12 mg/L.

Major ion and trace element concentrations in seeps showed considerable variability within and across the three drainages. The range of concentrations of the constituents in seeps is primarily due to the effect of drainage subsurface water conditions. These drainages differ in geological formation, elevations in relation to the deposit area, presence of binding substances such as ions (i.e., sulfates, chloride ions), suspended and dissolved solids, ORP, water hardness, pH, and groundwater-to-surface water discharge rates.

It appears that peak concentrations in the seeps are related either to: (1) spring snowmelt, or (2) shallow groundwater in the late summer/early fall. This time of year is when aquifers are recharged from precipitation during the summer; water levels drop during the winter.

Concentrations of constituents discharged through seeps are at least, in part, dependent on the water velocity of the seep. Although a few constituents showed direct or inverse relationships with seep flow, the majority had concentrations that appear independent of seep flow. Of the constituents that demonstrated a trend, more exhibit an inverse relationship with flow than a direct one, except in the Upper Talarik drainage.

Frying Pan Lake has a different signature of constituents than other lakes included in the water quality program. Because Frying Pan Lake incorporates drainage from upper elevations around the deposit area, this lake is enriched in minerals that result in baseline conditions outside of criteria for a small subset of elements and parameters.

Based on this evaluation, it is clear that each of the major river systems has significantly different constituent background concentrations, and many constituents vary in concentration both seasonally and across locations.

Key:

C Continuous stage/discharge hydrometric data collected in streams (gaged stations with dataloggers).

F Sediment samples collected.

I Instantaneous stream discharge measurements taken each month coincident with water quality (ungaged stations without dataloggers).

Q Surface-water quality samples collected for field and laboratory analyses.

TABLE 9.1-3
Baseline Surface Water Analytes for Laboratory Determination

Analyte	Method	Method Reporting Limit
Field and Physical Parameters		
Total dissolved solids	E160.1	10 mg/L
Total suspended solids	E160.2	0.5 mg/L
Major Ions		
Calcium, total and dissolved	200.7	50 µg/L
Sodium, total and dissolved	E200.7/200.8	100 µg/L
Potassium, total and dissolved	E200.7/200.8	50 µg/L
Alkalinity	SM20 2320B	10 mg/L
Sulfate	E300.0	0.1 mg/L
Chloride	E300.0	0.1 mg/L
Fluoride	E300.0	0.1 mg/L
Acidity	E305.1	NA
Nutrients		
Total Ammonia - N	E350.2	0.1 mg/L
Nitrate + nitrite	E300.0	0.1 mg/L
Phosphorus - Total Orthophosphate (as P)	E365.2	0.1 mg/L
Trace Elements		
Aluminum, total and dissolved	E200.8	25 µg/L
Antimony, total and dissolved	E200.8	0.2 µg/L
Arsenic, total and dissolved	E200.8	0.5 µg/L
Barium, total and dissolved	E200.8	0.3 µg/L
Beryllium, total and dissolved	E200.8	0.4 µg/L
Bismuth, total and dissolved	E200.8	5 µg/L
Boron, total and dissolved	E200.7	10 µg/L
Cadmium, total and dissolved	E200.8	0.1 µg/L
Chromium, total and dissolved	E200.8	0.2 µg/L
Cobalt, total and dissolved	E200.8	0.1 µg/L
Copper, total and dissolved	E200.8	0.2 µg/L
Iron, total and dissolved	E200.7/200.8	20 µg/L
Lead, total and dissolved	E200.8	0.2 µg/L
Magnesium, total and dissolved	E200.7/200.8	20 µg/L
Manganese, total and dissolved	E200.8	1 µg/L
Mercury, total	E1631	0.001 µg/L
Molybdenum, total and dissolved	E200.8	1 µg/L
Nickel, total and dissolved	E200.8	0.2 µg/L
Selenium, total and dissolved	E200.8	1 µg/L
Silicon, dissolved	E200.7	500 µg/L
Silver, total and dissolved	E200.8	0.2 µg/L
Thallium, total and dissolved	E200.8	0.05 µg/L
Tin, total and dissolved	E200.8	1 µg/L
Vanadium, total and dissolved	E200.8	0.4 µg/L
Zinc, total and dissolved	E200.8	1.5 µg/L

TABLE 9.1-3
Baseline Surface Water Analytes for Laboratory Determination

Analyte	Method	Method Reporting Limit
Cyanides		
Cyanide - total	SM20 4500	0.005 mg/L
Cyanide - WAD	SM20 4500	0.005 mg/L

Key:

E = Environmental Protection Agency (EPA), Methods for Chemical Analysis of Inorganic Substances in Environmental Samples, EPA/600/R-93-100, August 1993, and Methods for the Determination of Metals in Environmental Samples, EPA/600/4-91-010, June.

µg/L = micrograms per liter.

mg/L = milligrams per liter.

NA = not applicable.

SM = American Public Health Association, Standard Methods for the Examination of Water.

SOP = standard operating procedure.

WAD = weak acid dissociable.

TABLE 9.1-4
Rationale for Selection of Seeps Evaluated for Spatial and Temporal Trends

Seep Location	Importance Index	Velocity Category [a]	Electrical Conductivity	Water Quality [b] pH	Water Quality [b] Temperature	Water Quality [b] Water Type	Geology [c] Bedrock	Geology [c] Surface	Watershed	Elevation (ft amsl)	Comments
North Fork Koktuli River Drainage (7 total)											
SP31	Medium	High	Low	Low	Normal		Tert. Volc.	Bedrock	NK	1310-1640	Moderate to high elevation

SP101	High	Medium	Low	Low	Normal		Basalt	Alluv	SK	985-1310	High importance, basalt alluv, low pH
SP104	High	Medium	Very Low	Very Low	High	Mix	Batholith	Bedrock	SK	>1640	High importance, high elevation seep, only one from batholith bedrock
SP112	High	Medium	Moderate	Moderate	Normal	SO4	Silt-Mud	Bedrock	SK	985-1310	High importance, SO4 water type, siltstone - mudstone bedrock

TABLE 9.1-4
Rationale for Selection of Seeps Evaluated for Spatial and Temporal Trends

Seep Location	Importance Index	Velocity Category [a]	Electrical Conductivity	Water Quality [b] pH	Water Quality [b] Temperature	Water Quality [b] Water Type	Geology [c] Bedrock	Geology [c] Surface	Watershed	Elevation (ft amsl)	Comments
Upper Talarik Creek Drainage (12 total)											
SP2 [d]	High	Medium	Low	Moderate	Normal		Tert. Volc.	Bedrock	UT	985-1310	High importance, Tert.volc. Bedrock
SP18 [d]	High	High	Moderate	High	Normal		Q	GL	UT	<655	High importance, good coverage at lower end of catchment
SP40	High	High	Moderate	Moderate	Normal	Mix	Q	Drift	UT	985-1310	High importance, Q drift, UTC area at pit
SP62	High	Medium	Moderate	Low	Normal	Mix	D-P	Drift	UT	985-1310	High importance, D-P drift, low pH
SP66	Medium	Medium	High	Moderate	Normal		Tert. Volc.	Drift	UT	985-1310	High EC, Tert volc.drift
SP73	High	High	Moderate	Moderate	Normal		Batholith	GL	UT	985-1310	High importance, only one in batholith GL
SP75	High	High	Low	Moderate	High		Q	GL	UT	655-985	High importance, high flow, in area where injection may be proposed
SP78	High	High	Moderate	High	Normal	*	Q	GL	UT	655-985	High importance, Q GL, high flow
SP84	High	Medium	Moderate	High	Normal	*	Q	Alluv	UT	<655	High importance, only one in Q alluv
SP108	High	High	Moderate	Moderate	Normal		Q	GL	UT	655-985	High importance, Q GL, high flow
SP109	High	High	Moderate	Moderate	Normal		Q	Drift	UT	<655	High importance, Q drift, high flow
SP116	High	Low	Moderate	Moderate	Normal	Mix	Q	Drift	UT	985-1310	High importance, Q drift, deposit area

Notes:

[a] Velocity categories are defined as follows (in L/s, during low flow season):
Lowest = <0.3 Low = <1 Moderate = 1 to 5 High = >5

[b] Water quality categories are defined as follows:

Electrical Conductivity:	pH:	Temperature (degC):	Water Type:
Very Low = <0.03	Very Low = <5	Normal = 2-4	Mix = HCO3-SO4
Low = <0.05	Low = <6	High = >6.5	Blank = HCO3
Moderate = 0.05-100	Moderate = 6 to 8	Very High = >8.5	* = elevated trace metals (Cu, Mo, As)
High = >100	High = >8		

[c] Geology categories are defined as follows:
Silt-Mud = siltstone, mudstone D-P = diorite and pyroxenite GL = glacio-lacustrine Colluv = colluvium
Tert. Volc. = tertiary volcanics Q = overburden Alluv = alluvium

[d] Seep locations SP1, SP2, and SP18 were excluded from spatial analyses because only field data were available for these locations.

Key:
> = greater than.
degC = degrees Celsius.
ft amsl = feet above mean sea level.
L/s = liters per second.
NK = North Fork Koktuli.
SK = South Fork Koktuli.
µS/cm = microSiemens per centimeter.
UT = Upper Talarik.

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = microSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = microSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

Table 9.1-7
Surface Water Data Summary for Naturally Occurring Constituents, Upper Talarik Creek

Analyte	Frequency of Detection (FOD) [a]	Percent Detected	Range of Detects (Min - Max)	Range of Reporting Limits (MRL) (Min - Max)	Range of Detection Limits (MDL) (Min - Max)	Mean [b]	Median [b]	Standard Deviation [b]	Coefficient of Variation
Organic Compounds (mg/L)									
Dissolved Organic Carbon	181 / 191	95%	0.16 - 8.18	0.50 - 0.50	0.070 - 0.15	1.57	1.29	1.29	0.82

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL - method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = microSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

		Chronic Aquatic Life Criteria	Drinking Water Standards
Total Metals (mg/L)			
Aluminum	233	14	--
Barium	233	--	0
Iron	232	1	--
Copper	232	5	--
Zinc	231	2	--
Lead	232	34	0
Cadmium	233	6	0
Arsenic	233	0	0
Nickel	232	0	0
Molybdenum	232	--	--
Manganese	232	--	6
Antimony	230	--	0
Mercury	230	0	0
Dissolved Metals (mg/L)			
Aluminum	230	0	--
Antimony	218	--	--
Barium	204	--	--
Iron	230	0	--
Copper	164	3	--
Zinc	162	0	--
Lead	192	14	--
Cadmium	230	1	--
Arsenic	231	0	--
Nickel	146	0	--
Molybdenum	209	--	--
Manganese	222	--	--

TABLE 9.1-10
Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, North Fork Koktuli River

Analyte	Number of Samples	Number of Samples Exceeding Criteria [a]	
		Chronic Aquatic Life Criteria	Drinking Water Standards
Cyanides (mg/L)			
Cyanide, Total	232	--	--
Cyanide, Weak Acid Dissociable	232	6	0
Organic Compounds			
Dissolved Organic Carbon	99	--	--

Notes:

[a] Surface water sample results were compared to criteria from ADEC (2008 and 2009). Drinking water standards were compared to total metals data. Chronic aquatic life criteria were compared to both total and dissolved metals data. Hardness-dependent criteria are based on preliminary estimates.

Key:

-- = Not applicable.

TABLE 9.1-11
Upstream to Downstream Sample Location Ranks for Spatial Analyses, North Fork Koktuli River

Location [a]	Rank [b]
NK100D	1
NK100C	2
NK100B	3
NK100A1	4
NK100A	5

Notes:
[a] Only main stem sample locations were included in the upstream to downstream ranking and analyses.
[b] Ranks begin with most upstream location (1 = most upstream, 5 = most downstream).

TABLE 9.1-12

Results of Spatial Regression Analysis of Median Concentrations for Naturally Occurring Constituents in Surface Water, North Fork Koktuli River

Analyte	Regression Significant Different? [a]	p-Value	R^2 Value	Spatial Trend
Field and Physical Parameters (mg/L, except where noted)				
Total Dissolved Solids	**Yes**	**0.04**	**0.816**	Lower downstream
pH (Field, Standard Units)	No	0.10	0.640	None
Total Suspended Solids	No	0.07	0.718	None
Major Ions (mg/L)				
Sodium	No	0.28	0.0070	None
Potassium	**Yes**	**0.013**	**0.903**	Lower downstream
Alkalinity, Total	No	0.75	0.039	None
Sulfate	No	0.88	0	None
Chloride	No	0.67	0.071	None
Fluoride	No	0.68	0.0020	None
Hardness as CaCO3 (Not Filtered)	No	0.74	0.069	None
Nutrients (mg/L)				
Nitrate+Nitrite	No	0.71	0.0010	None
Metals (mg/L)				
Iron	No	0.066	0.729	None
Copper	No	0.19	0.488	None
Zinc	No	0.14	0.574	None
Lead	No	0.75	0.065	None
Cadmium	No	0.19	0.483	None
Arsenic	No	0.48	0.275	None
Nickel	**Yes**	**0.012**	**0.907**	Lower downstream
Molybdenum	No	0.19	0.6580	None
Cyanides (mg/L)				
Cyanide, Total	No	0.45	0.57	None
Cyanide, Weak Acid Dissociable	No	0.13	0.59	None

Notes:

[a] Differences are considered statistically significant if the p-value is less than 0.050. Linear regression analysis was conducted using the median value from each mainstem sample location. Only detected concentrations were included in the median calculations. Locations were ranked from upstream to downstream for the regression analysis.

Bold indicates a statistically significant result.

p-value represents the probability value; values less than 0.05 are considered statistically significant.

R^2 represents the correlation coefficient; the range of values is from 0 (no correlation between variables) and 1 (perfect correlation)

Key:

-- = Not applicable; analyte not detected at sufficient frequency for spatial regression analysis.

TABLE 9.1-20
Differences in Naturally Occurring Constituent Concentrations in Surface Water Across River Systems, Mine Study Area

Analyte	Conduct Pair-wise Comparison? [a]	p-Value	Mean Ranks				Sample Counts			
			NK	SK	UT	KC	NK	SK	UT	KC
Cyanides (mg/L)										
Cyanide, Total	No	0.88	62	68	70	62	17	55	56	6
Cyanide, Weak Acid Dissociable	No	0.15	78	76	68	132	29	59	57	2

Notes:

[a] Analytes were retained for further evaluation if the p-value was less than 0.10. The nonparametric Kruskall-Wallis test was used for statistical comparisons. Only detected concentrations were included in the statistical comparisons.

Bold indicates analytes retained for further evaluation using the pair-wise Mann-Whitney test.

Key:

< = less than.

KC = Kaskanak Creek.

NK = North Fork Koktuli River.

SK = South Fork Koktuli River.

UT = Upper Talarik Creek.

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MD

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = milliSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

TABLE 9.1-23
Surface Water Data Summary for Naturally Occurring Constituents, Seeps in the North Fork Koktuli River Drainage

Analyte	Frequency of Detection (FOD) [a]	Percent Detected	Range of Detects (Min - Max)	Range of Reporting Limits (MRL) (Min - Max)	Range of Detection Limits (MDL) (Min - Max)	Mean [b]	Median [b]	Standard Deviation [b]	Coefficient of Variation
Cyanides (mg/L)									
Cyanide, Total	8 / 104	8%	0.00075 - 0.0041	0.0050 - 0.030	0.0015 - 0.0050	0.0025	0.0025	0.0030	1.21
Cyanide, Weak Acid Dissociable	14 / 103	14%	0.00075 - 0.0080	0.0050 - 0.050	0.0015 - 0.010	0.0023	0.0025	0.0031	1.31

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = milliSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

TABLE 9.1-25
Surface Water Data Summary for Naturally Occurring Constituents, Seeps in the South Fork Koktuli River Drainage

Analyte	Frequency of Detection (FOD) [a]	Percent Detected	Range of Detects (Min - Max)	Range of Reporting Limits (RDL) (Min - Max)	Range of Detection Limits (MDL) (Min - Max)	Mean [b]	Median [b]	Standard Deviation [b]	Coefficient of Variation
Cyanides (mg/L)									
Cyanide, Total	21 / 206	10%	0.00075 - 0.057	0.0050 - 0.10	0.0015 - 0.030	0.0033	0.0025	0.0062	1.87
Cyanide, Weak Acid Dissociable	23 / 206	11%	0.00075 - 0.0040	0.0050 - 0.050	0.0015 - 0.010	0.0025	0.0025	0.0032	1.31

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = milliSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

TABLE 9.1-28
Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Seeps, Upper Talarik Creek Drainage

Analyte	Number of Samples	Number of Samples Exceeding Criteria [a]	
		Chronic Aquatic Life Criteria	Drinking Water Standards
Cyanides (mg/L)			
Cyanide, Total	338	--	--
Cyanide, Weak Acid Dissociable	338	25	0

Notes:
[a] Surface water sample results were compared to criteria from ADEC (2008 and 2009). Drinking water standards were compared to total metals data. Chronic aquatic life criteria were compared to both total and dissolved metals data. Hardness-dependent criteria based on preliminary estimates.

Key:
-- = Not available or not applicable.

Cyanide, Total	0.32	--	--
Cyanide, Weak Acid Dissociable	1.00	0.82	1.00

Notes:

[a] Seep locations and corresponding drainages are shown in Table 9.1-4.

[b] Differences are considered statistically significant if the p-value is less than 0.050.
The nonparametric Mann-Whitney U-test was used for statistical comparisons.
Only detected concentrations were included in the statistical comparisons.

Bold indicates a statistically significant difference.

Key:

-- = Mann-Whitney Test not conducted due to insufficient detection frequency.

< = less than.

NK = North Fork Koktuli Drainage.

SK = South Fork Koktuli Drainage.

UT = Upper Talarik Drainage.

Cyanide, Total	1 / 47	2%	0.0020 - 0.0020	0.0050 - 0.0050	0.0015 - 0.0015	0.00078	0.00075	0.00018	0.23
Cyanide, Weak Acid Dissociable	4 / 47	9%	0.0016 - 0.0050	0.0050 - 0.0050	0.0015 - 0.0015	0.00099	0.00075	0.00072	0.73

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = microSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = microSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

Notes:

[a] Frequency of detection (FOD) = Number of detected samples / total number of samples in data set.

[b] When calculating the average, median, and standard deviation, non-detects with "U" or "UJ" qualifiers were included as one-half the RDL. Non-detect results of zero, without "U" or "UJ" qualifiers, were included as one-half the MDL.

Key:

-- = Not applicable.
degC = degrees Celsius.
MDL = method detection limit.
MEQ/L = milliequivalent per liter.
mg/L = milligram per liter.
uS/cm = microSiemens per centimeter.
mV = millivolt.
NTU = nephelometric turbidity units.
ORP = oxidation reduction potential.
MRL = method reporting limit.

TABLE 9.1-35
Comparison of Human Health and Freshwater Aquatic Life Water Quality Criteria with Naturally Occurring Constituent Concentrations in Surface Water, Lakes in the Mine Study Area Other than Frying Pan Lake

Cyanides (mg/L)			
Cyanide, Total	36	--	--
Cyanide, Weak Acid Dissociable	36	0	0

Notes:
[a] Surface water sample results were compared to criteria from ADEC (2008 and 2009). Drinking water standards were compared to total metals data. Chronic aquatic life criteria were compared to both total and dissolved metals data. Hardness-dependent criteria based on preliminary estimates.
[b] Detection limit exceeds criteria.

Key:
-- = Not available or not applicable.

Total Suspended Solids Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

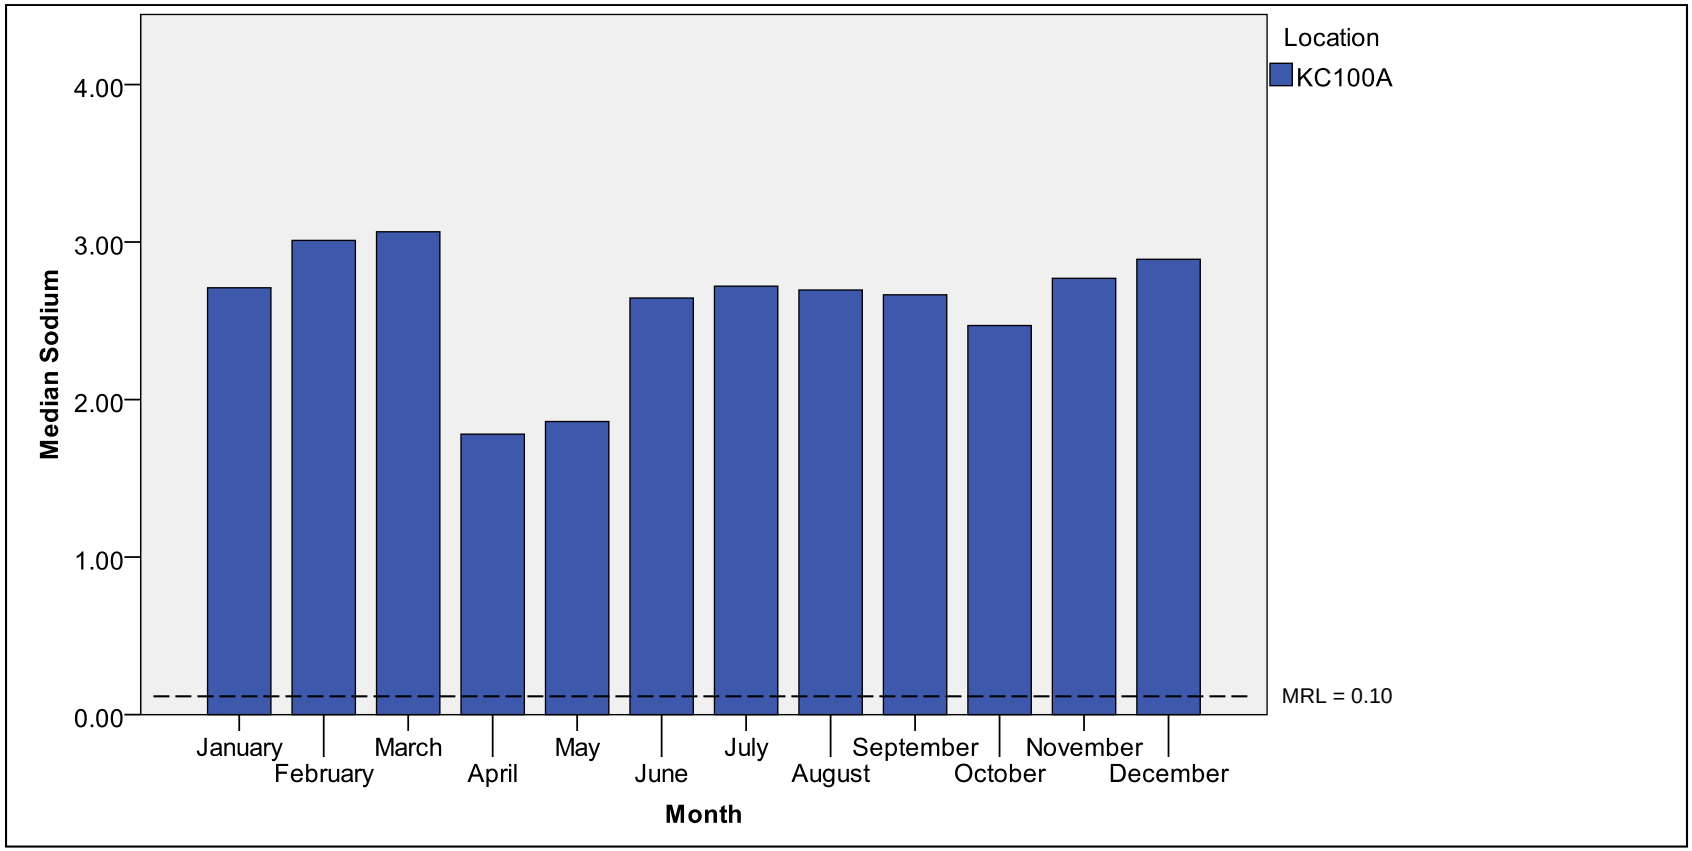

FIGURE 9.1-134
Sodium (Total) Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

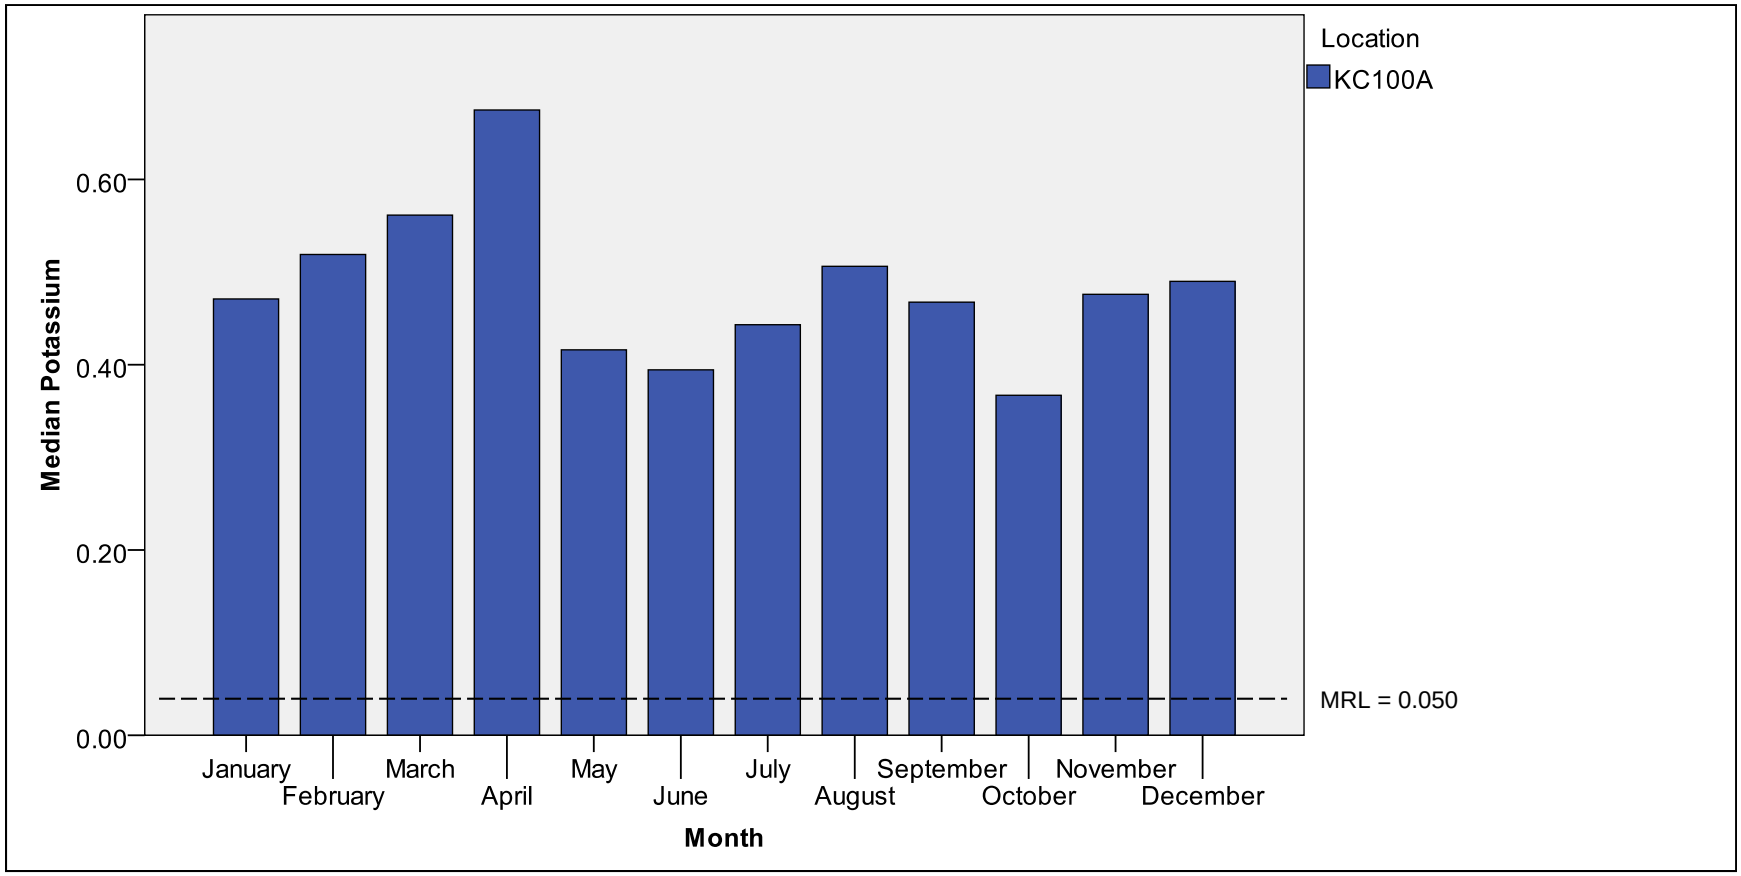

FIGURE 9.1-135
Potassium Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

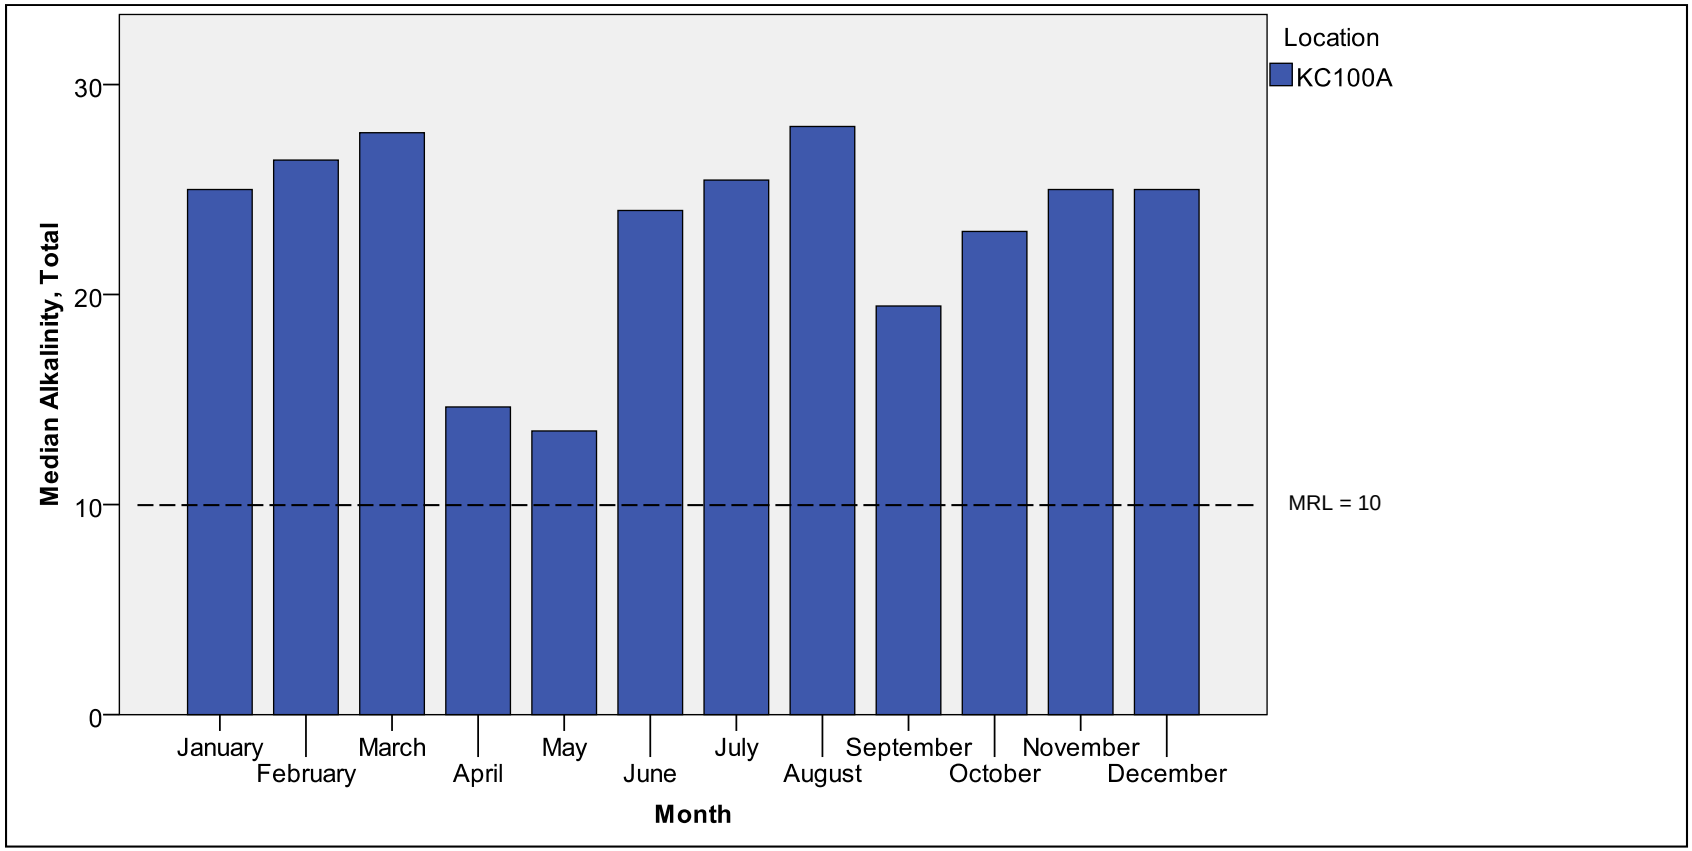

FIGURE 9.1-136
Alkalinity Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

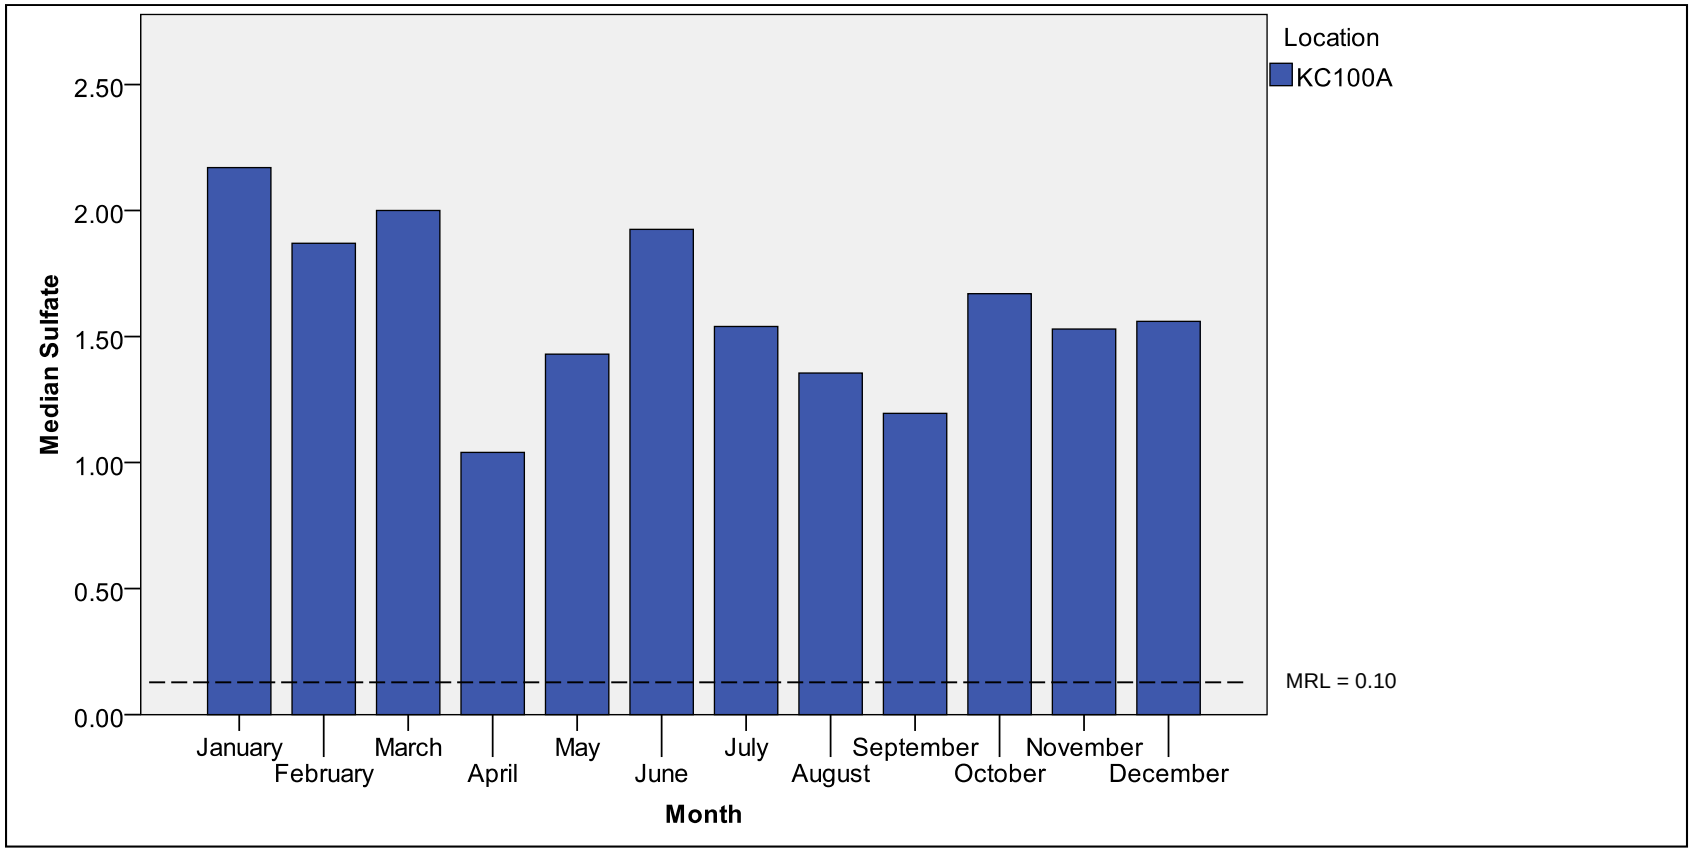

FIGURE 9.1-137
Sulfate Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

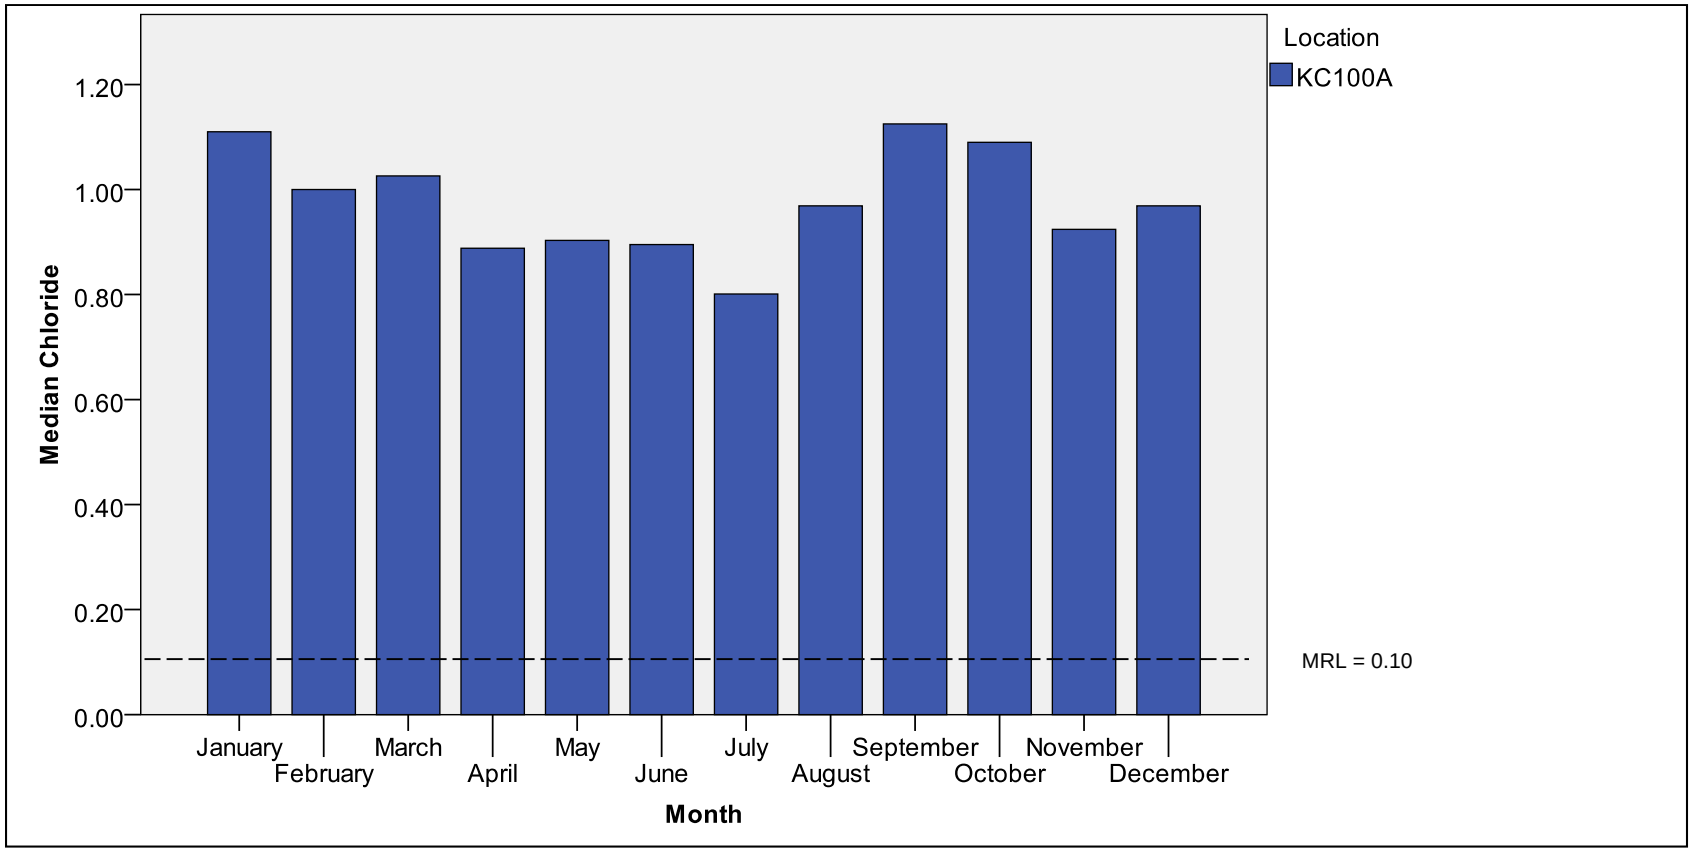

FIGURE 9.1-138
Chloride Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

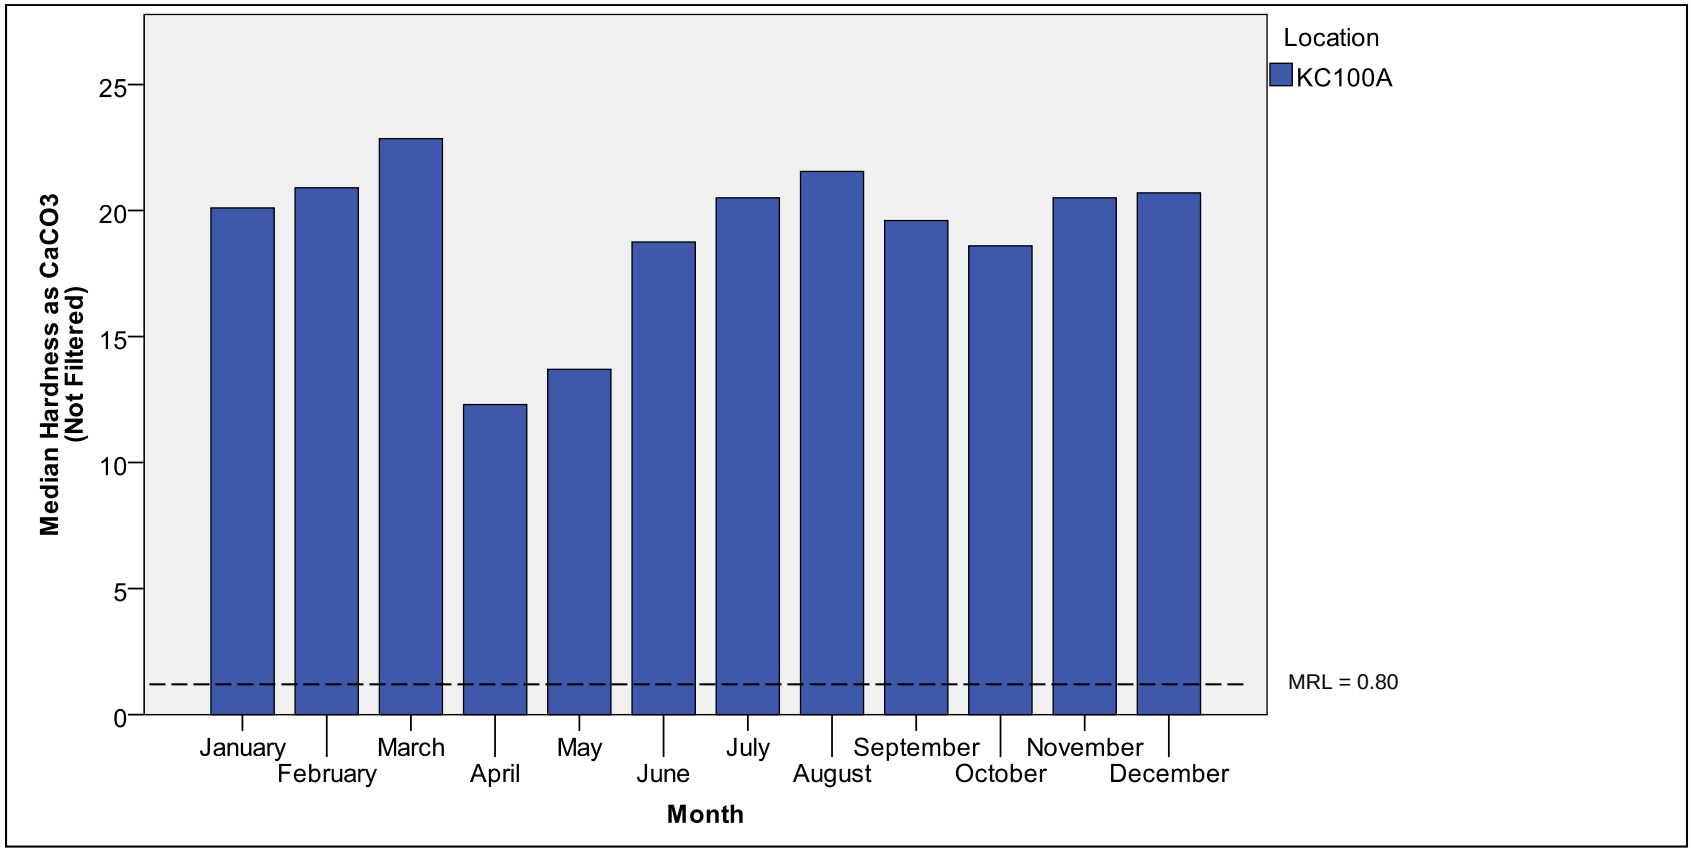

FIGURE 9.1-139
Hardness as $CaCO_3$ (Not Filtered) Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

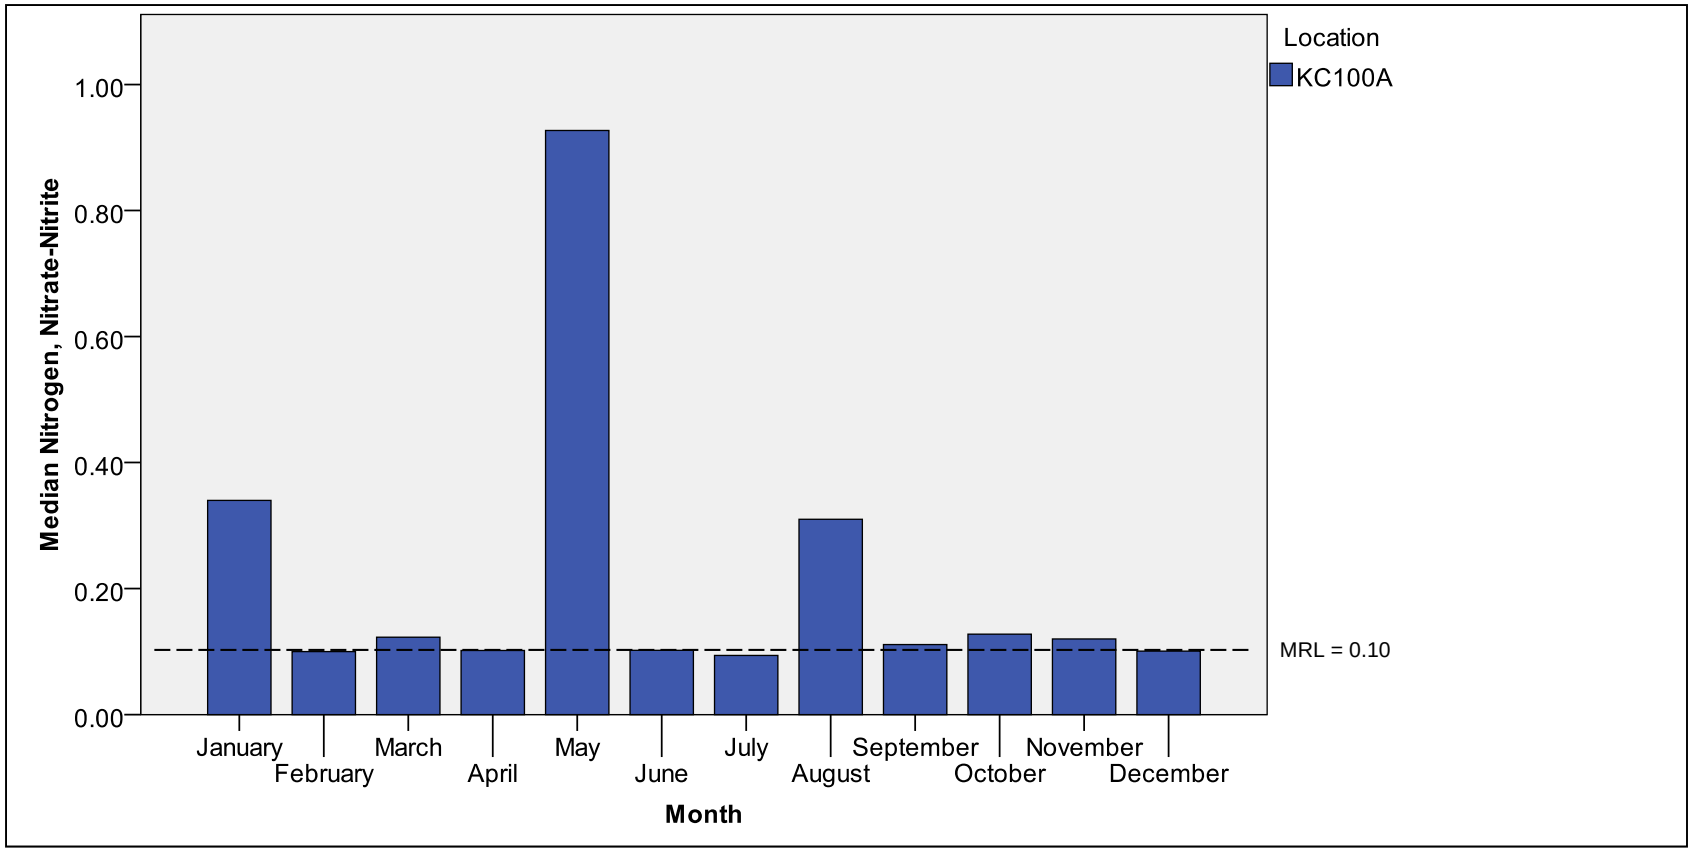

FIGURE 9.1-140
Total Nitrate+Nitrite (as N) Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

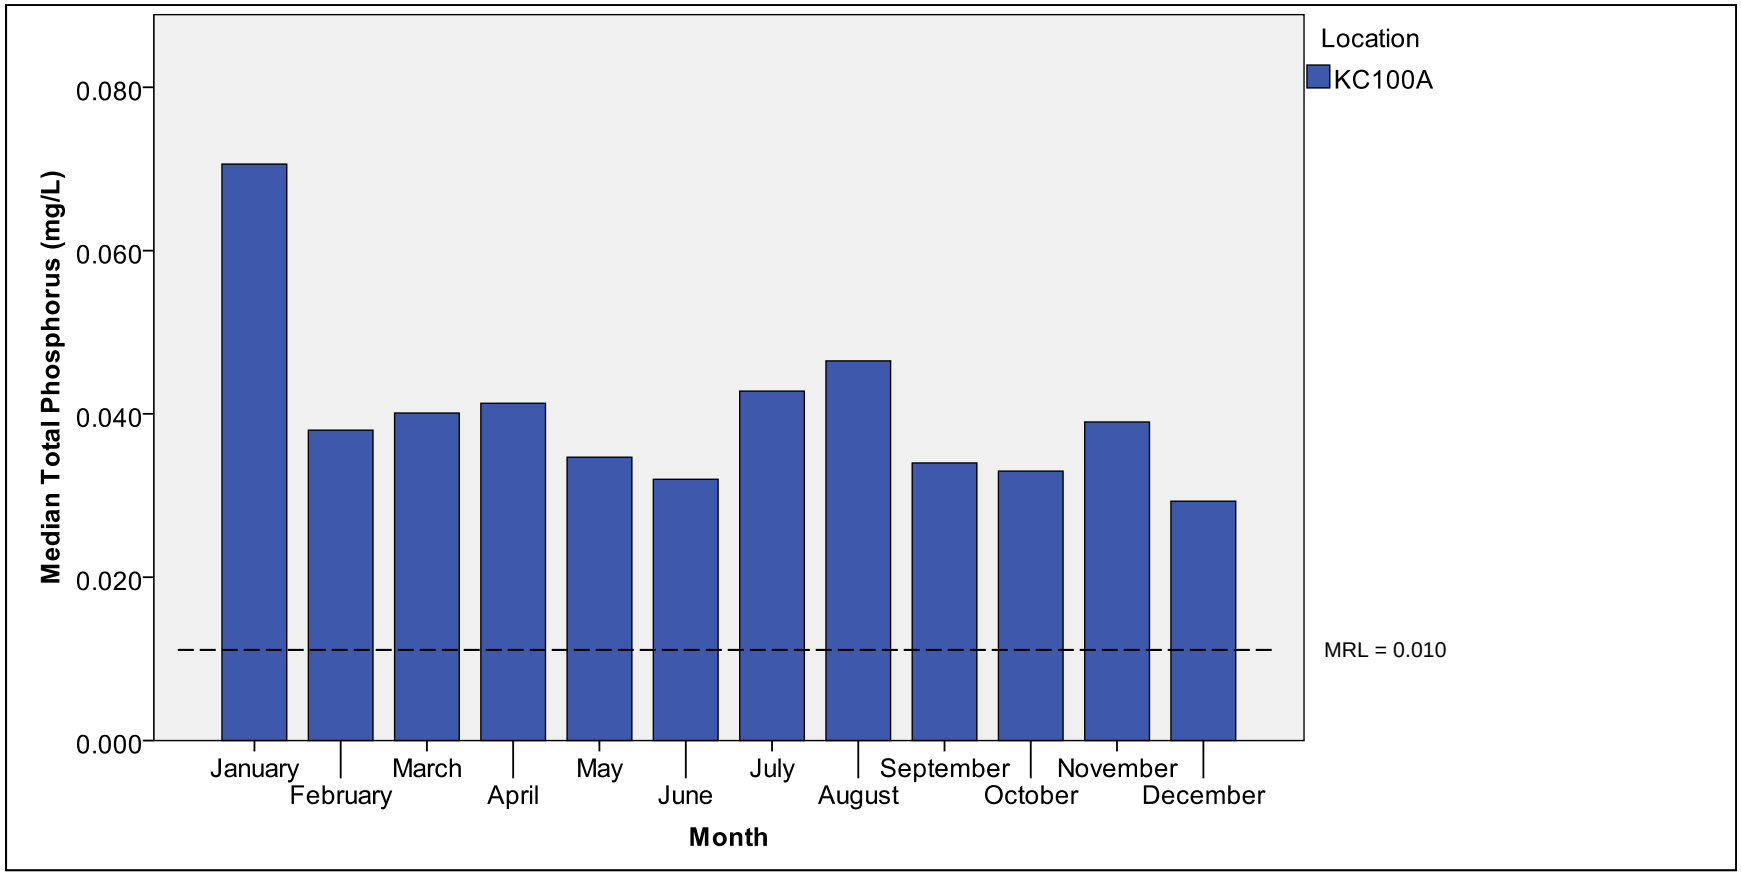

FIGURE 9.1-141
Total Phosphorus Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

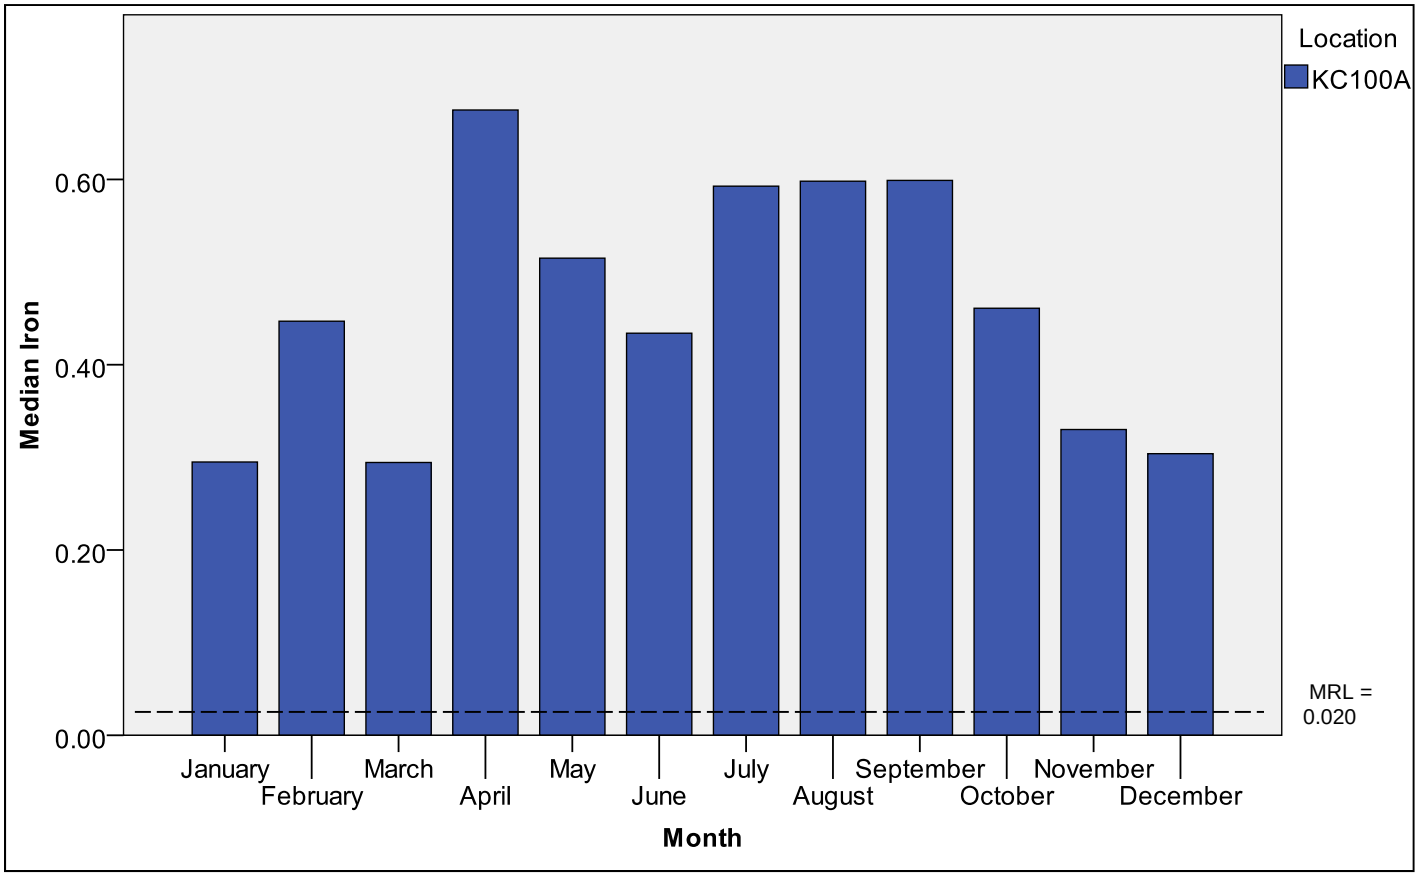

FIGURE 9.1-142
Iron Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

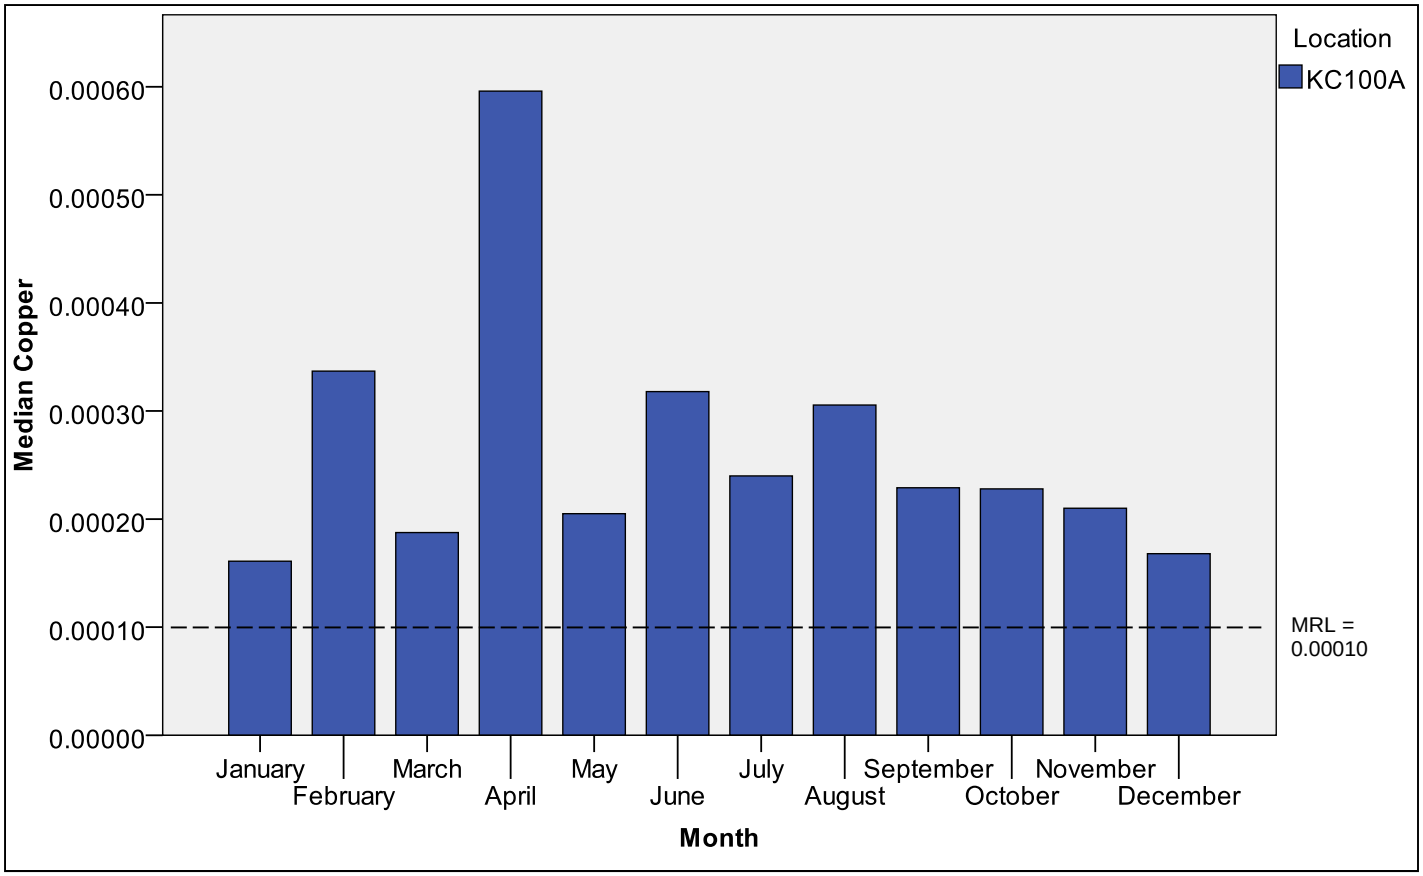

FIGURE 9.1-143
Copper Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

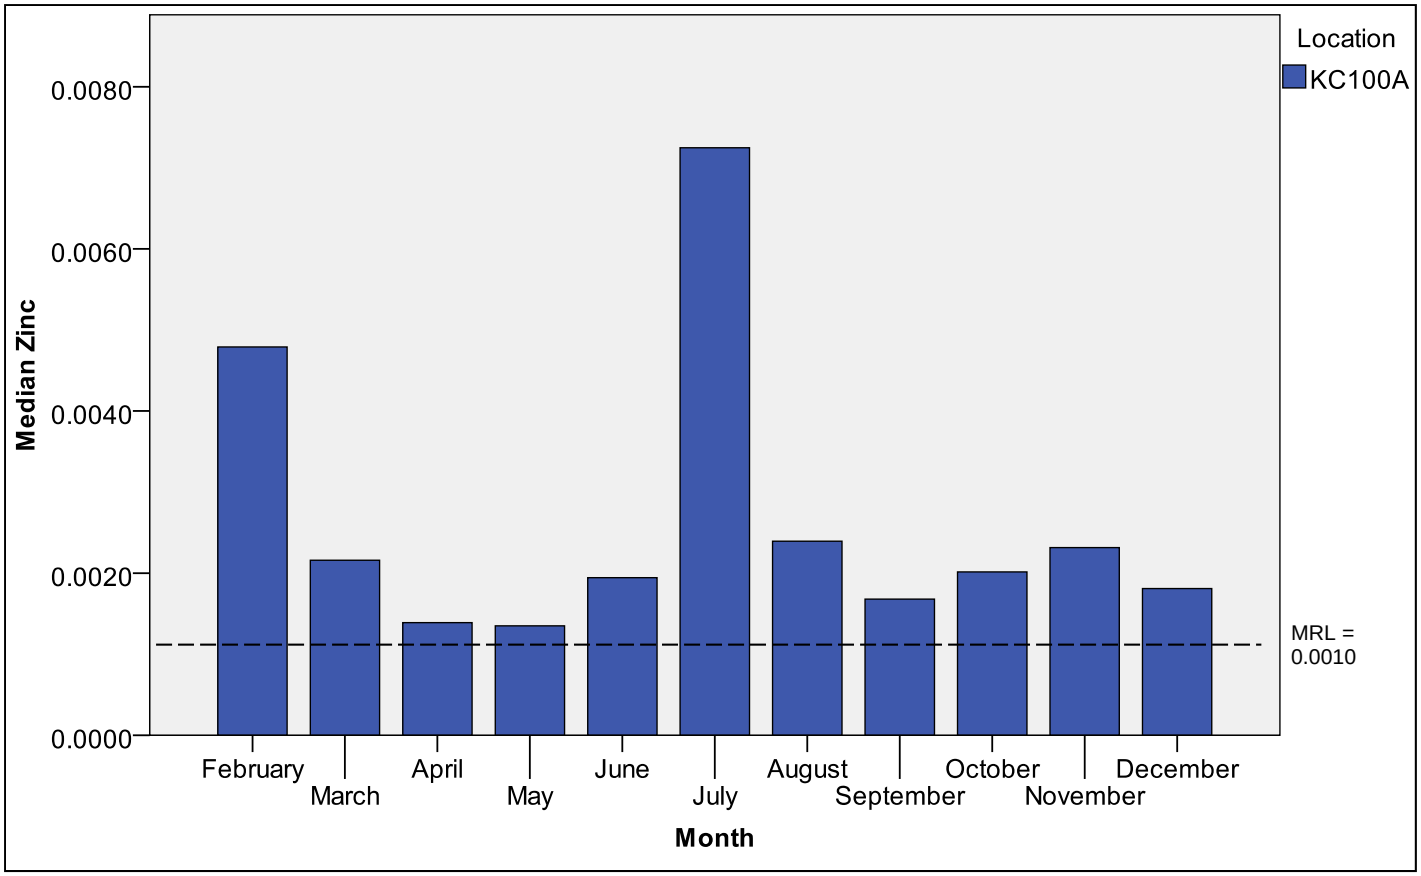

FIGURE 9.1-144
Zinc Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown. Zinc was not detected at location KC100A in January.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

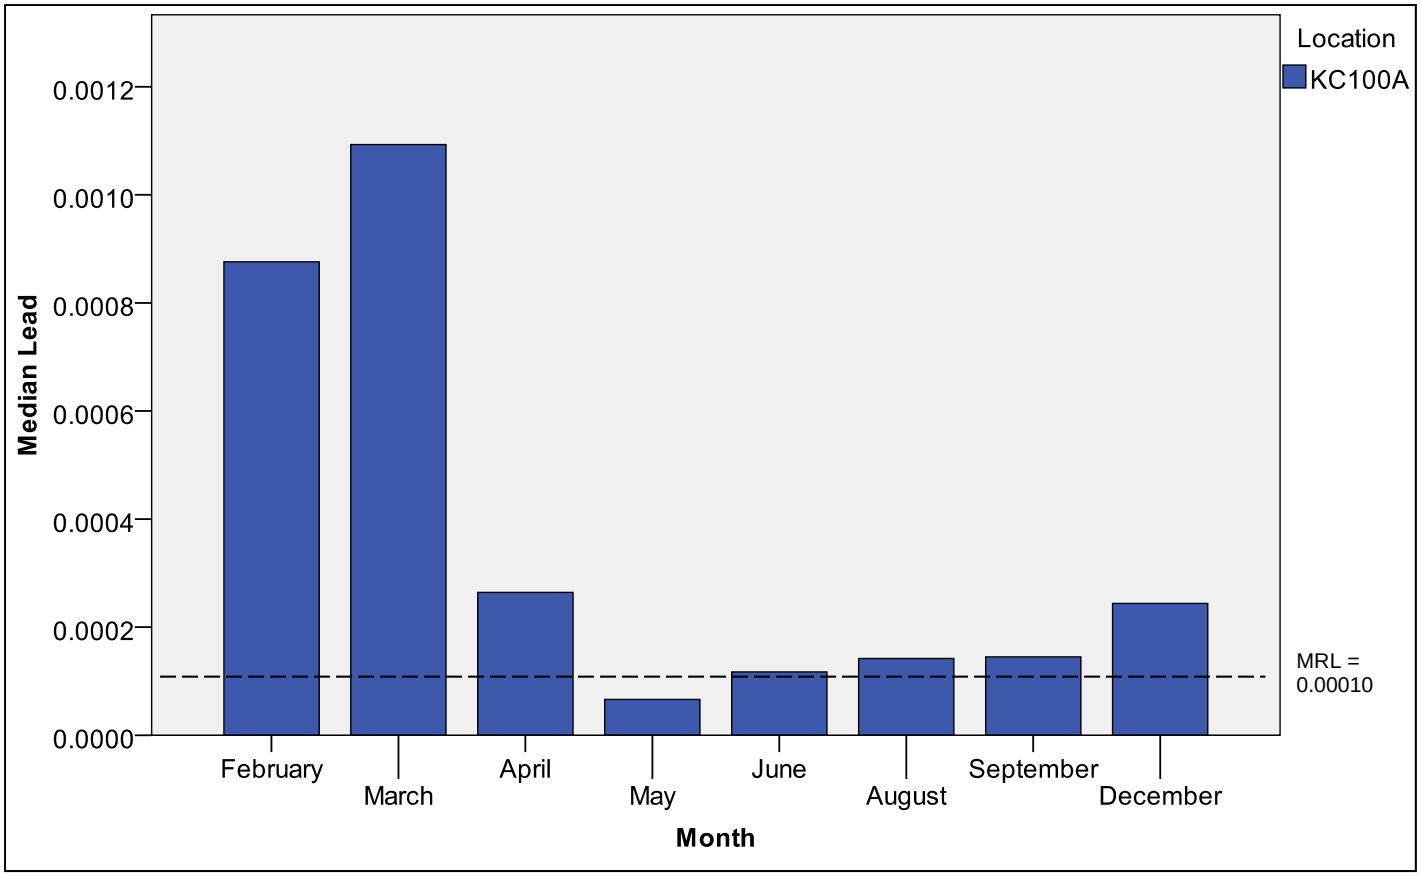

FIGURE 9.1-145
Lead Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each month.

Only detected values are shown. Lead was not detected at location KC100A in January, July, October, or November.

Analyte concentrations are in milligrams per liter (mg/L).

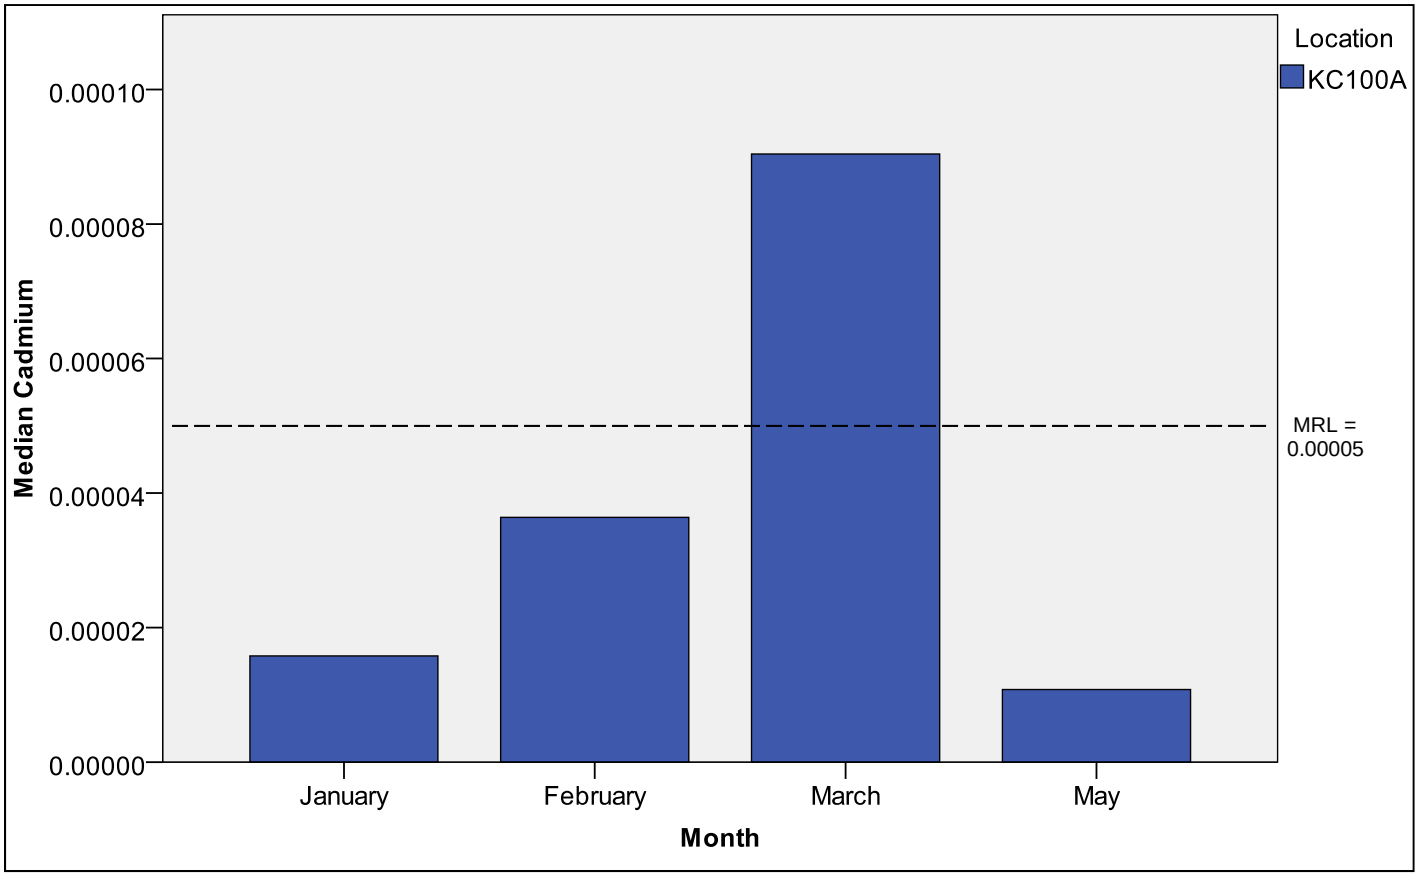

FIGURE 9.1-146
Cadmium Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown. Cadmium was not detected at location KC100A in April, June, July, August, September, October, November, or December.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

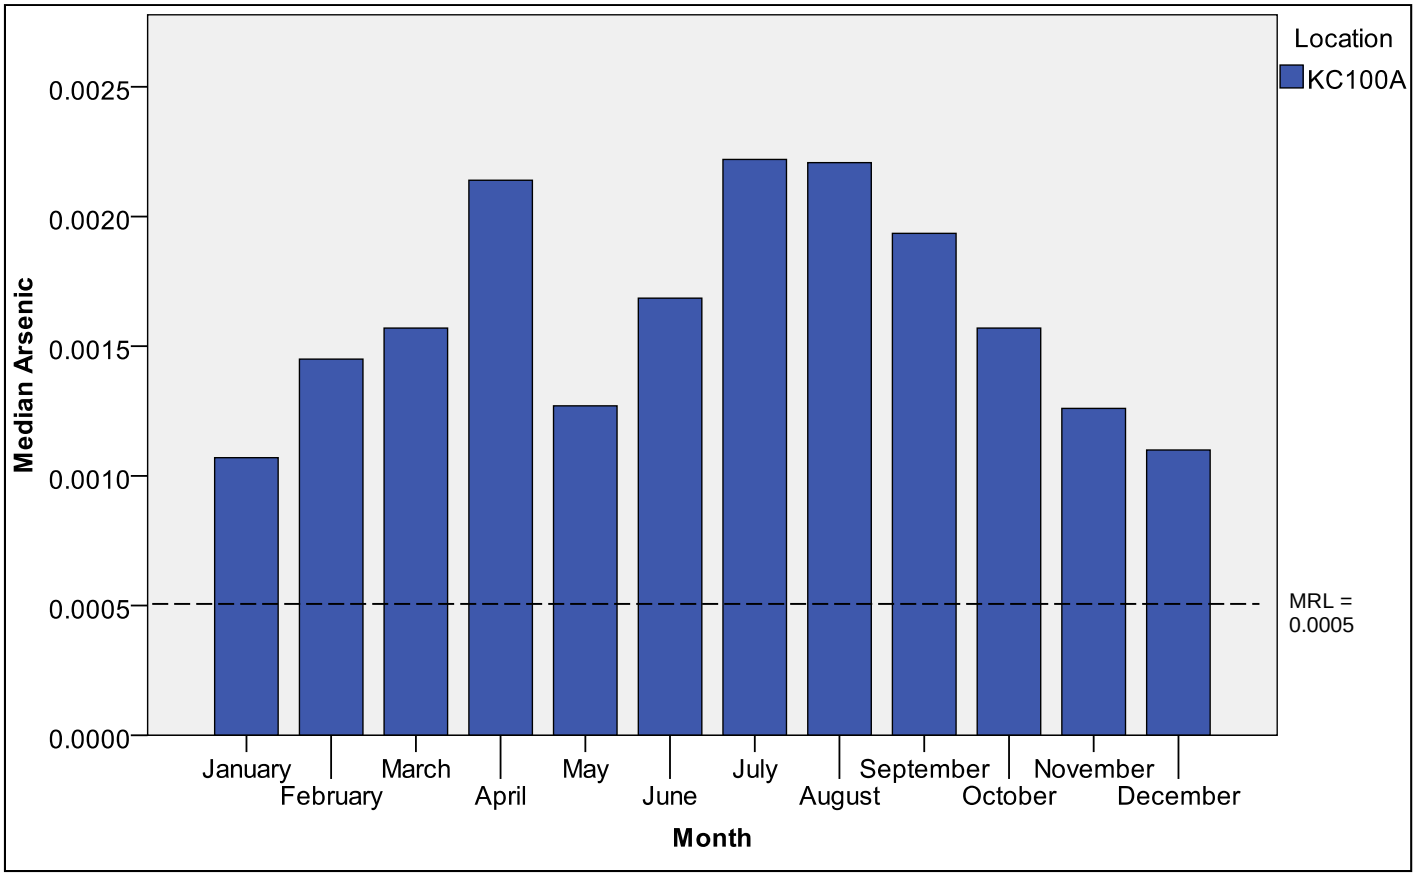

FIGURE 9.1-147
Arsenic Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

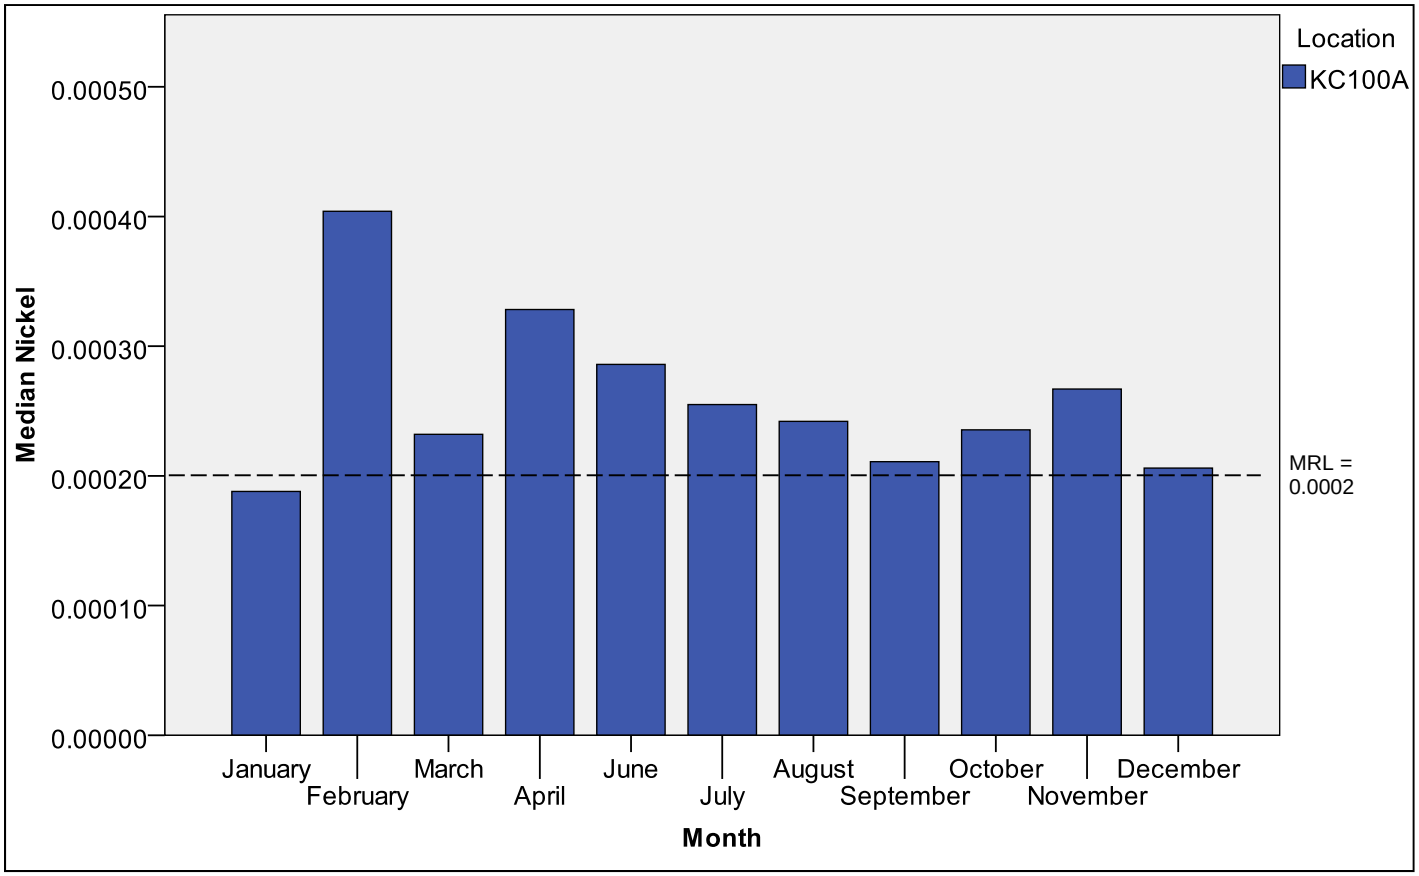

FIGURE 9.1-148
Nickel Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown. Nickel was not detected at location KC100A in May.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

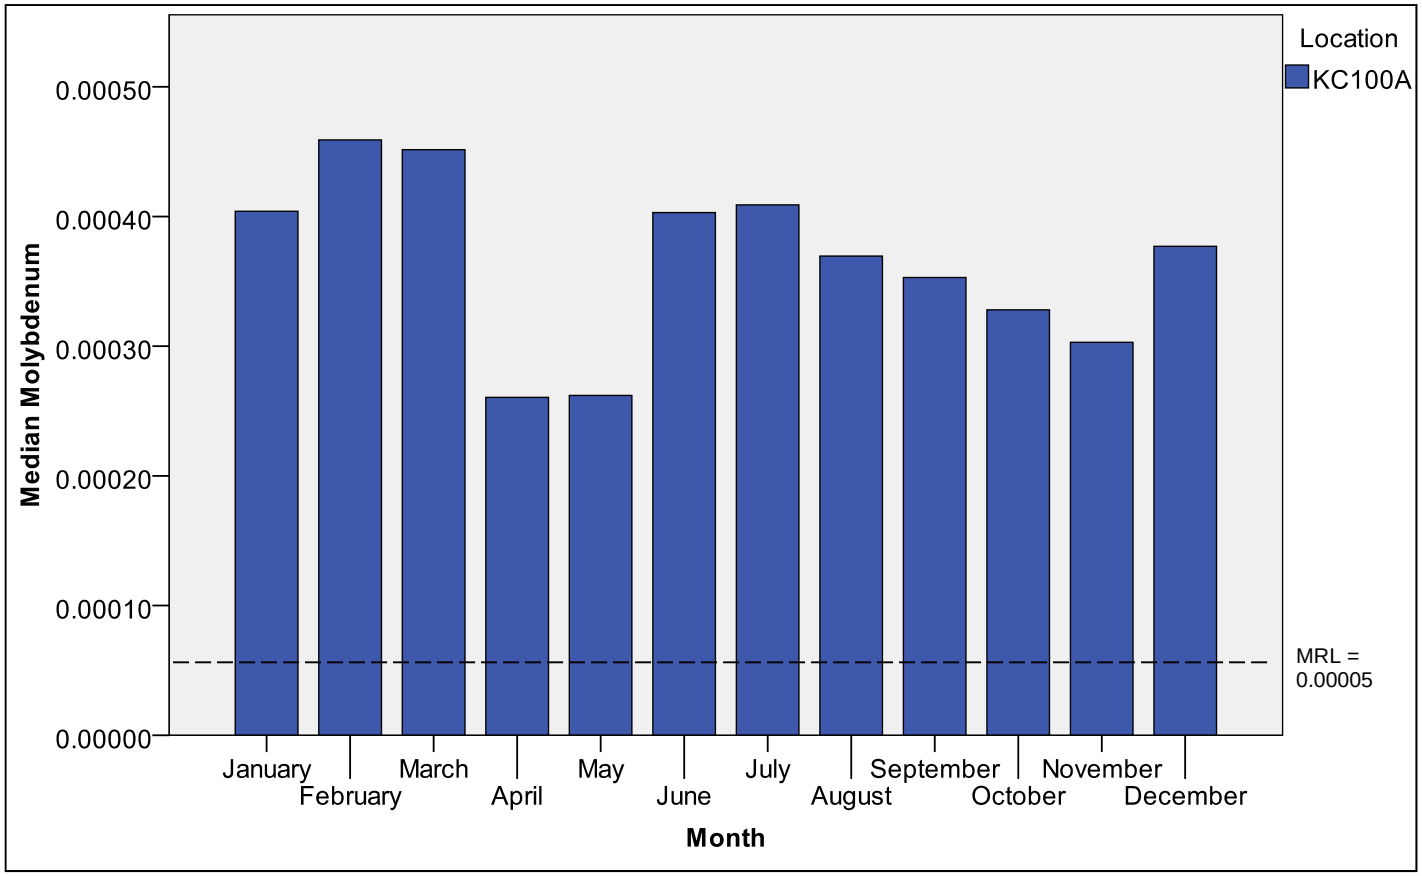

FIGURE 9.1-149
Molybdenum Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

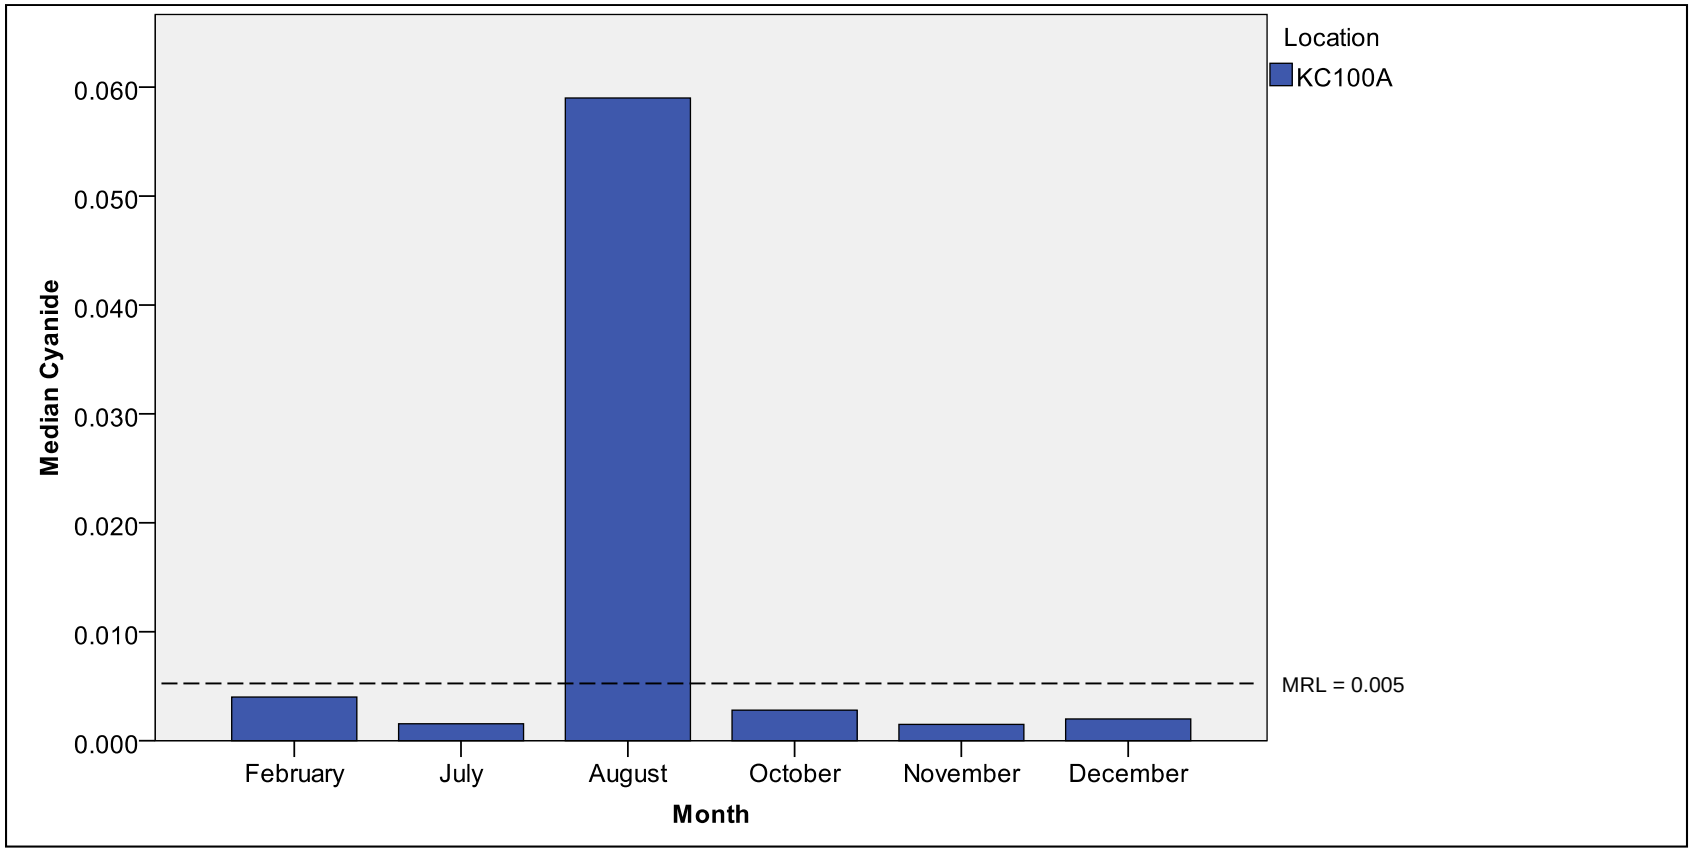

FIGURE 9.1-150
Total Cyanide Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:
Median concentrations are for all years (2004-2008) with available data for each month.
Only detected values are shown. Cyanide was not detected at location KC100A in January, March, April, May, June, or September.
Analyte concentrations are in milligrams per liter (mg/L).
MRL = method reporting limit.

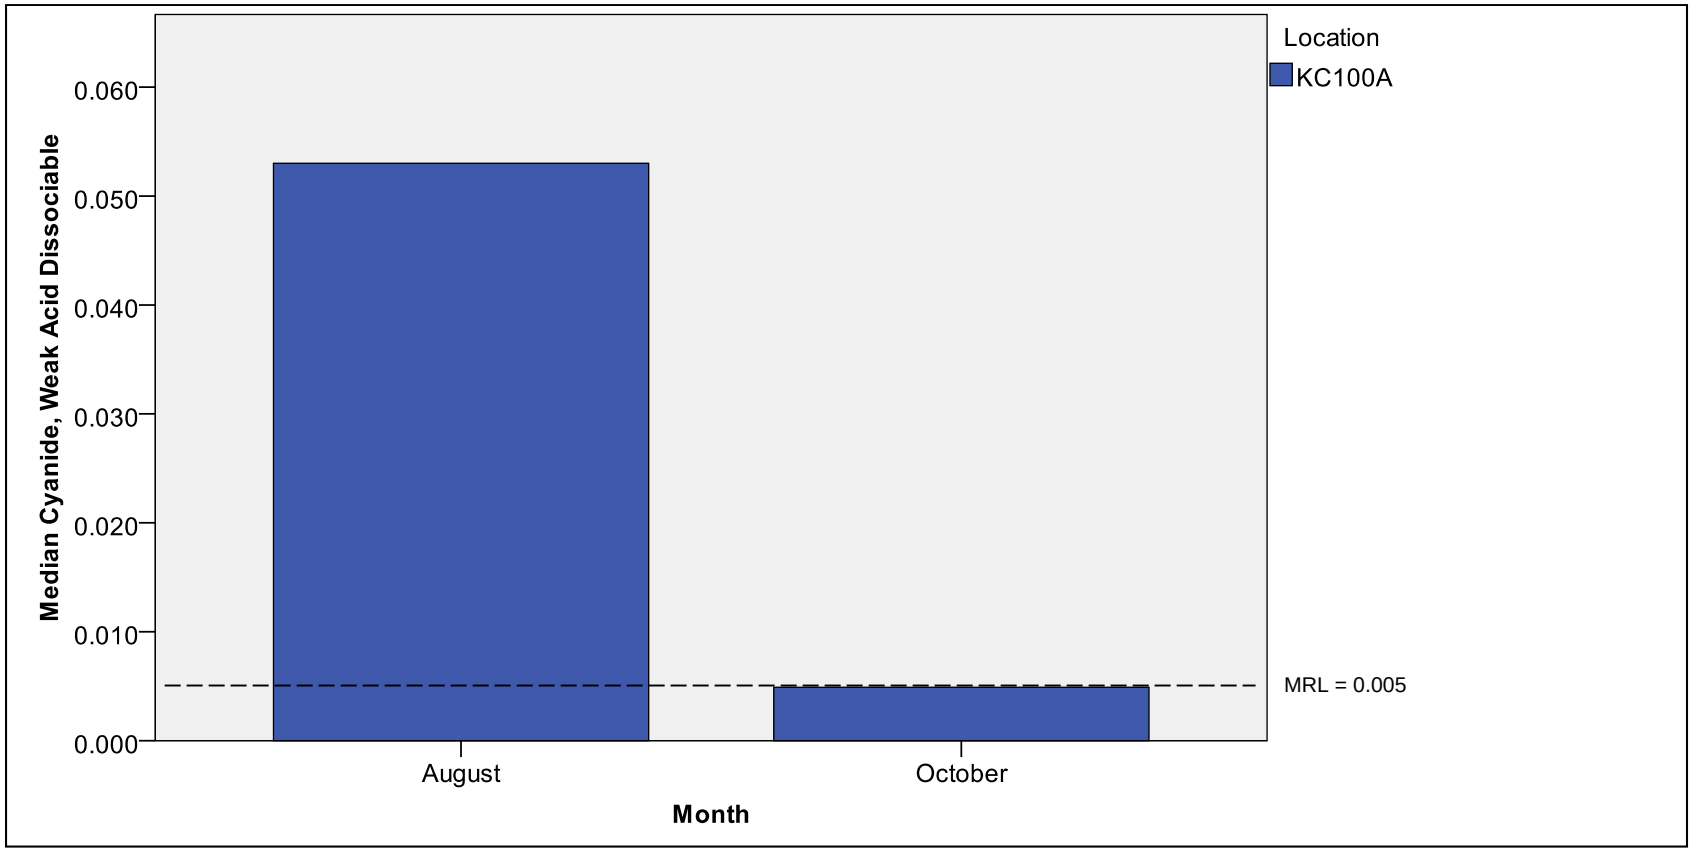

FIGURE 9.1-151
Cyanide, Weak Acid Dissociable (WAD) Surface Water Concentrations by Month, Kaskanak Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each month.

Only detected values are shown. Cyanide (Weak Acid Dissociable) was not detected at location KC100A in January, February, March, April, May, June, July, September, November, or December.

Analyte concentrations are in milligrams per liter (mg/L).

MRL = method reporting limit.

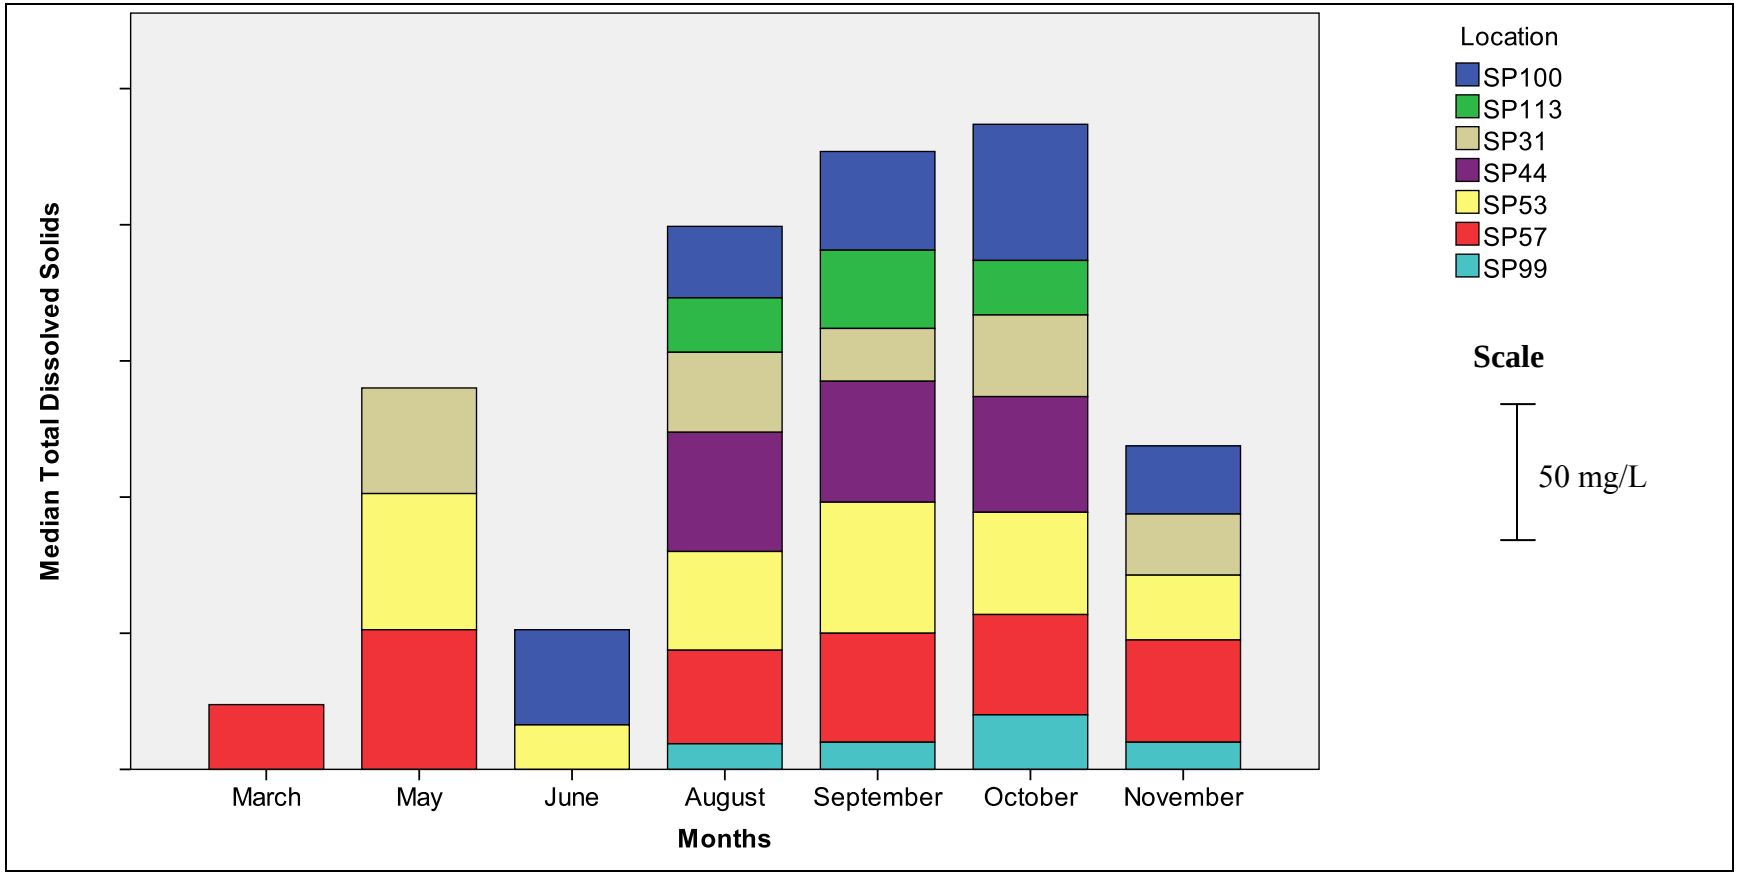

FIGURE 9.1-152
Total Dissolved Solids Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the North Fork Koktuli River Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 10 mg/L.

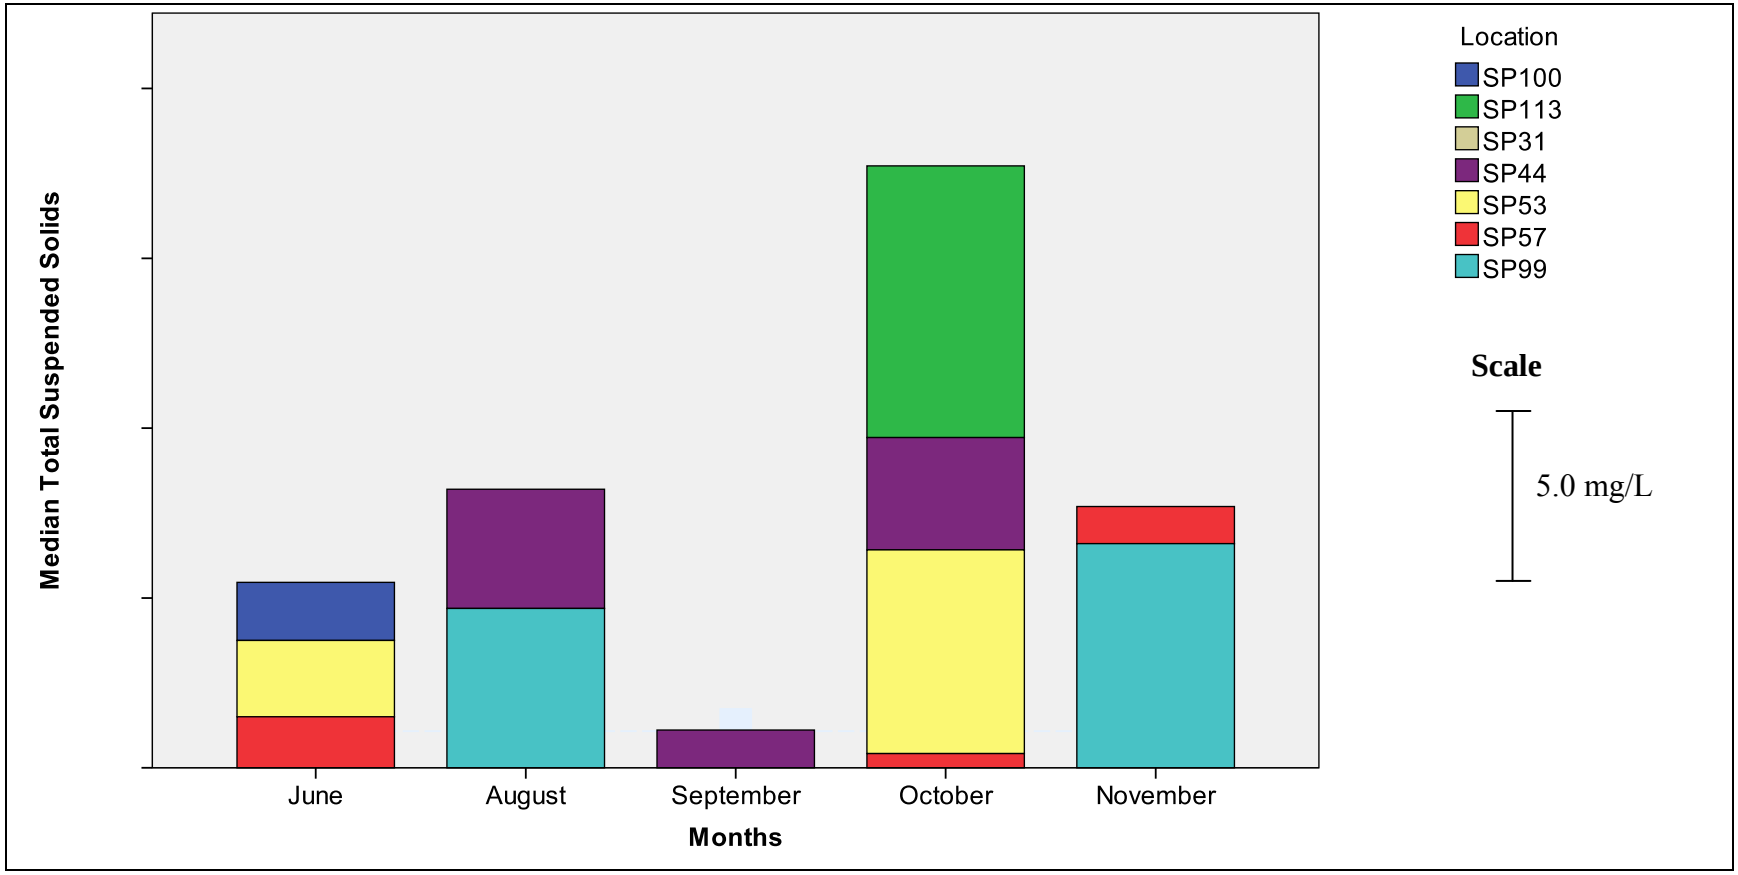

FIGURE 9.1-153
Total Suspended Solids Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the North Fork Koktuli River Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 1.08 mg/L.

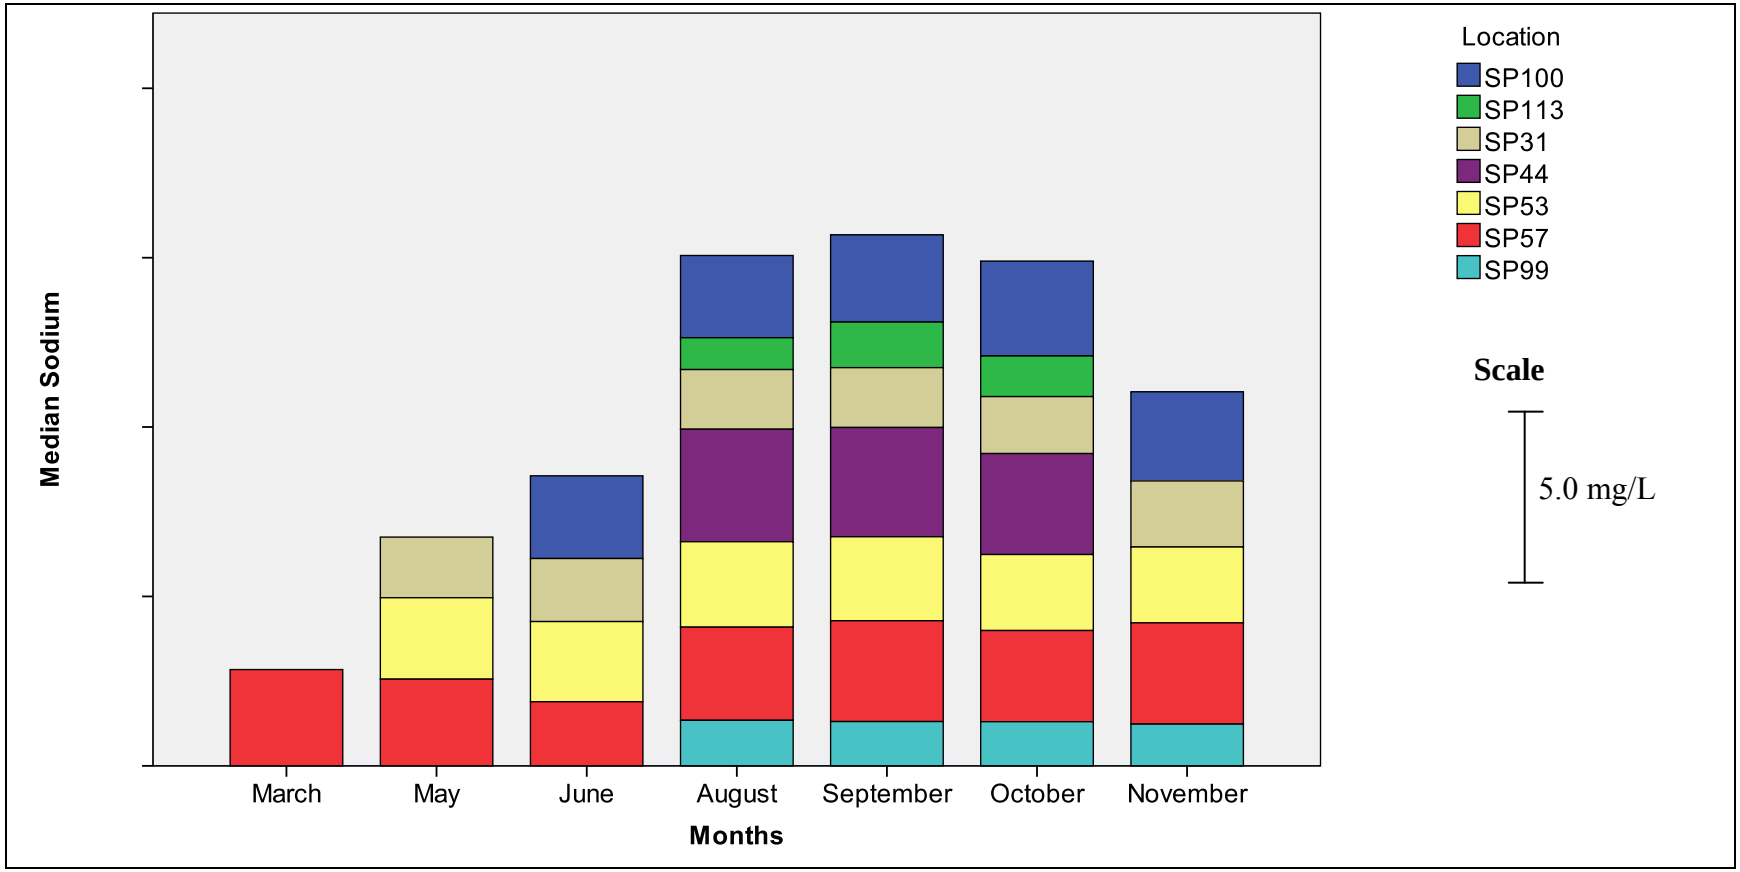

FIGURE 9.1-154

Hardness as $CaCO_3$ Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 1.0 mg/L.

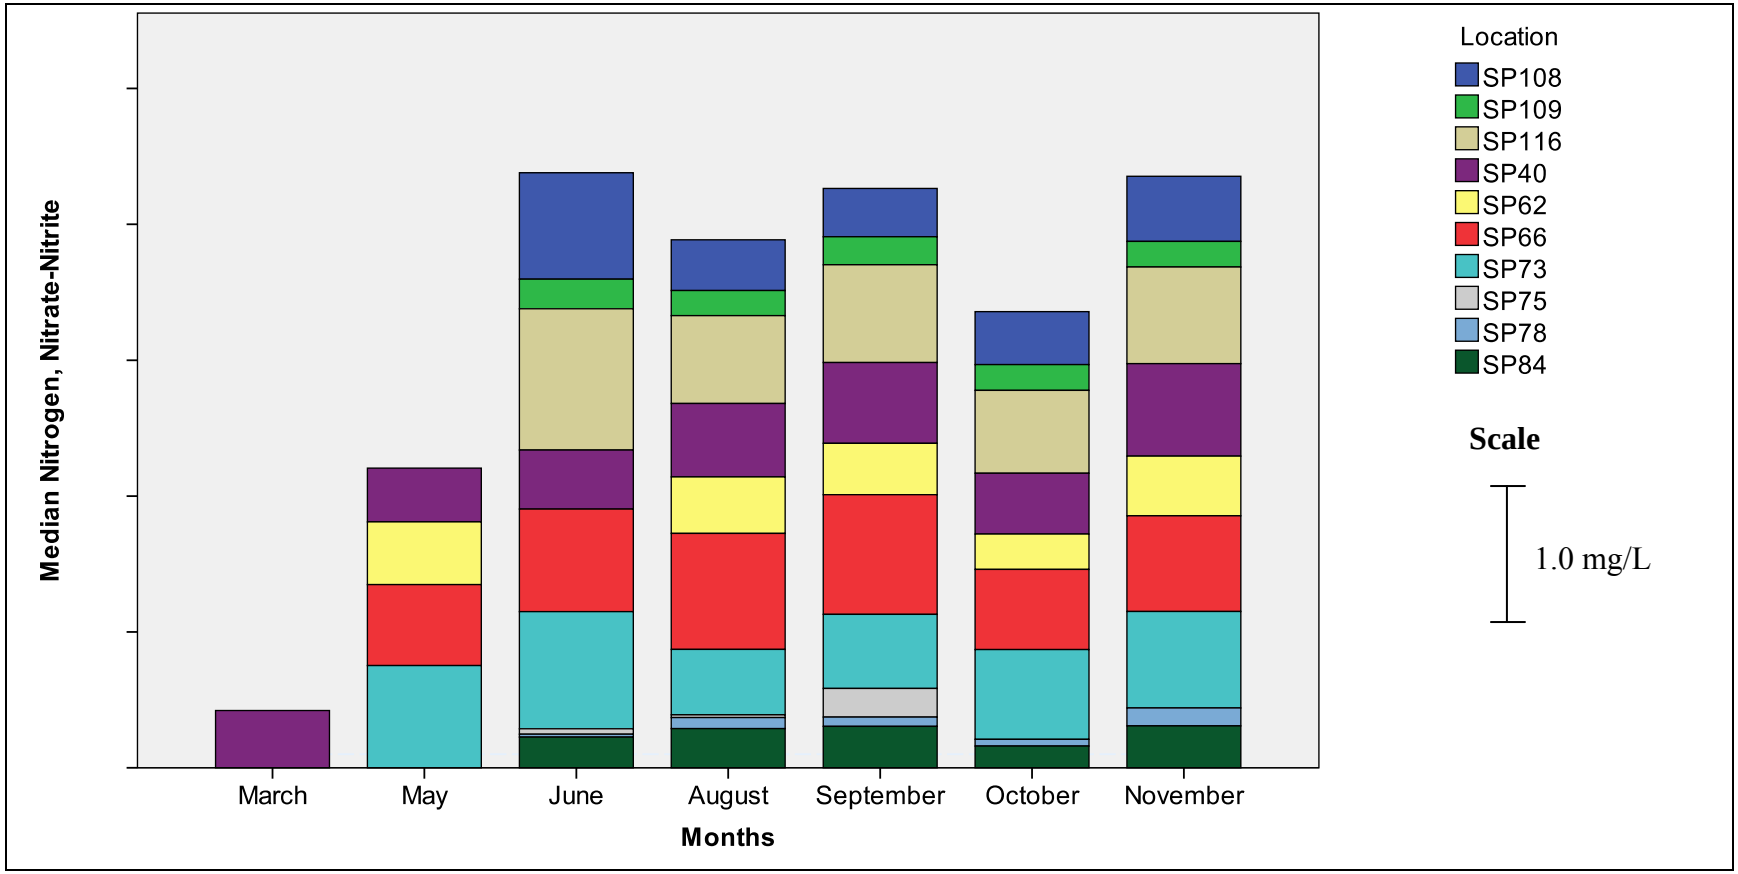

FIGURE 9.1-195
Total Nitrate+Nitrite (as N) Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.10 mg/L.

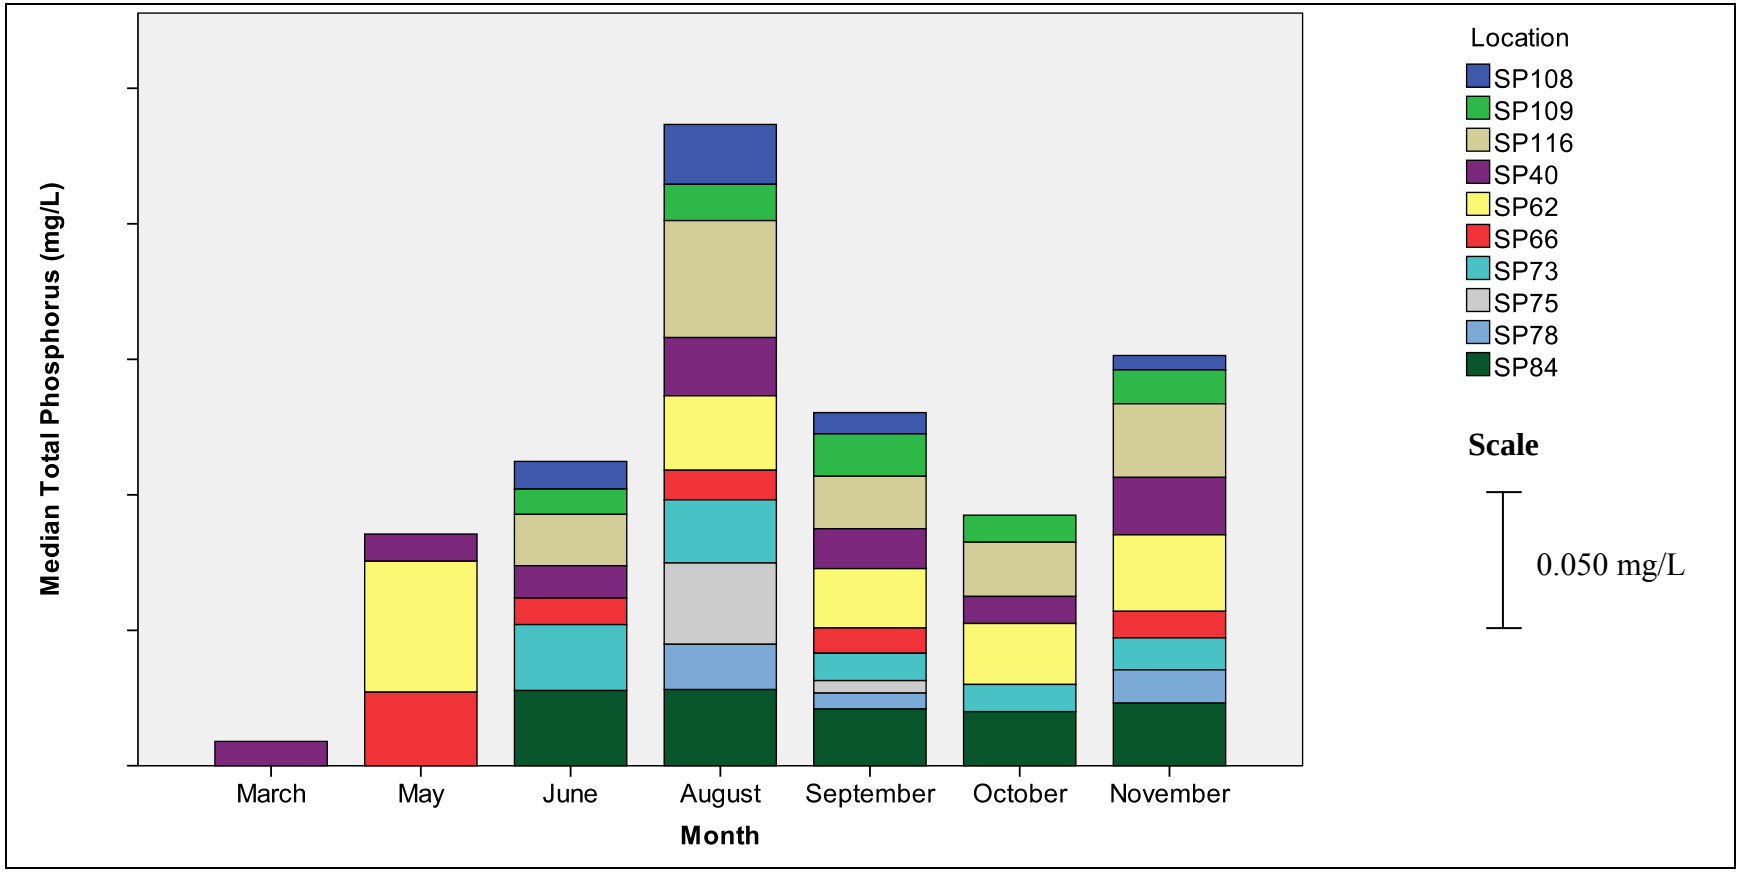

FIGURE 9.1-196
Total Phosphorus Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.010 mg/L.

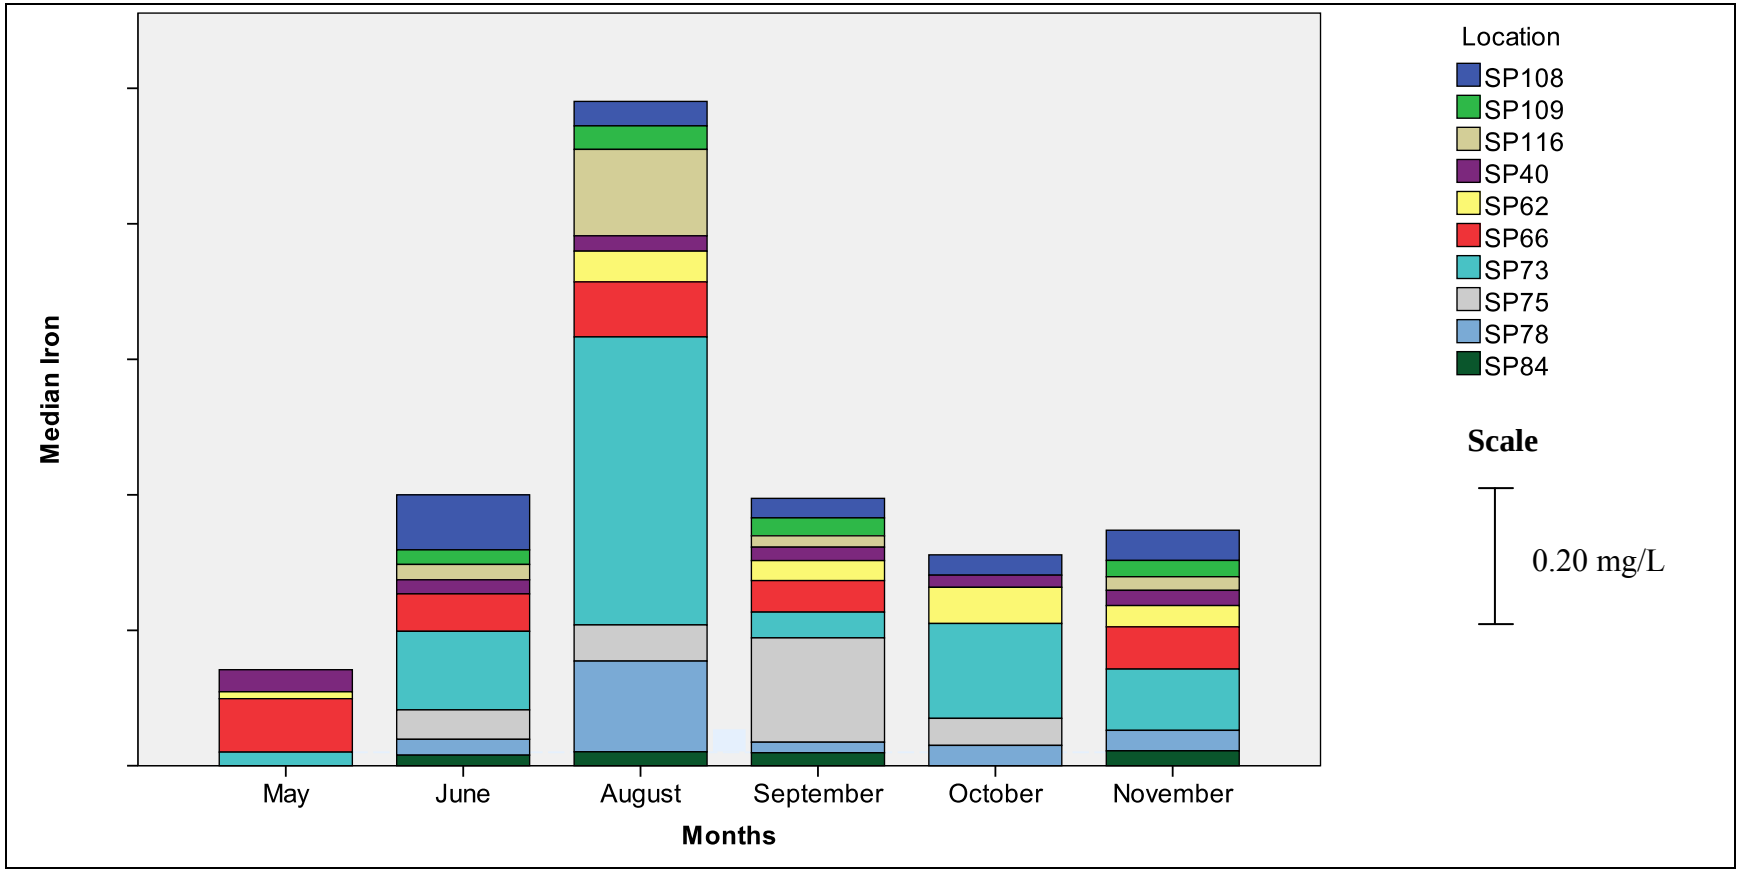

FIGURE 9.1-197
Iron Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.020 mg/L.

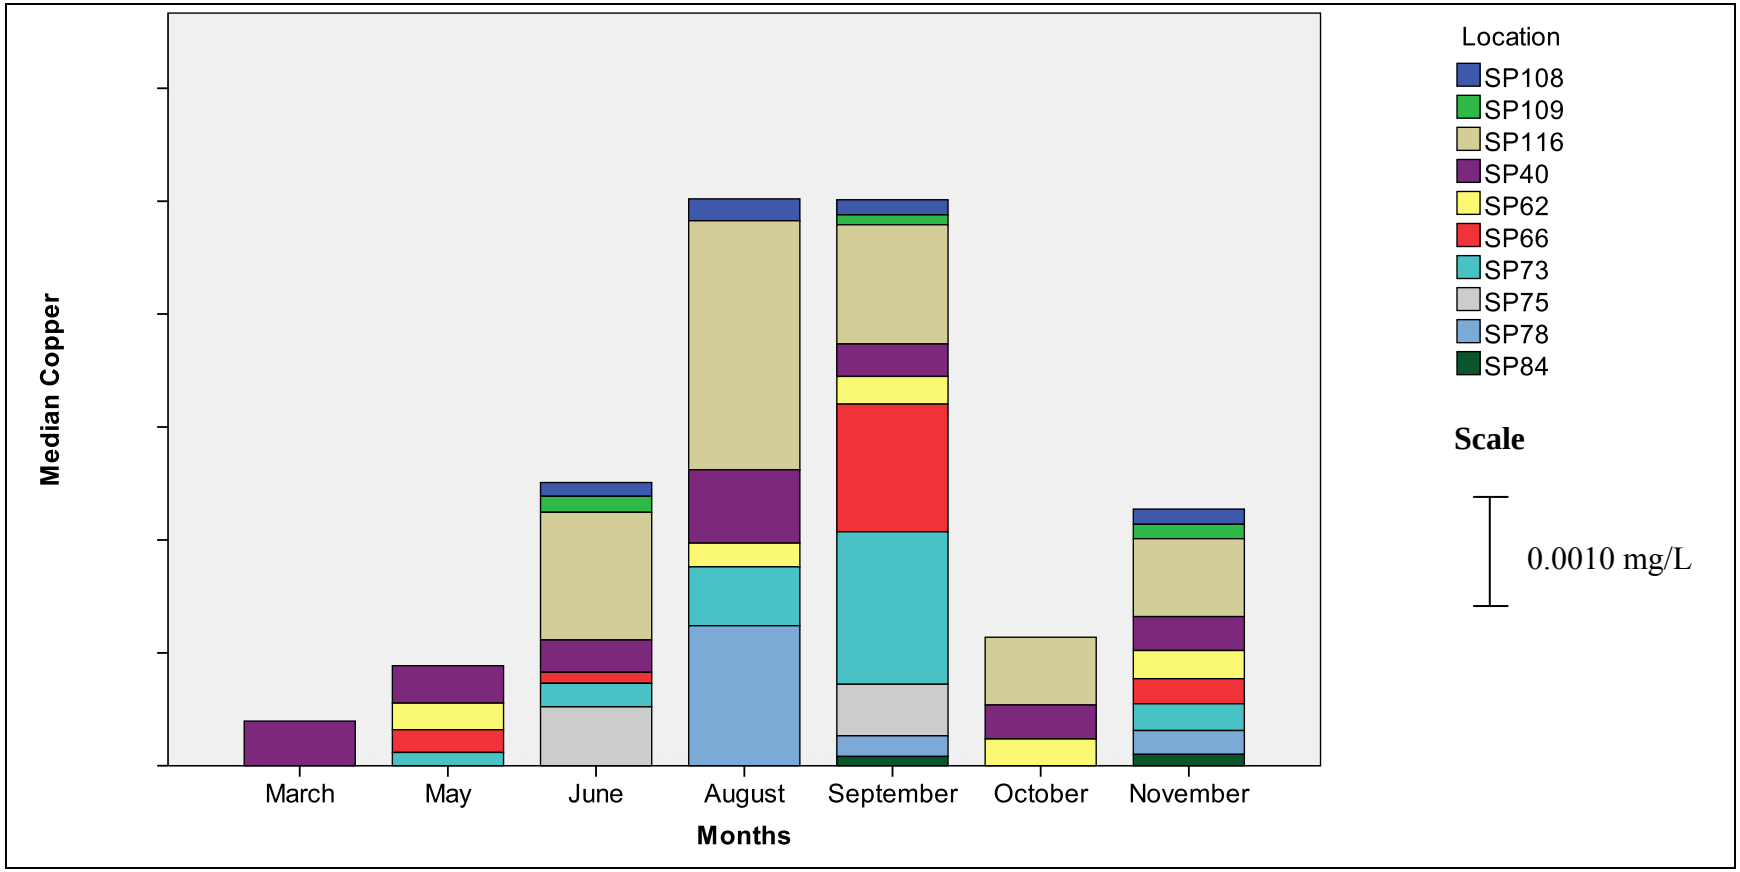

FIGURE 9.1-198
Copper Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.00010 mg/L.

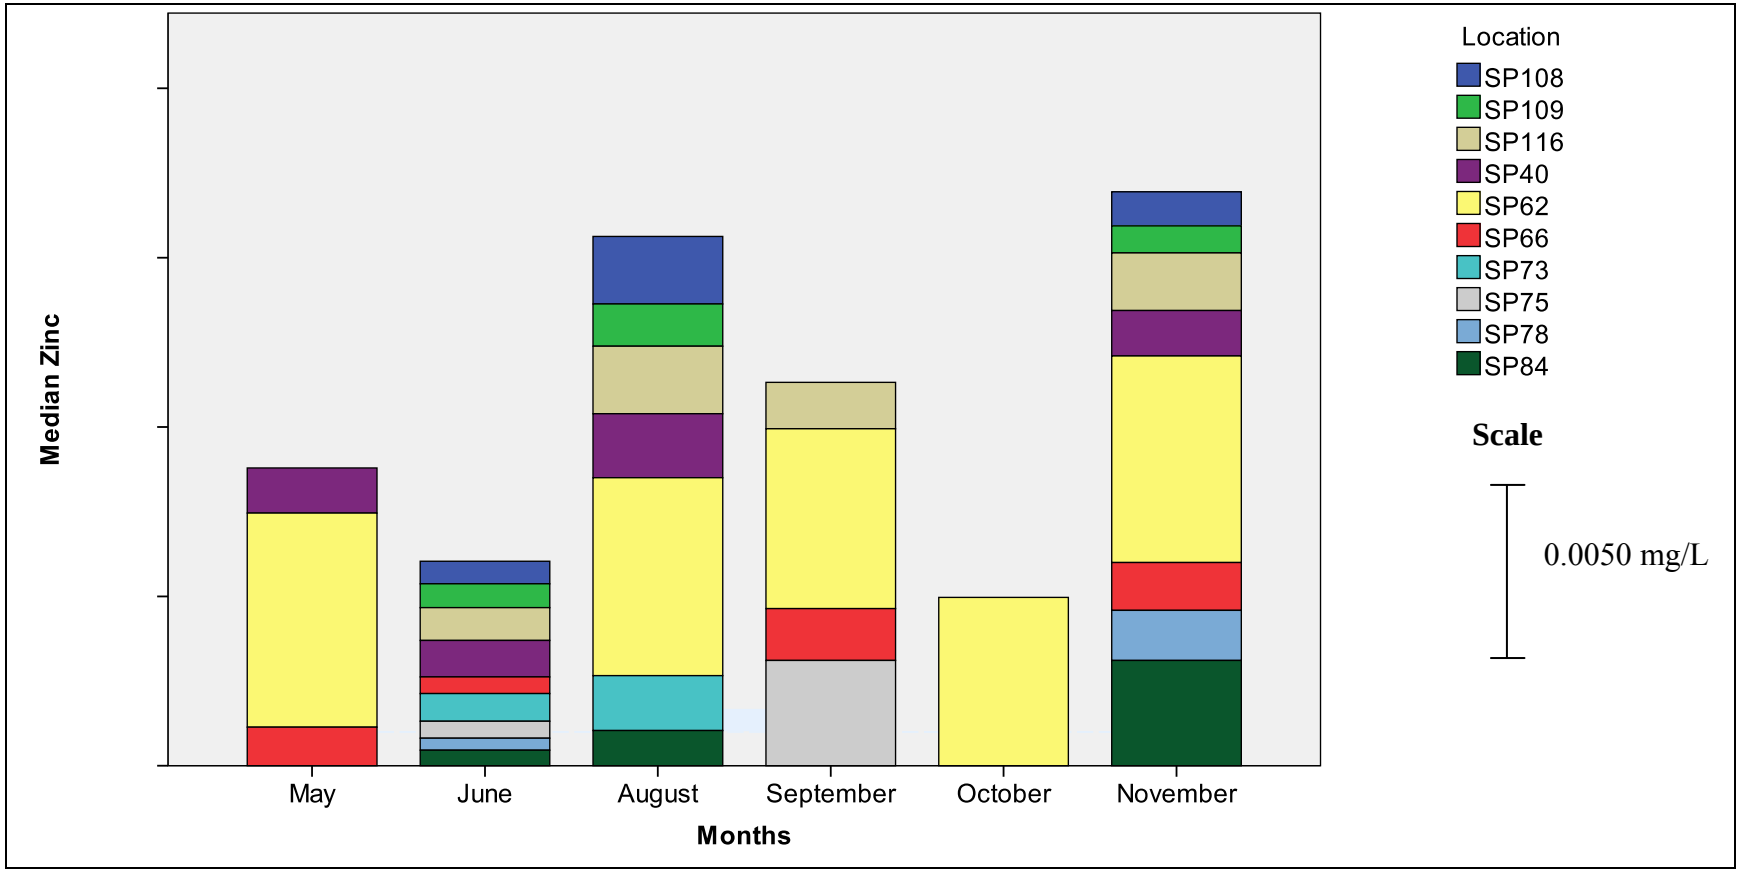

FIGURE 9.1-199
Zinc Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.0010 mg/L.

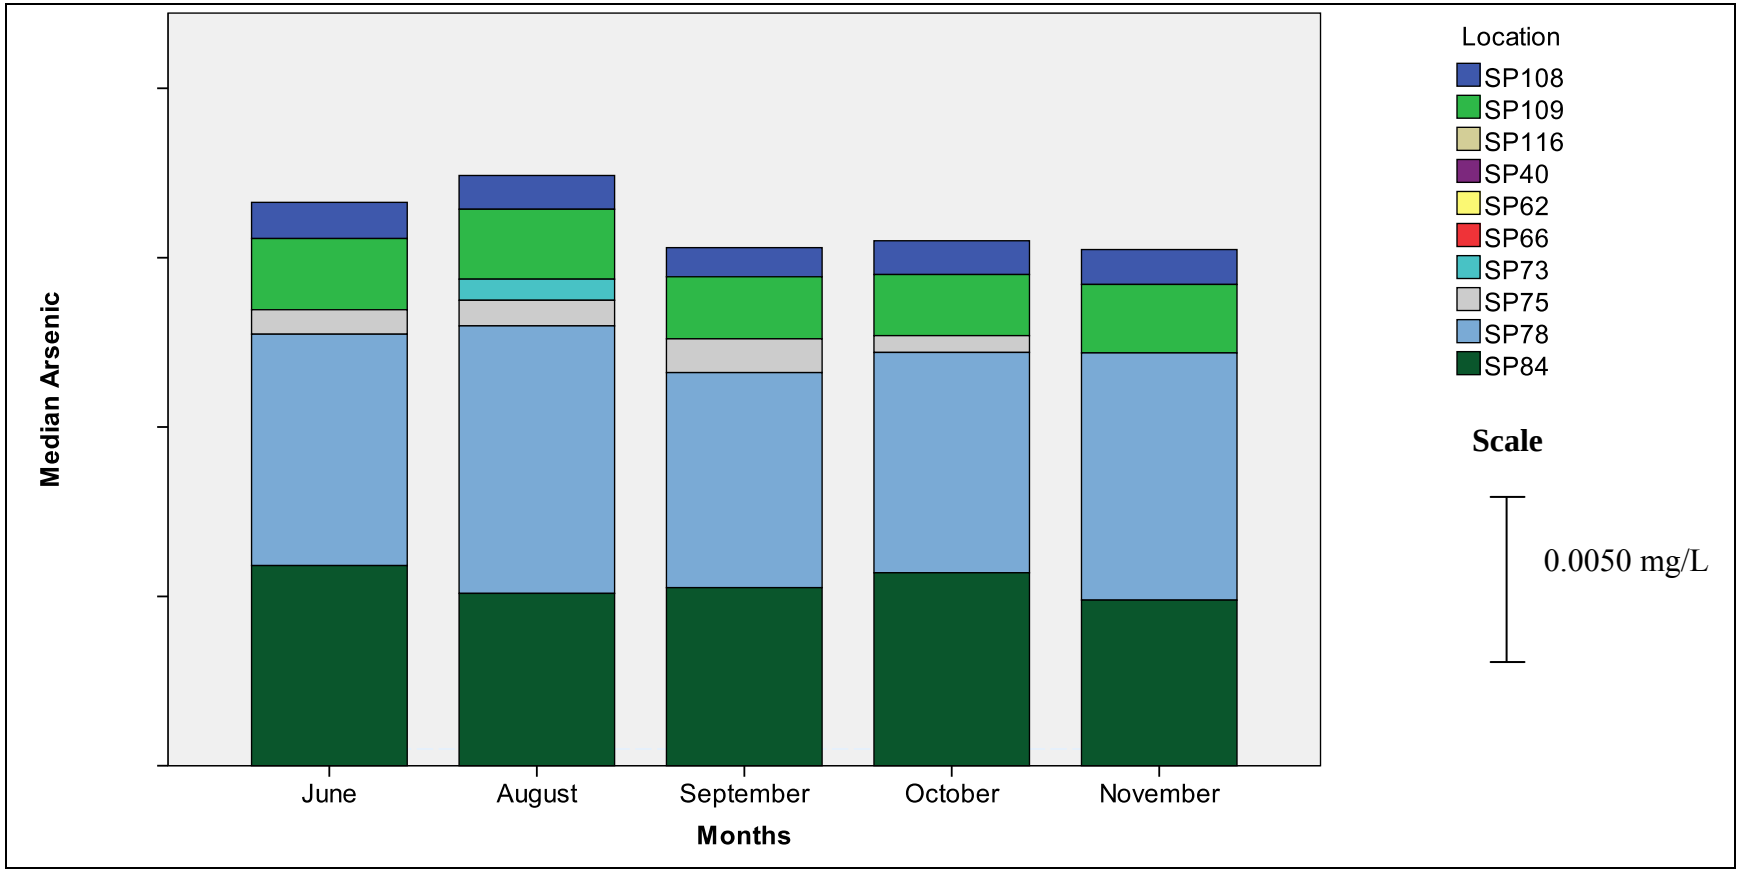

FIGURE 9.1-200
Arsenic Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.00050 mg/L.

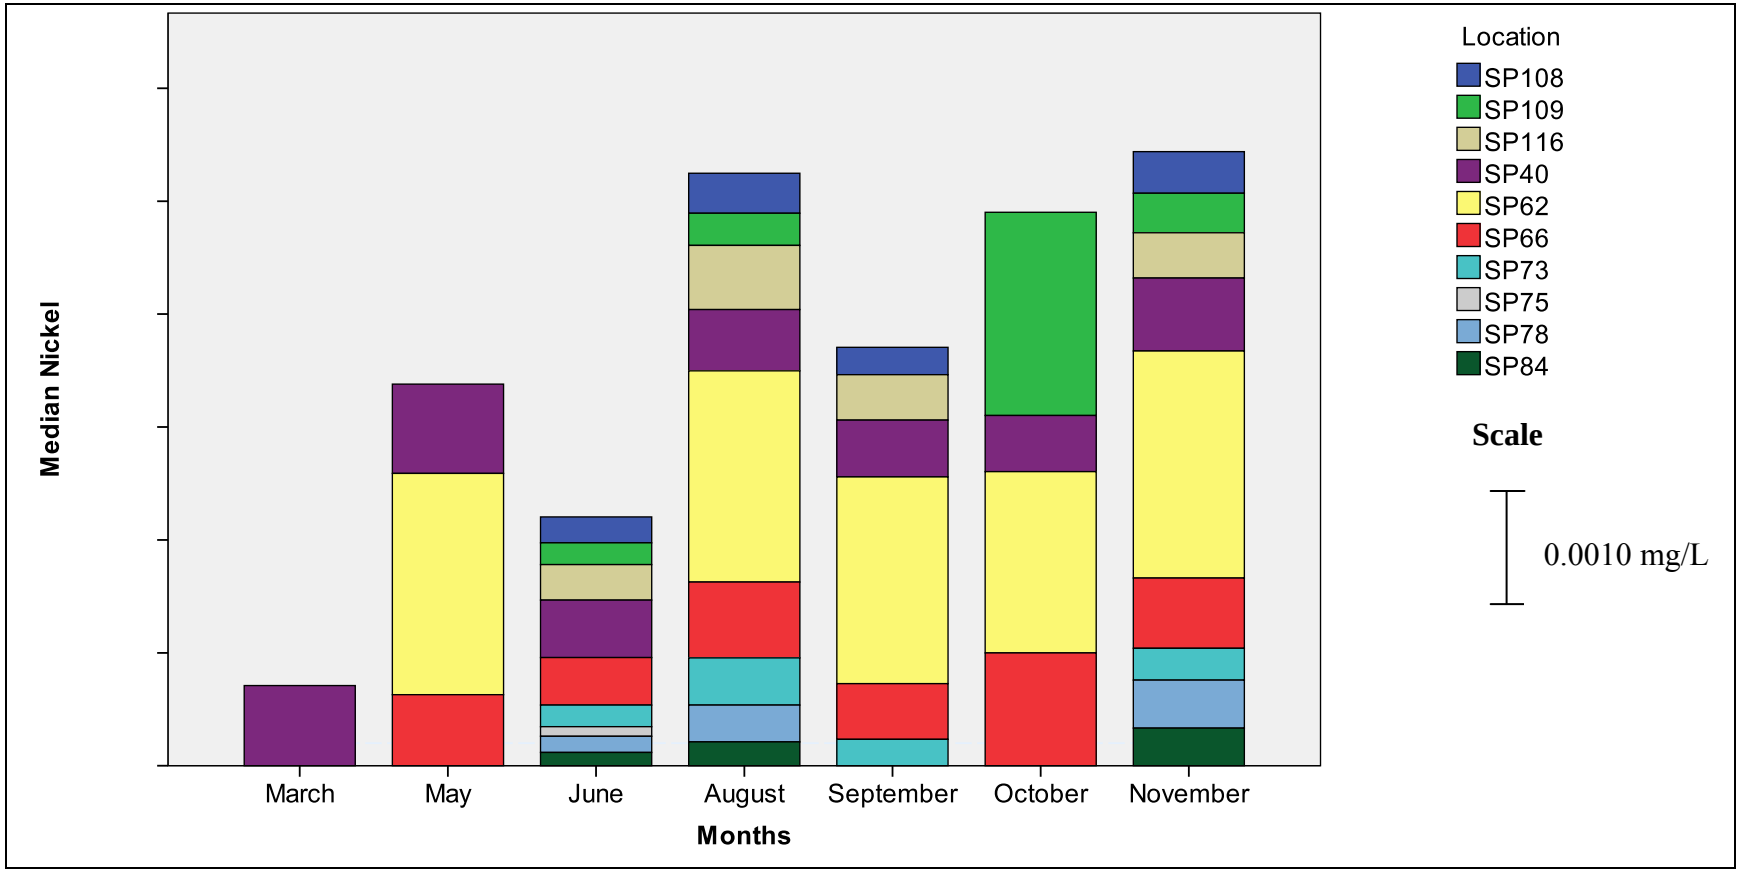

FIGURE 9.1-201
Nickel Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.00020 mg/L.

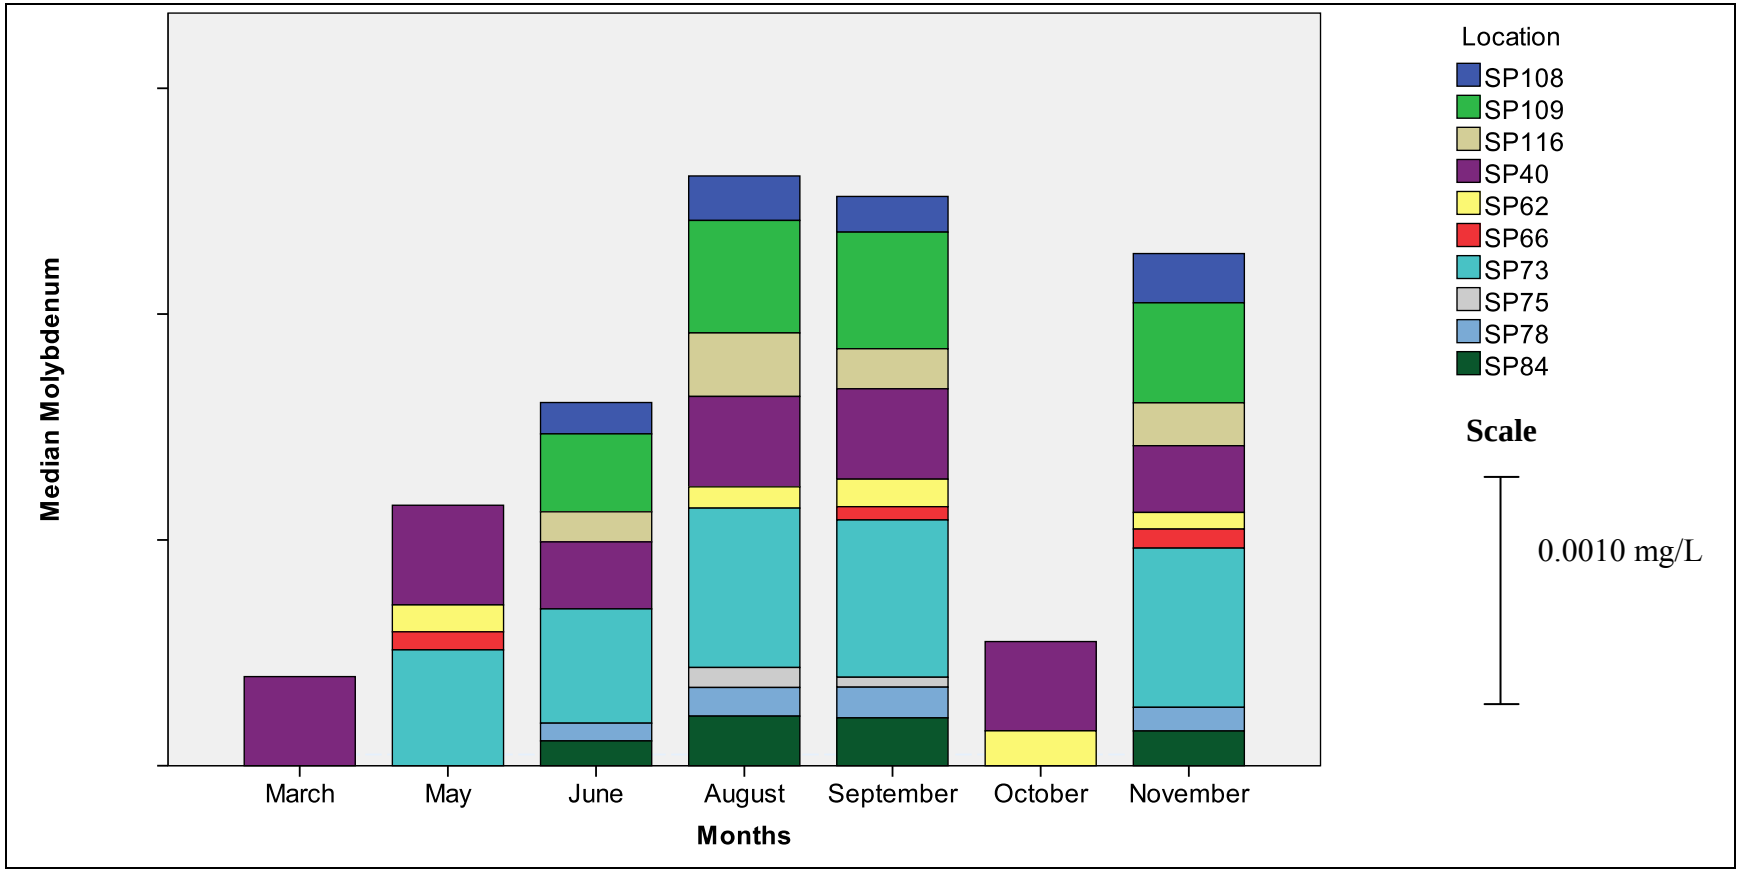

FIGURE 9.1-202
Molybdenum Seep Water Samples: Comparative Distribution of Mean Concentrations by Location and Month, Seeps in the Upper Talarik Creek Drainage

Notes:

Stacked graphs do not indicate cumulative or additive concentrations for the overall drainage, they are solely meant to display the variable concentrations amongst stations in relation to their location in the drainage.

Median concentrations are for all years (2004-2008) with available data for each month and sample location.

Only detected values are shown. Analyte concentrations are in milligrams per liter (mg/L). Method reporting limit (MRL) = 0.000050 mg/L.

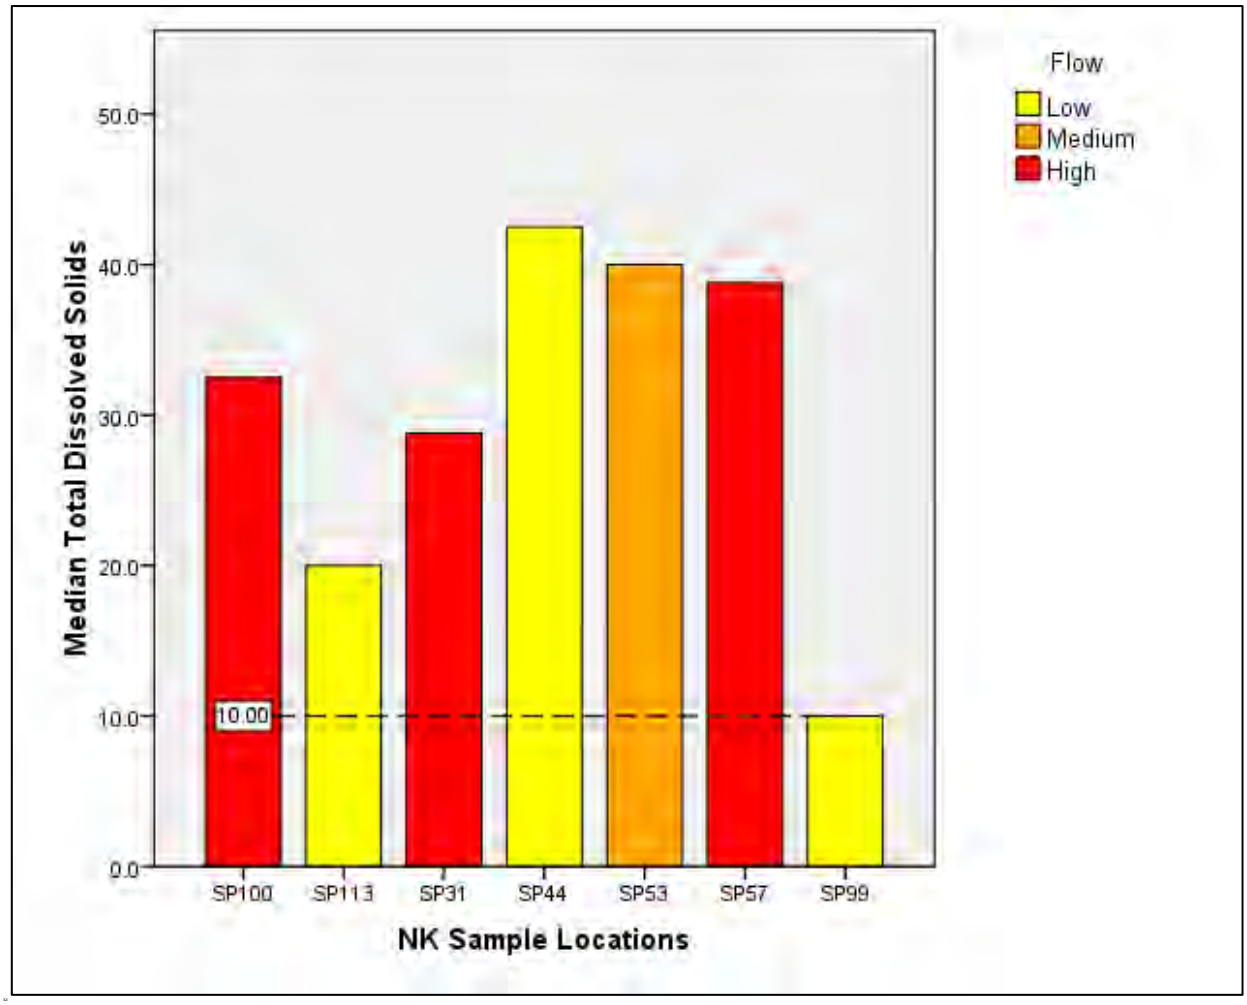

FIGURE 9.1-203
Total Dissolved Solids Concentrations and Flow Velocity in Seeps by Location, North Fork Koktuli River Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

NK = North Fork Koktuli.

UT = Upper Talarik Creek.

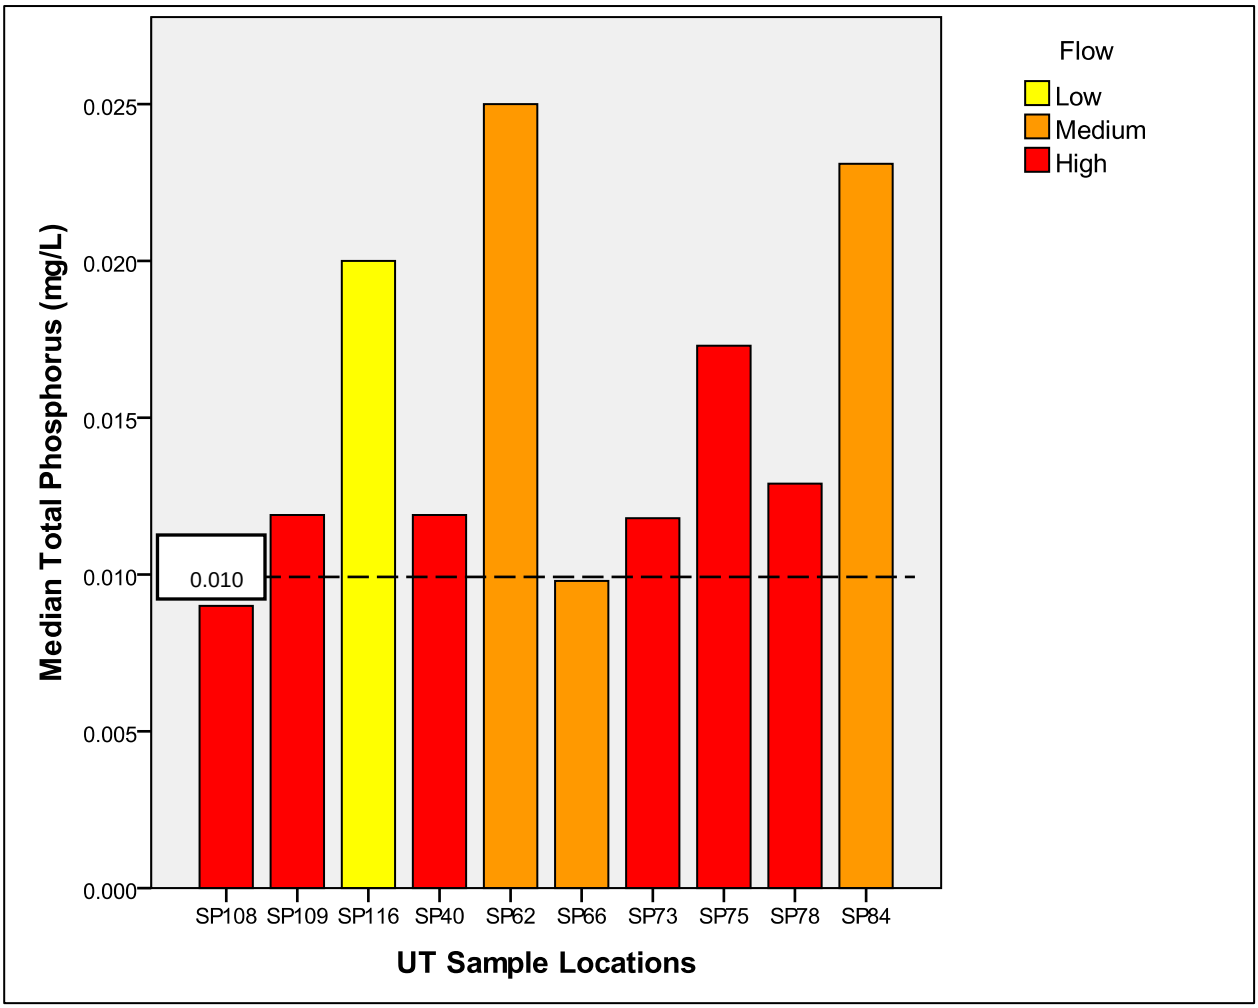

FIGURE 9.1-240
Total Phosphorus Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

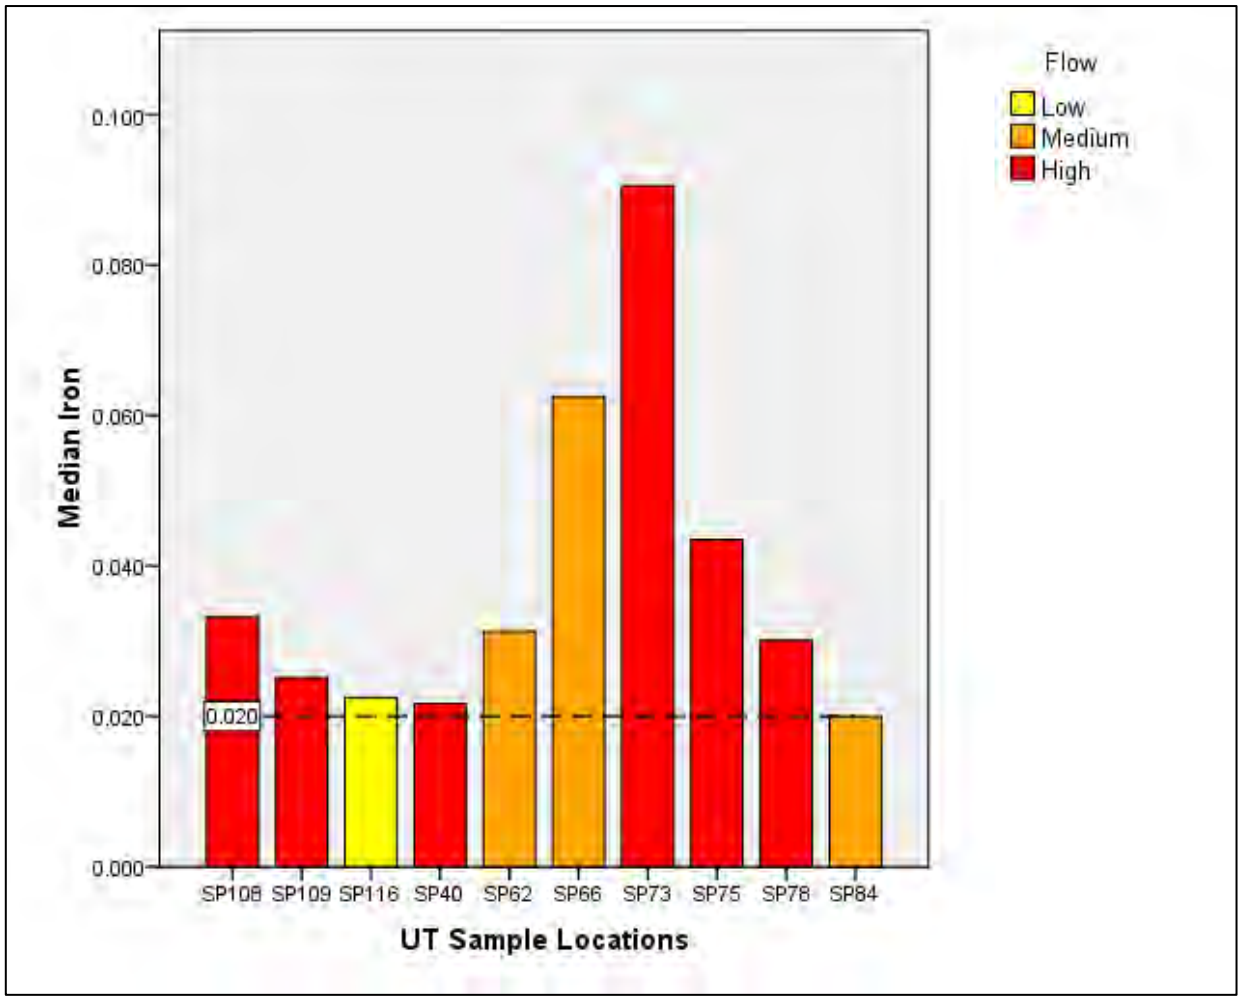

FIGURE 9.1-241
Iron Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

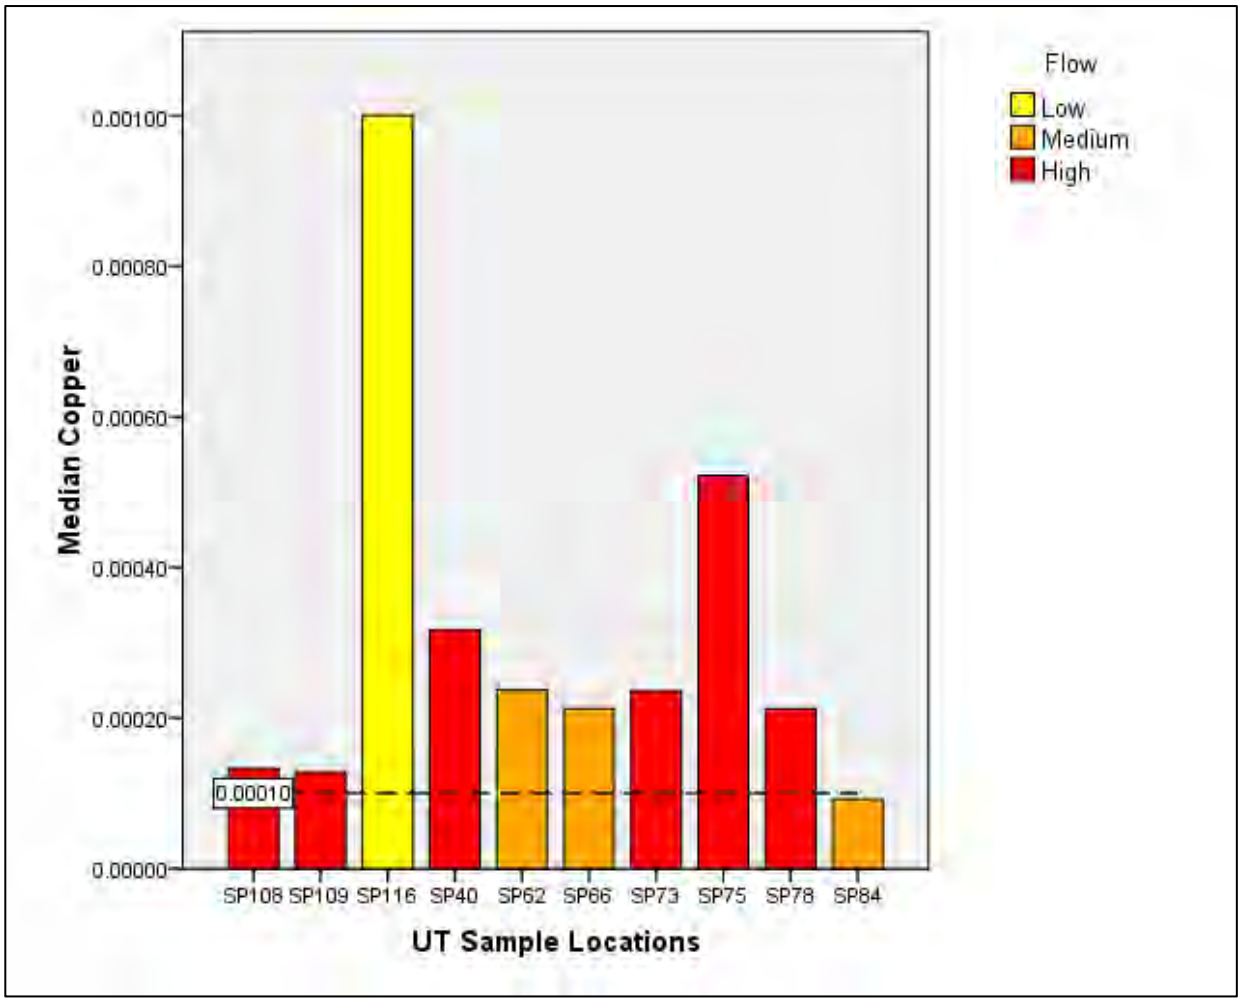

FIGURE 9.1-242
Copper Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

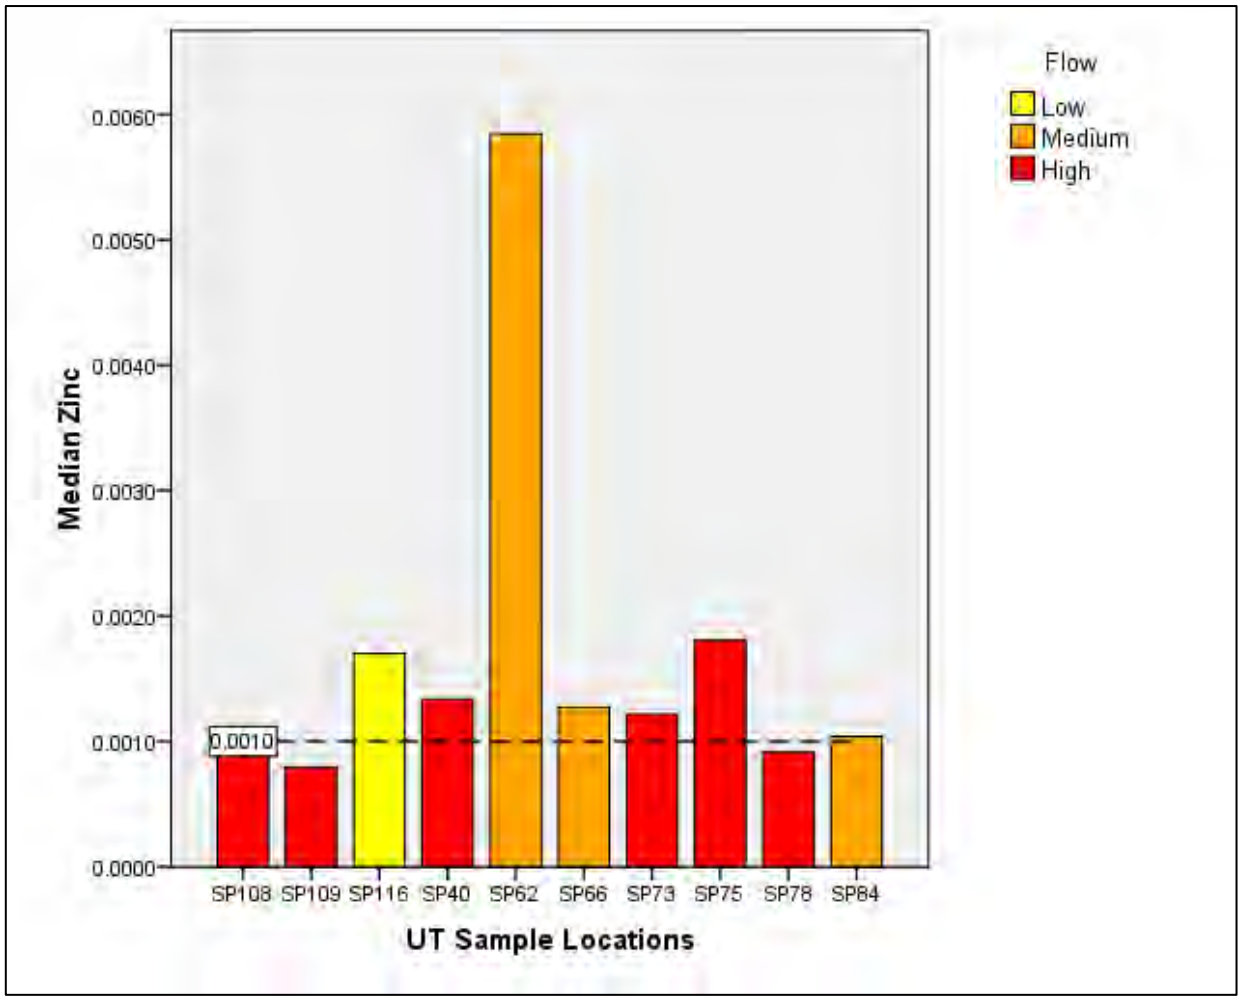

FIGURE 9.1-243
Zinc Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

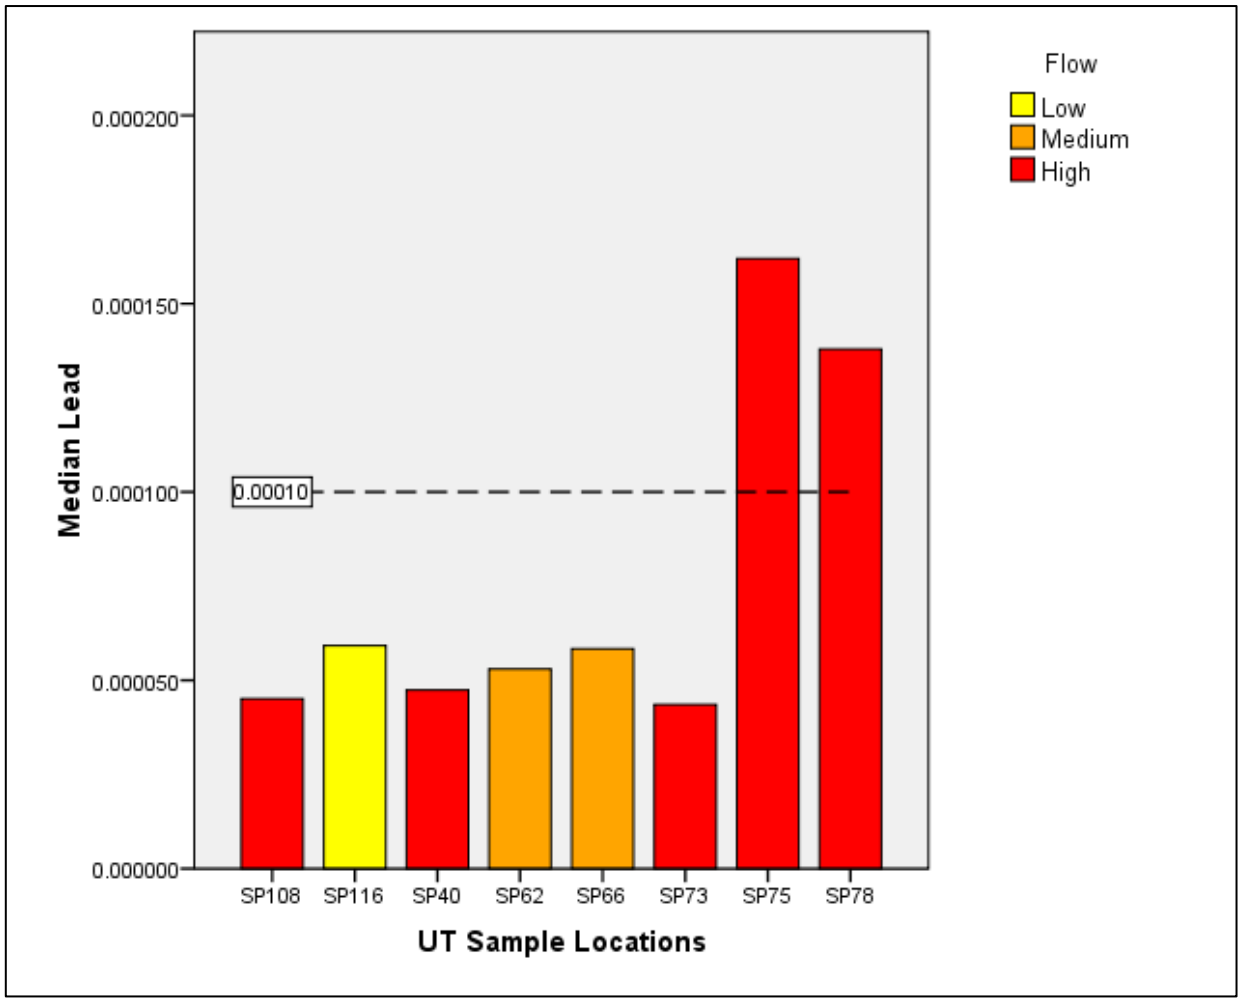

FIGURE 9.1-244
Lead Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

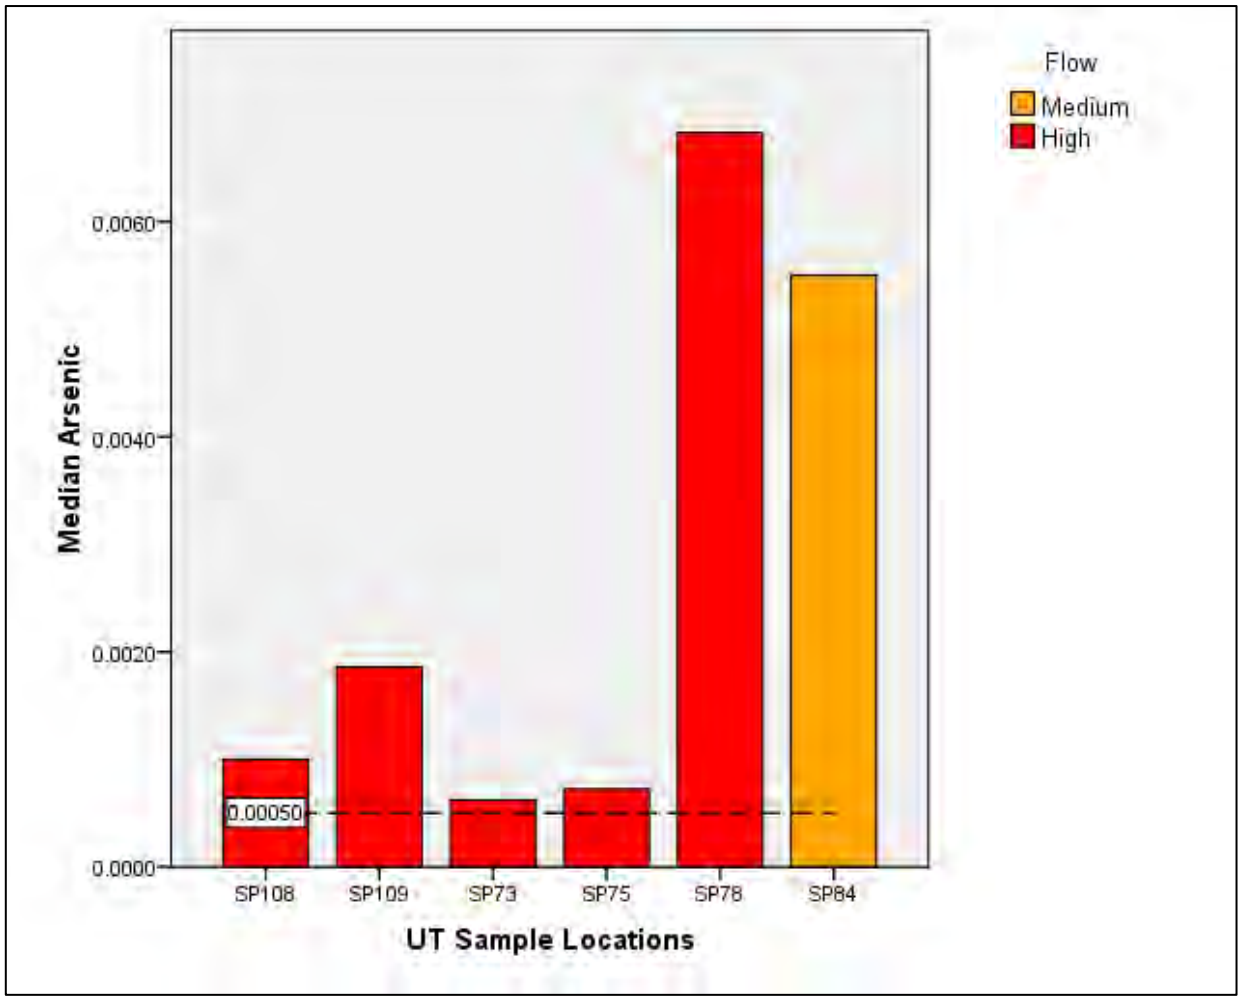

FIGURE 9.1-245
Arsenic Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

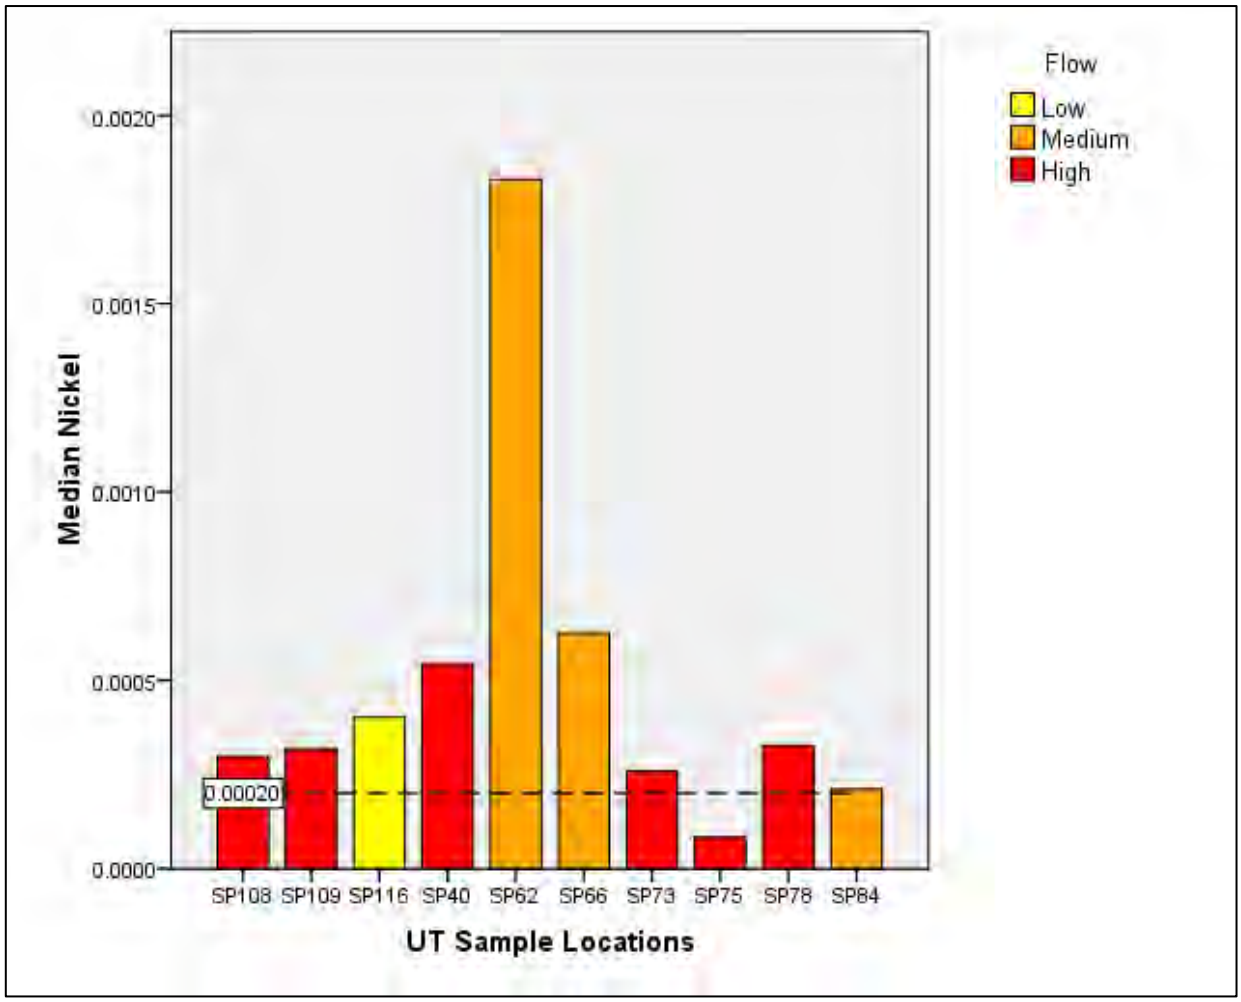

FIGURE 9.1-246
Nickel Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

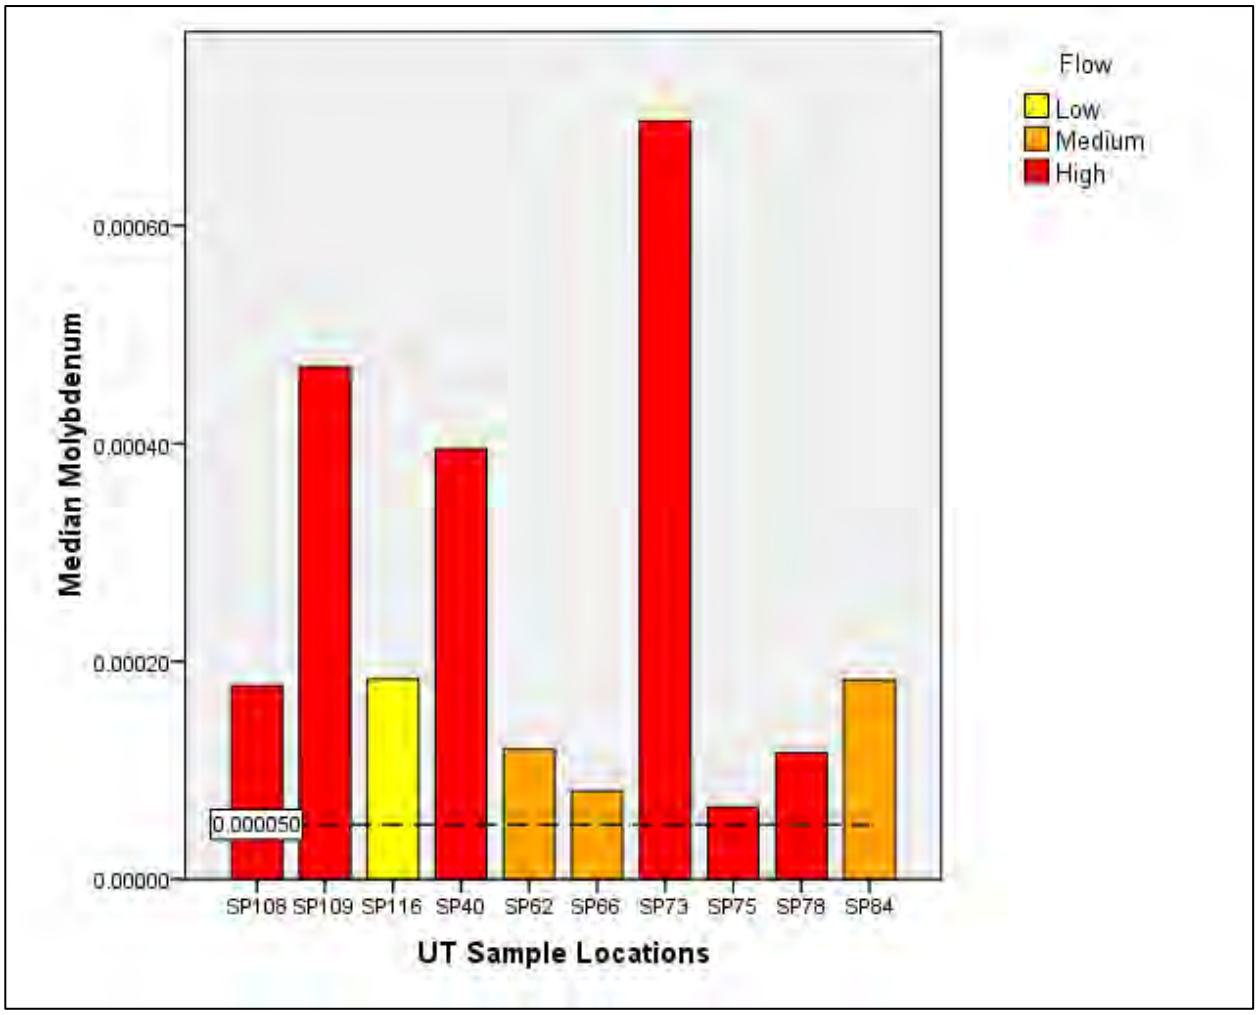

FIGURE 9.1-247
Molybdenum Concentrations and Flow Velocity in Seeps by Location, Upper Talarik Creek Drainage

Notes:

Median concentrations are for all years (2004-2008) with available data for each sample location.

Only detected values are shown.

Analyte concentrations are in milligrams per liter (mg/L).

The method reporting limit (MRL) is indicated by a line and text box within the body of the figure.

Flow velocity groups are: Highest: >5 L/s, Moderate: 1-5 L/s, Low: <1.0 L/s, Very Low: <0.1 L/s during the low flow season as defined in Table 9.1-4.

UT = Upper Talarik Creek.

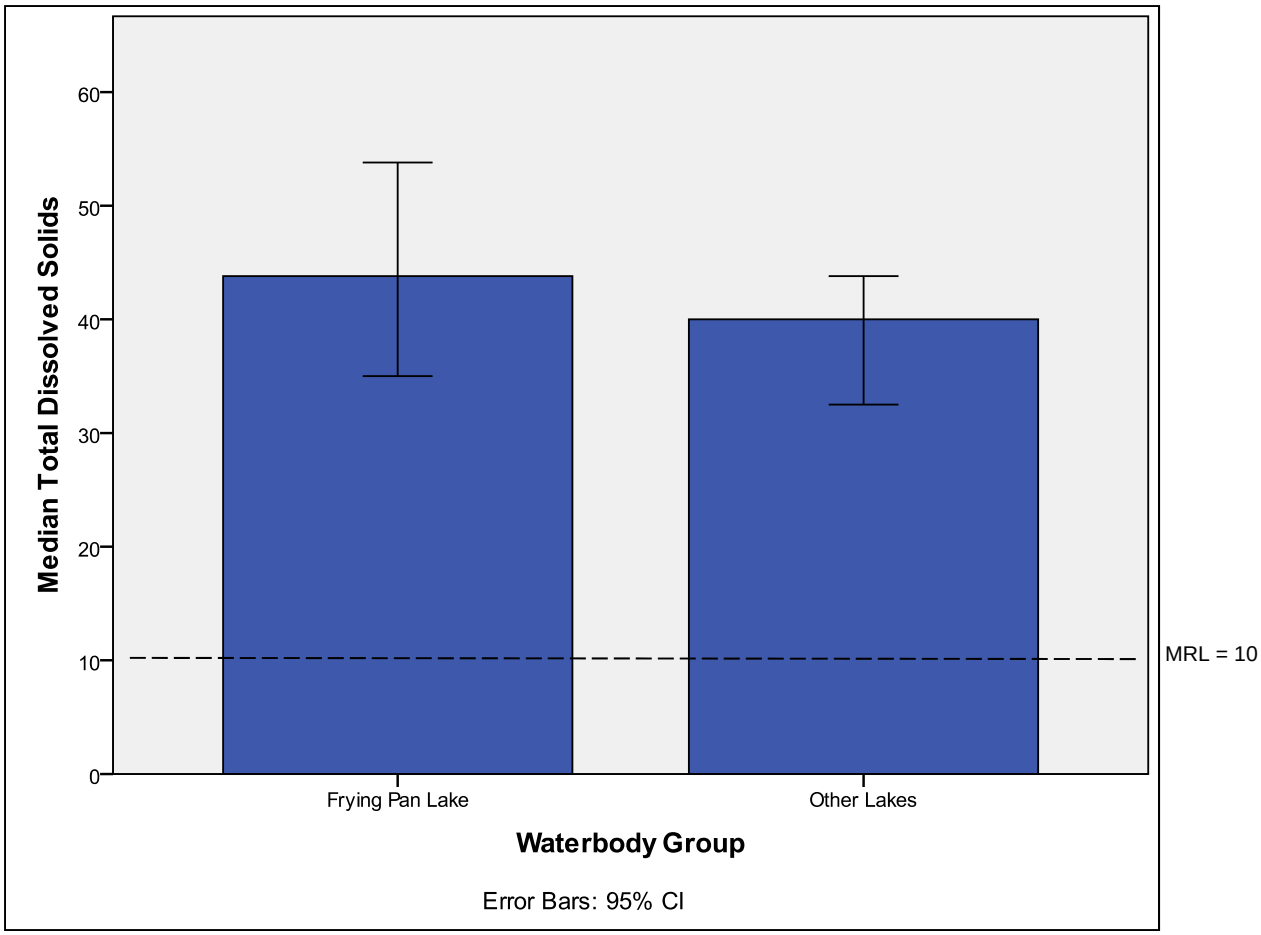

FIGURE 9.1-248
Total Dissolved Solids Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

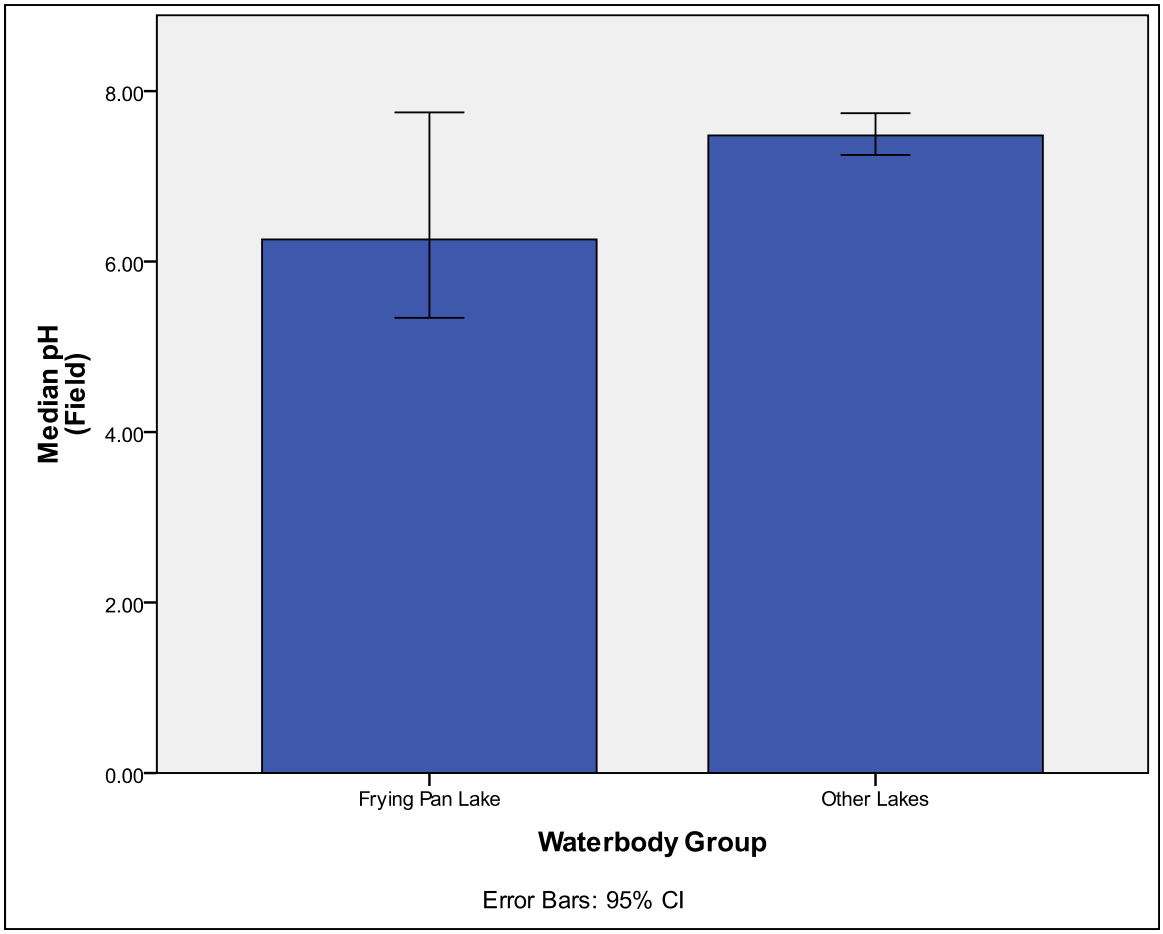

FIGURE 9.1-249
pH (Field) in Surface Water in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in standard pH units.
CI = confidence interval.

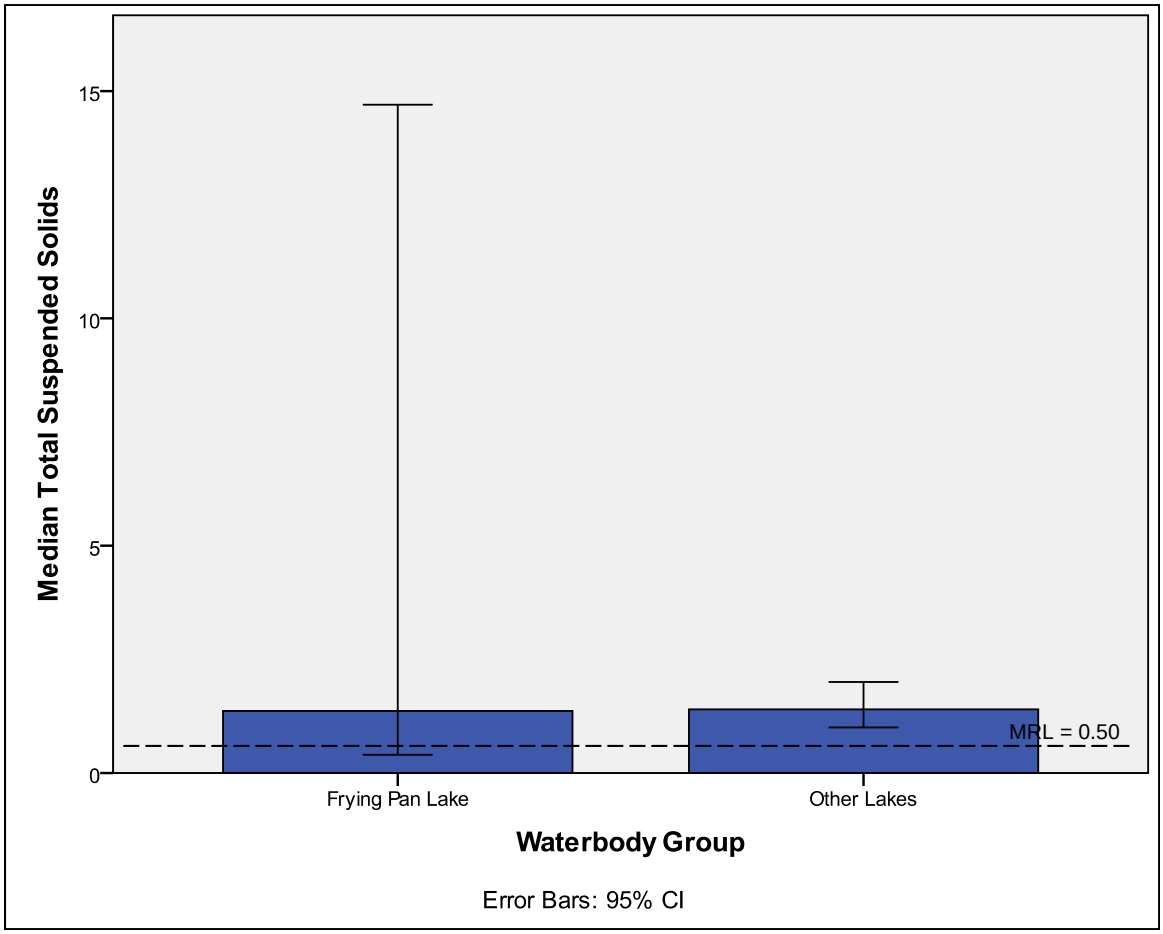

FIGURE 9.1-250
Total Suspended Solids Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

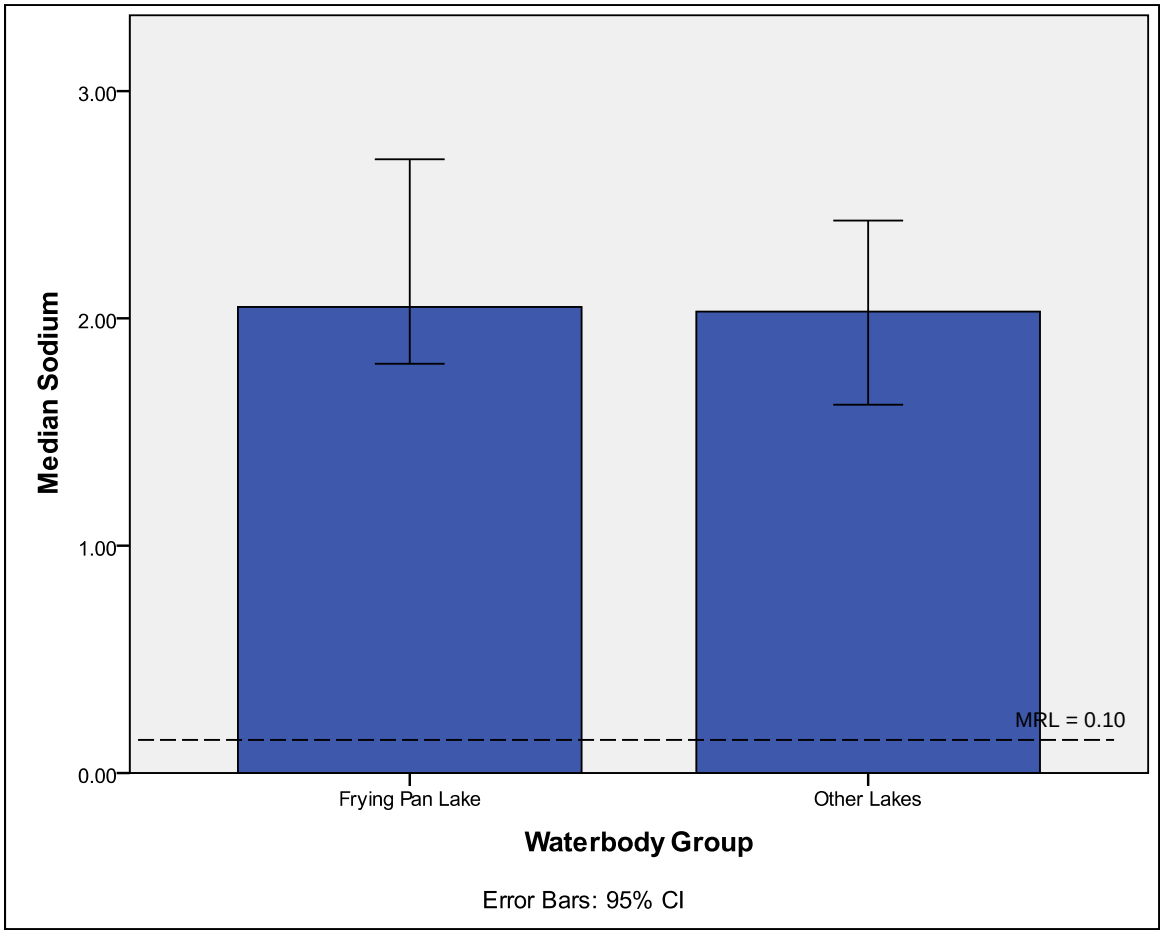

FIGURE 9.1-251
Sodium Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

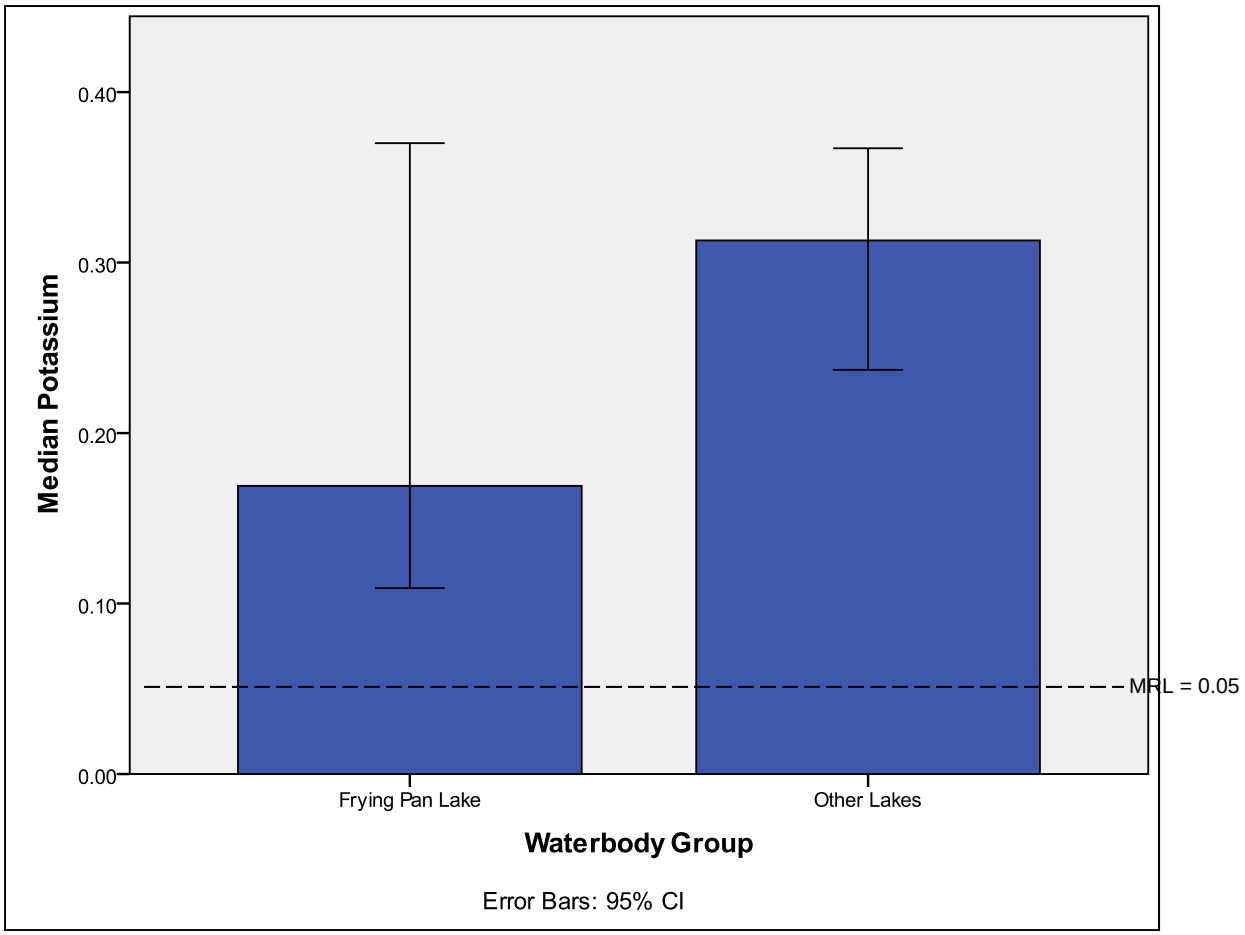

FIGURE 9.1-252
Potassium Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

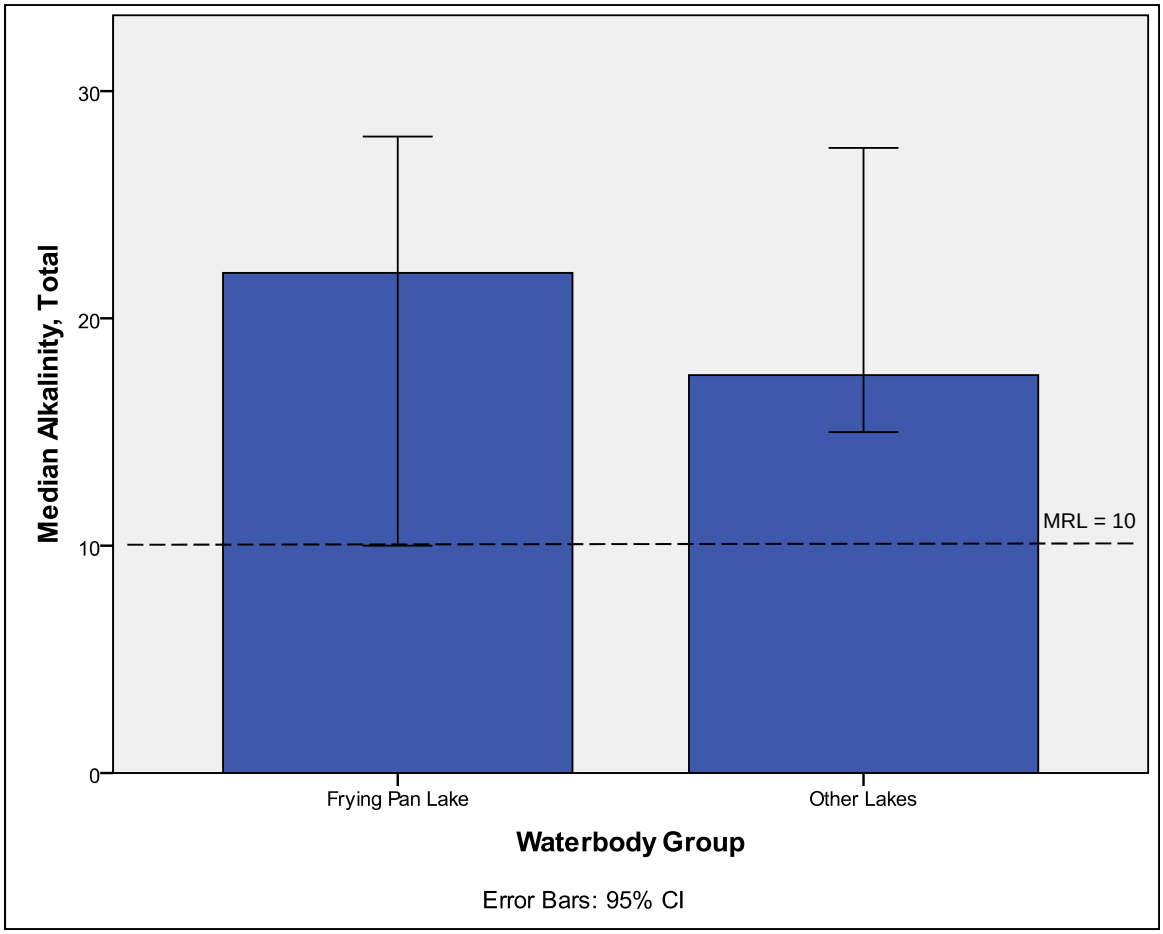

FIGURE 9.1-253
Alkalinity Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

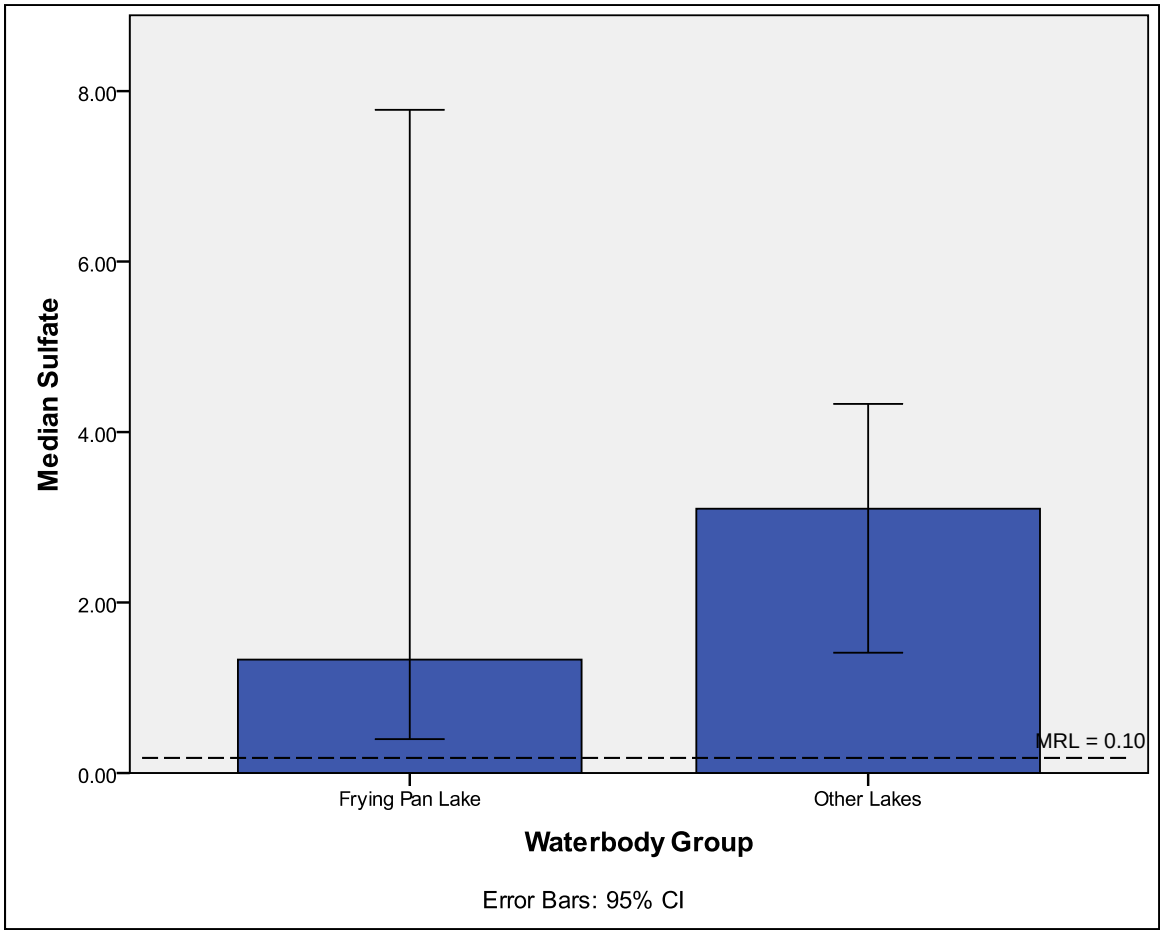

FIGURE 9.1-254
Sulfate Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

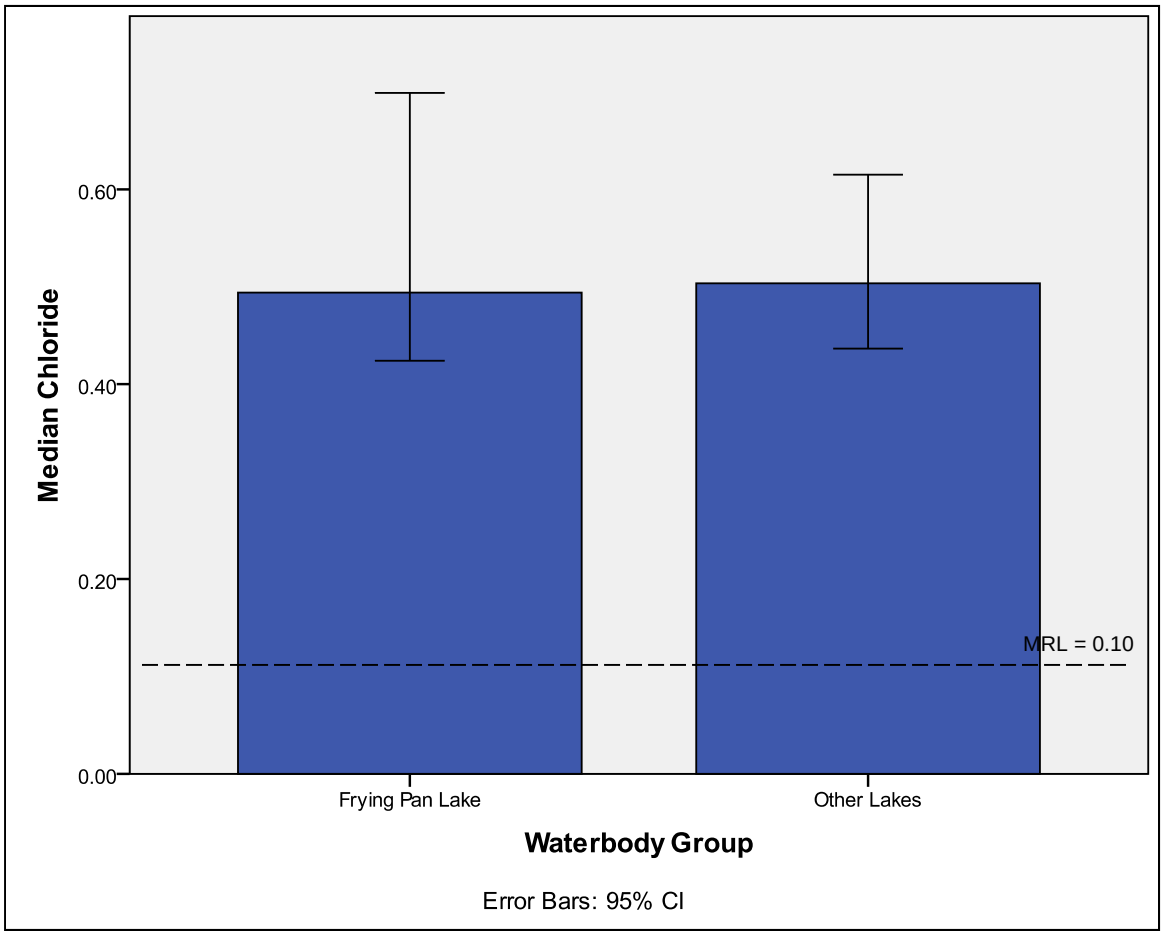

FIGURE 9.1-255
Chloride Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

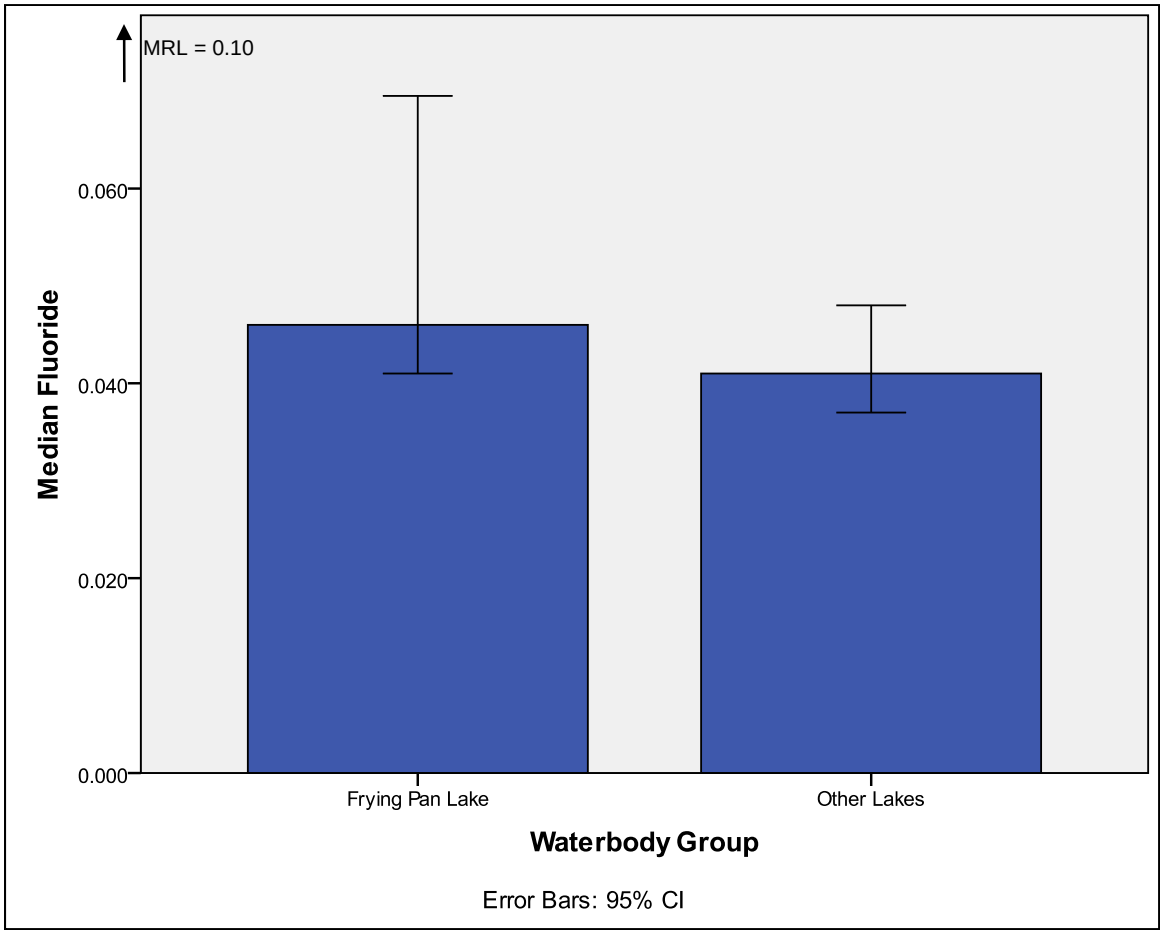

FIGURE 9.1-256
Fluoride Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

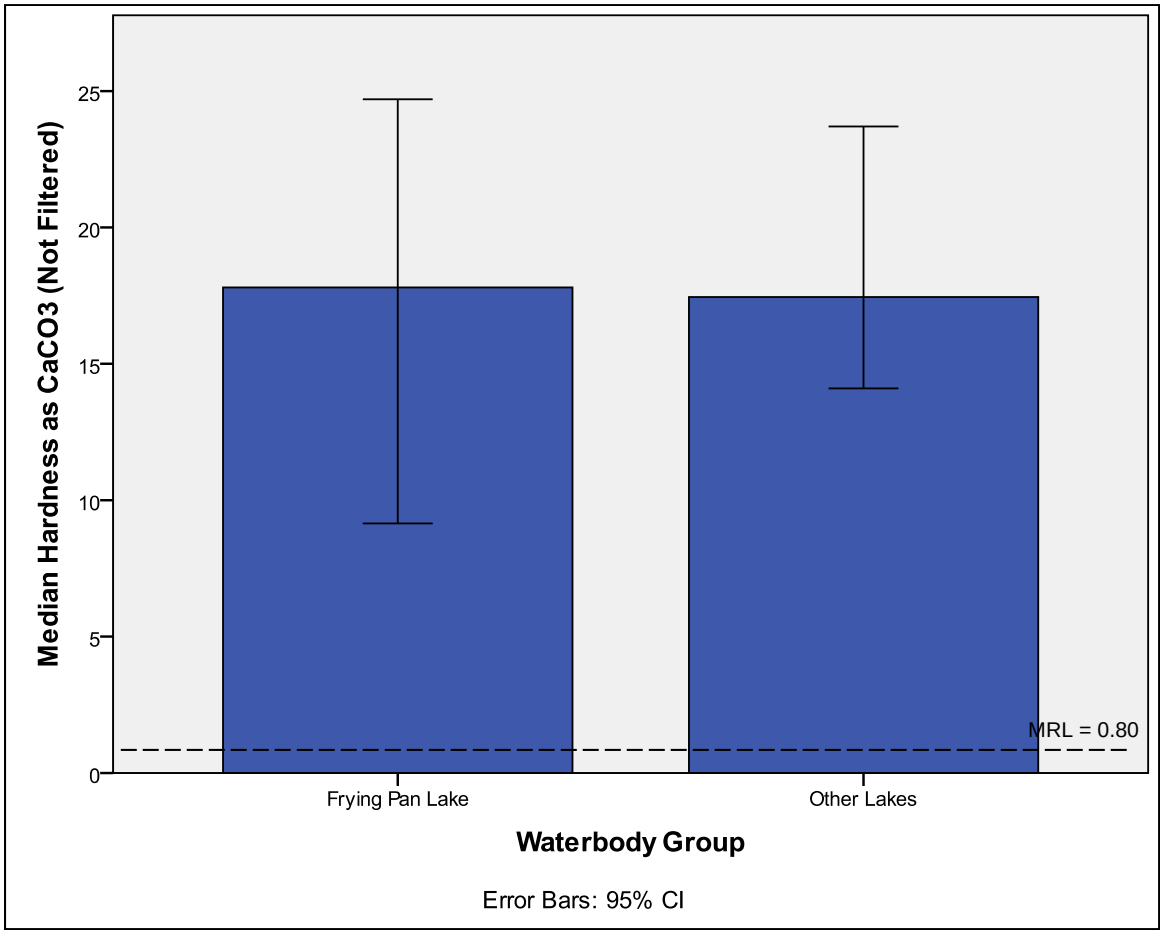

FIGURE 9.1-257
Hardness (as $CaCO_3$) Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

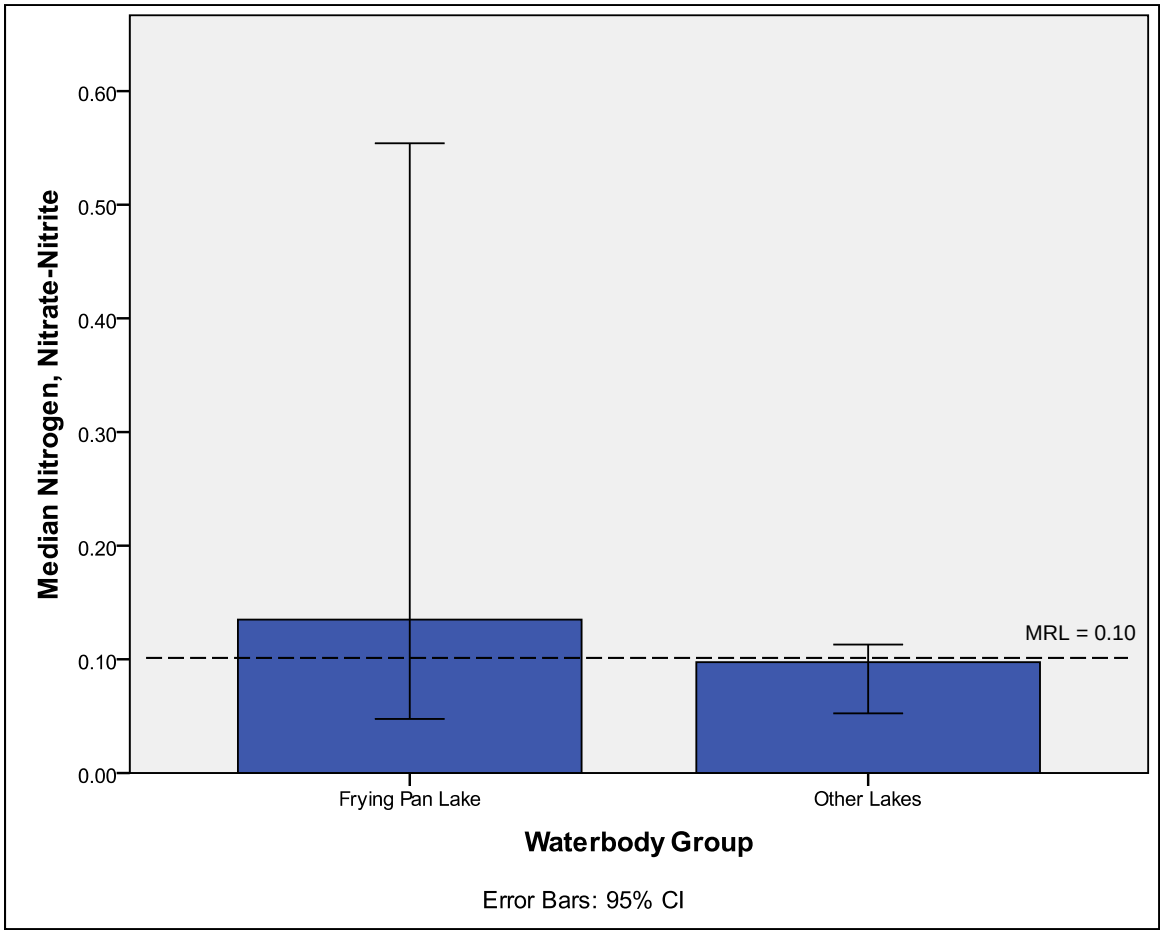

FIGURE 9.1-258
Total Nitrate+Nitrite (as N) Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

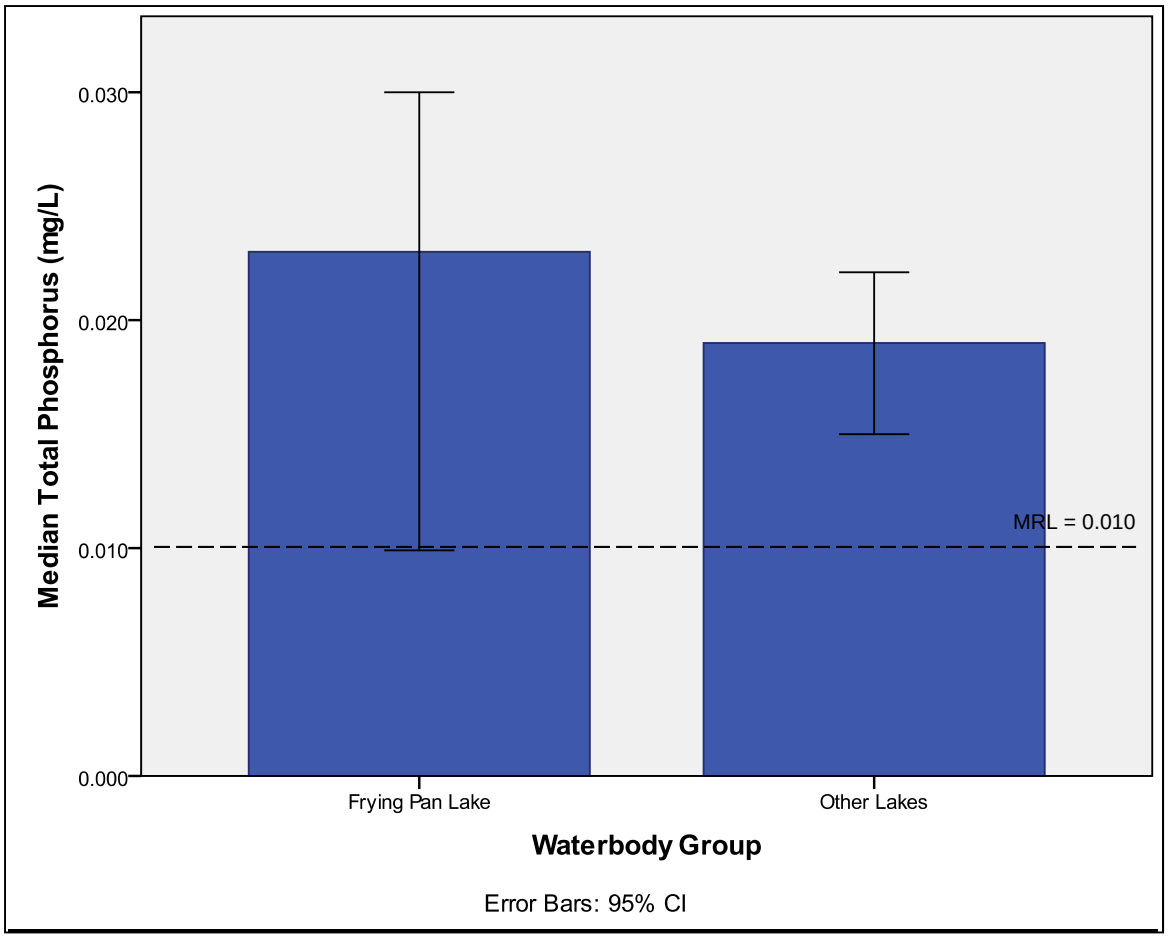

FIGURE 9.1-259
Total Phosphorus Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

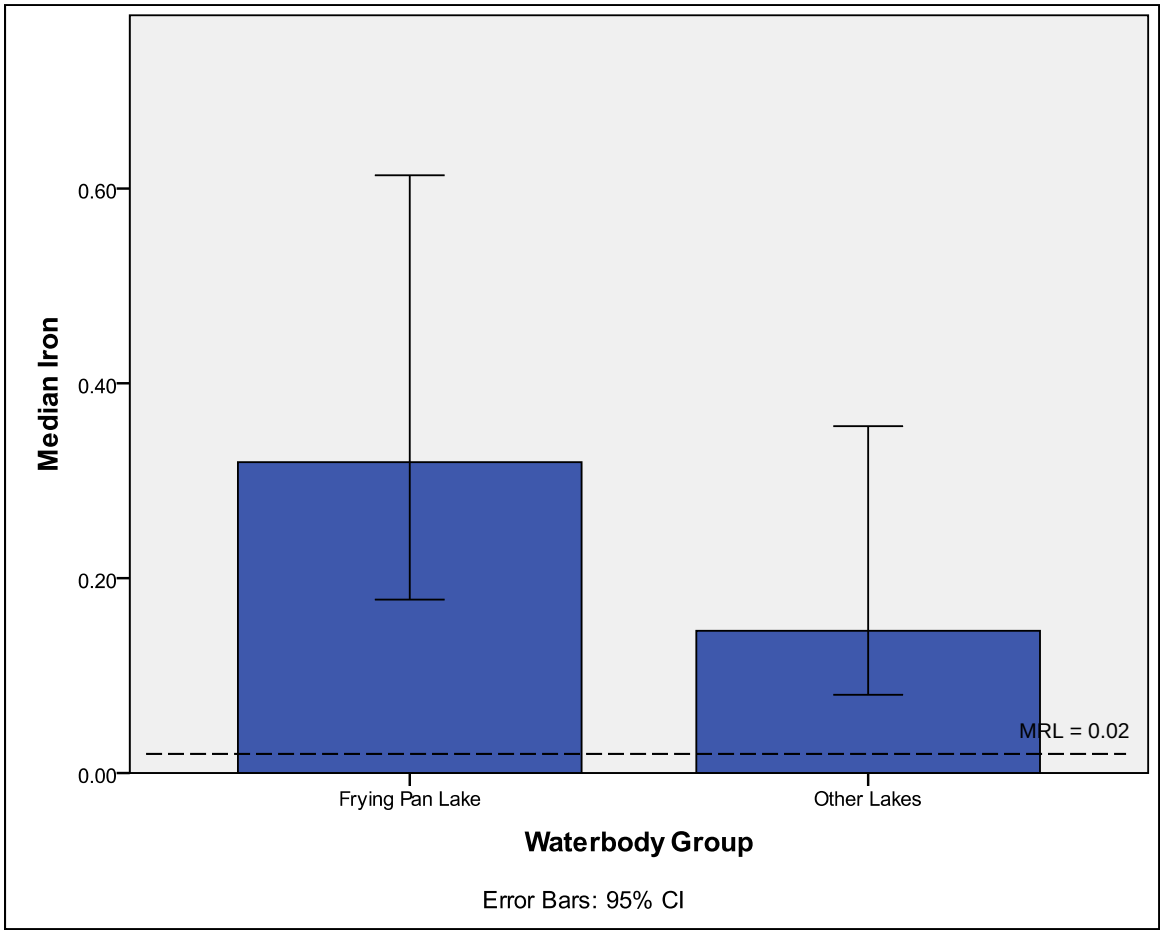

FIGURE 9.1-260
Iron Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

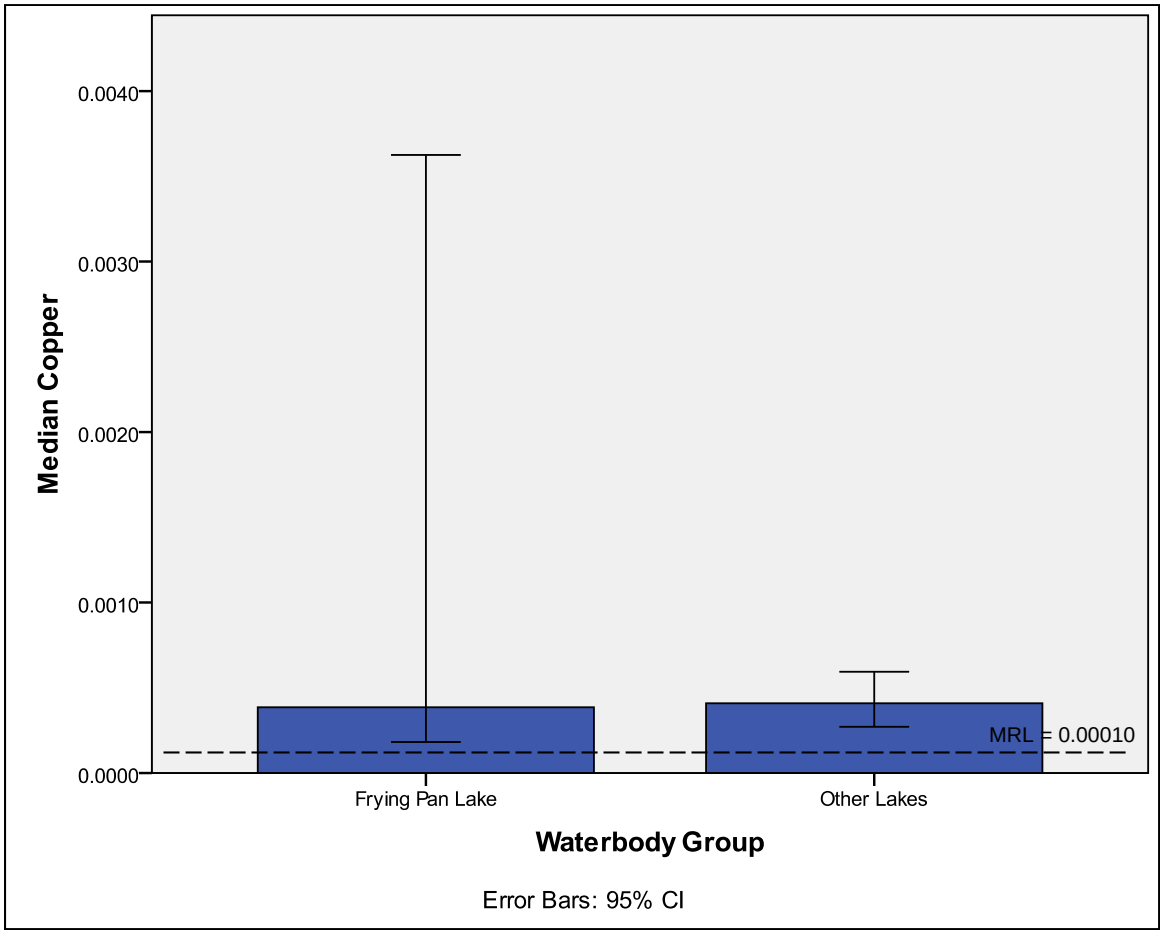

FIGURE 9.1-261
Copper Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

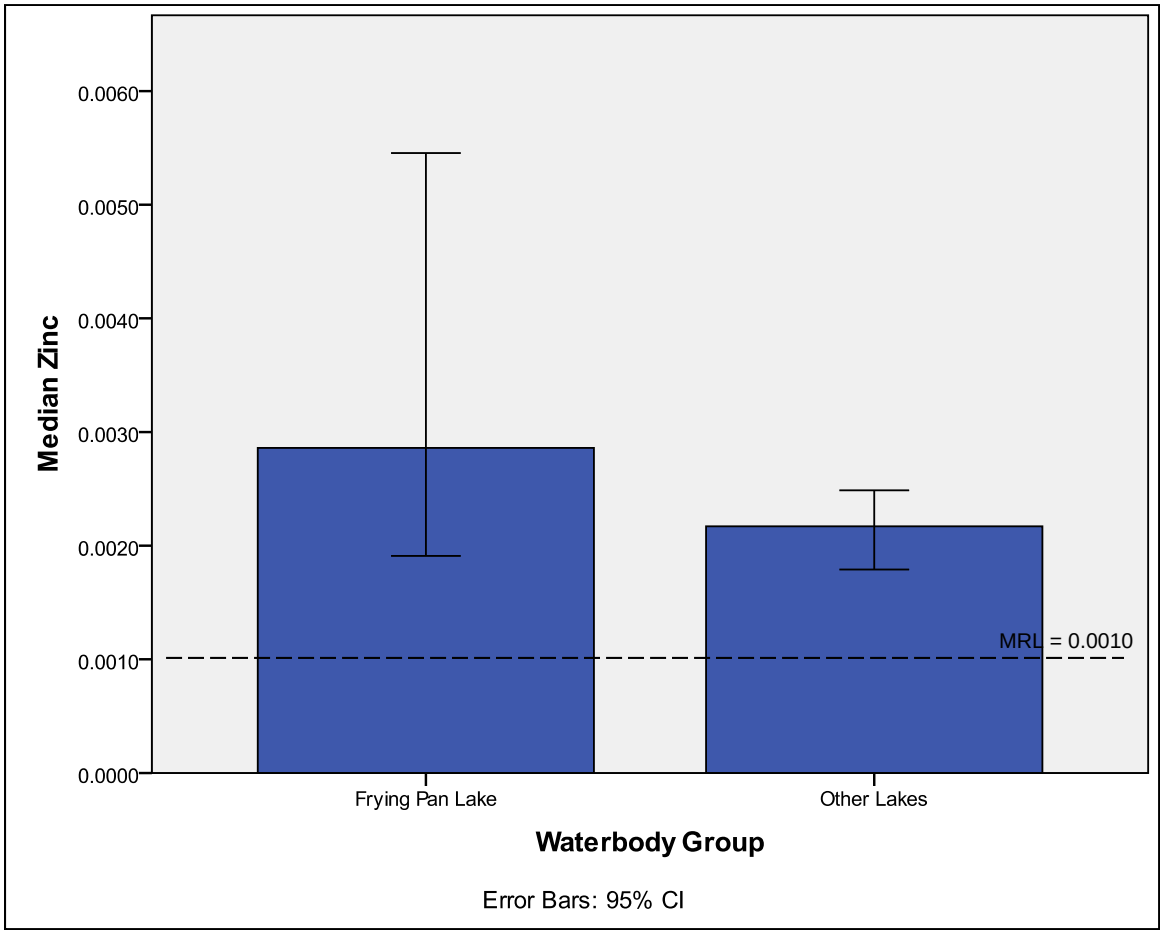

FIGURE 9.1-262
Zinc Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

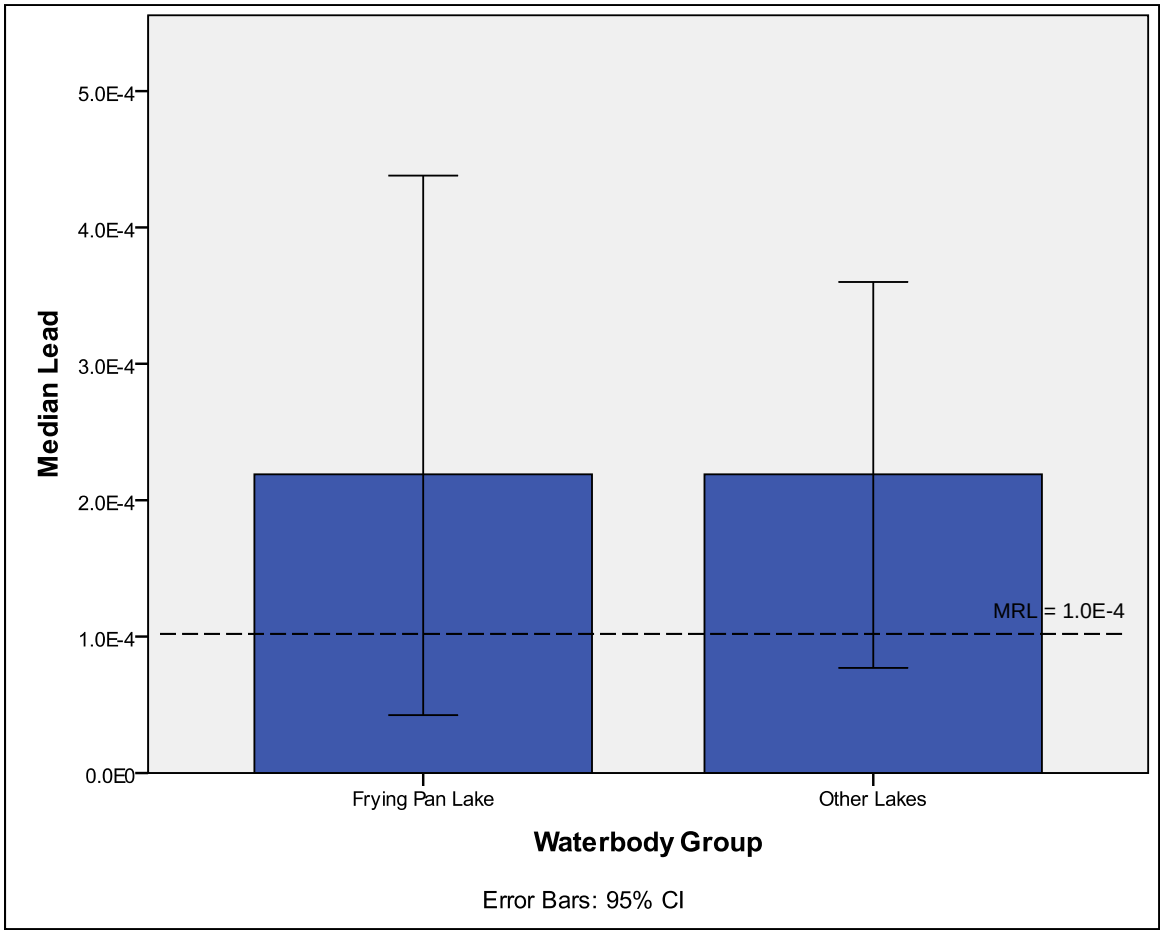

FIGURE 9.1-263
Lead Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

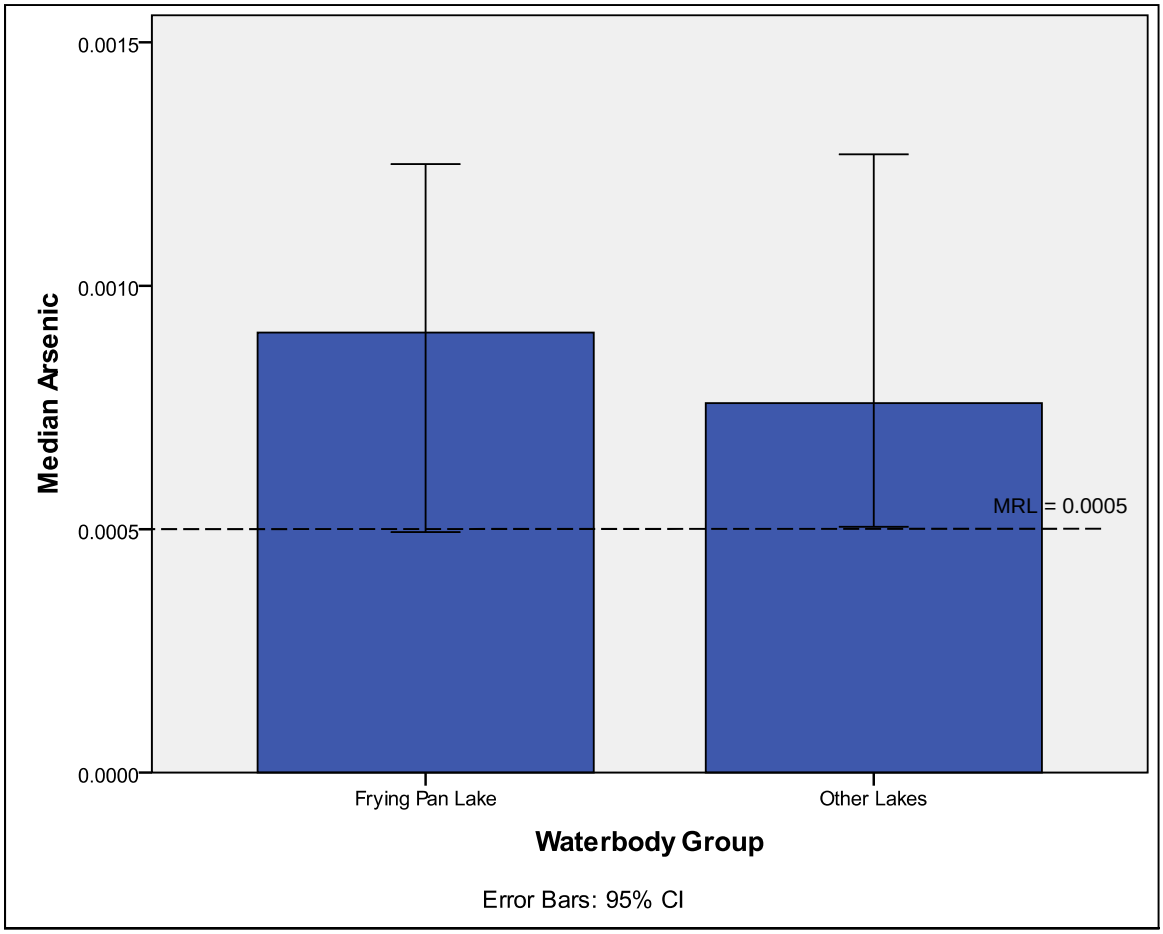

FIGURE 9.1-264
Arsenic Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

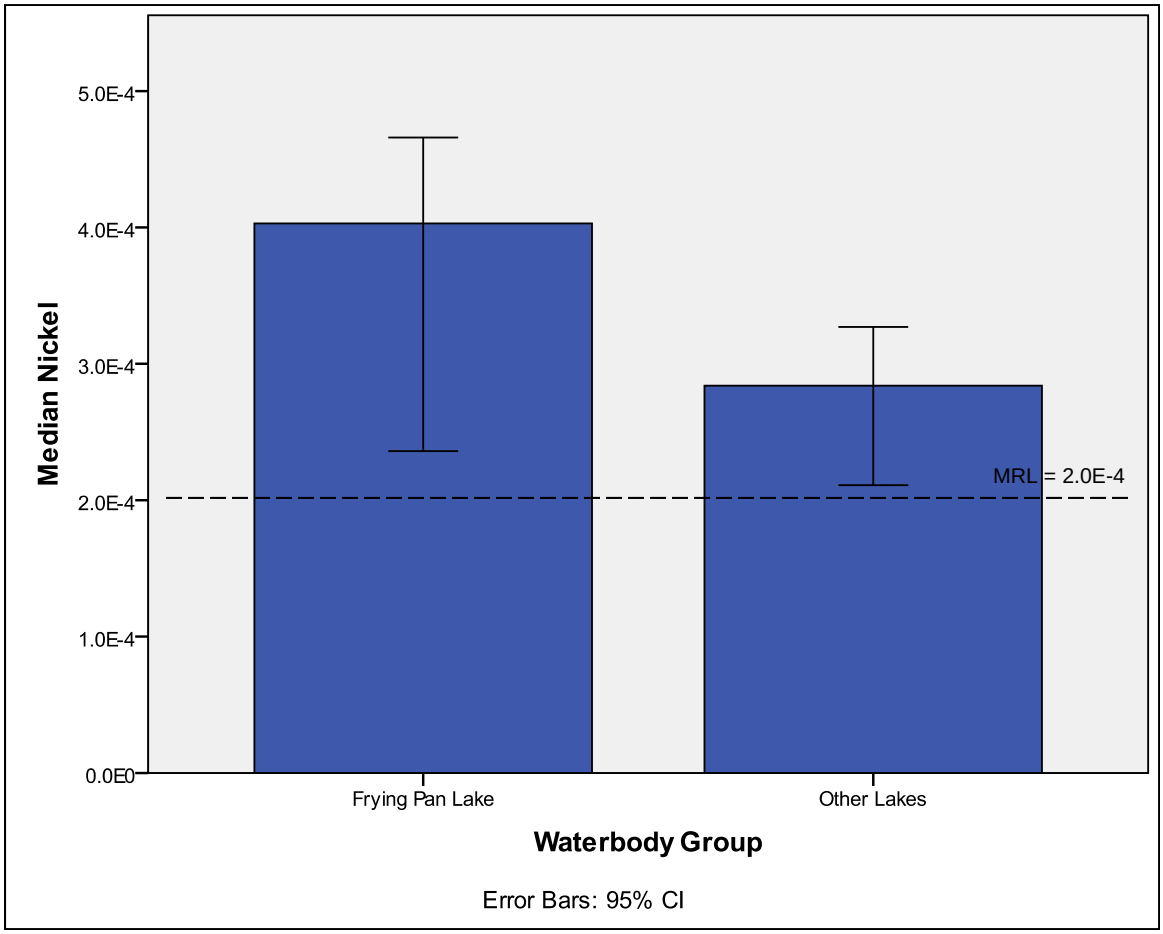

FIGURE 9.1-265
Nickel Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

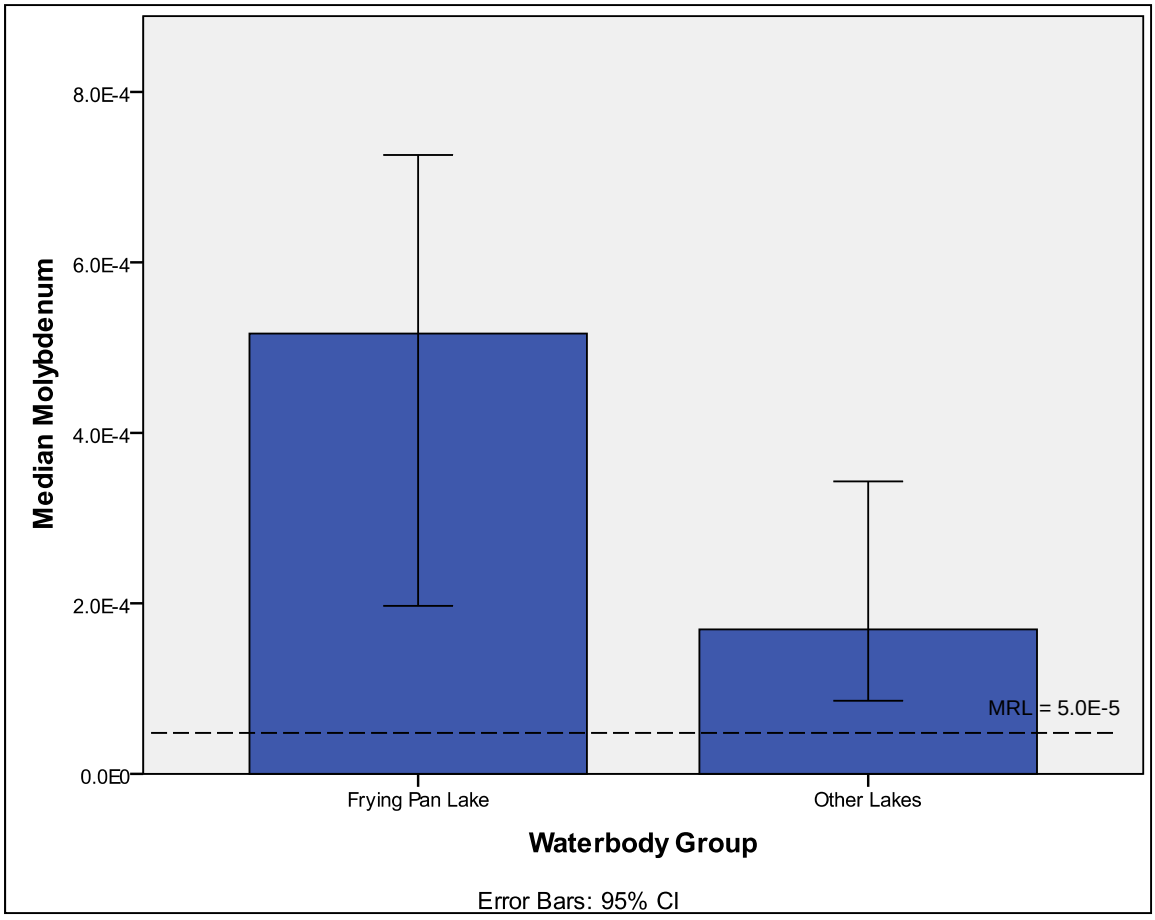

FIGURE 9.1-266
Molybdenum Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:
Median concentrations represent samples collected in July and August of 2006 and 2007.
Only detected values are shown.
Analyte concentrations are in milligrams per liter (mg/L).
CI = confidence interval.
MRL = method reporting limit.

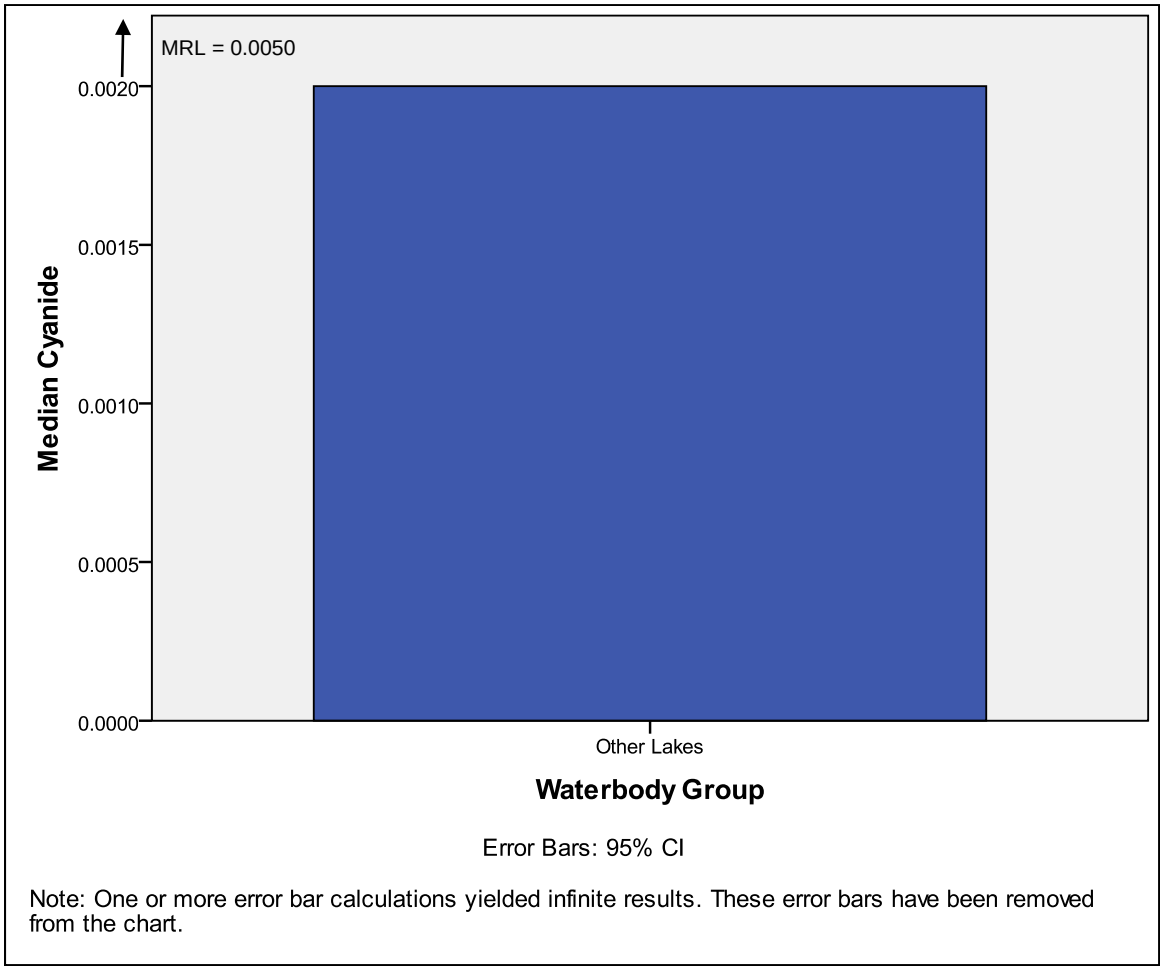

FIGURE 9.1-267
Total Cyanide Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:

Median concentrations represent samples collected in July and August of 2006 and 2007.

Only detected values are shown. Cyanide was not detected in Frying Pan Lake. Cyanide was detected only once in Other Lakes; error bars are therefore not relevant for these locations.

Analyte concentrations are in milligrams per liter (mg/L).

CI = confidence interval.

MRL = method reporting limit.

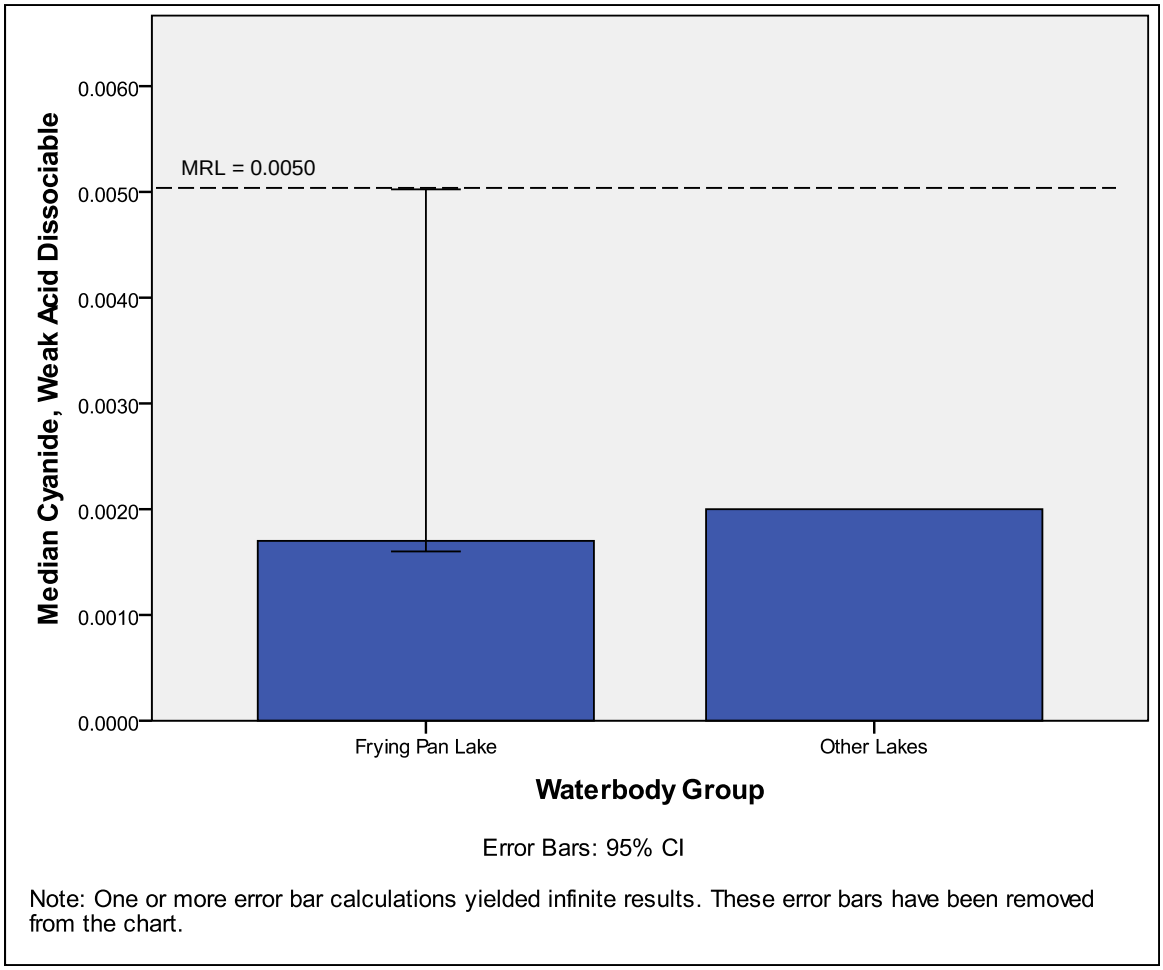

FIGURE 9.1-268
Cyanide, Weak Acid Dissociable (WAD) Surface Water Concentrations in Frying Pan Lake and Other Lakes in the Study Area

Notes:

Median concentrations represent samples collected in July and August of 2006 and 2007.

Only detected values are shown. Cyanide (weak acid dissociable) was detected only once in Other Lakes; error bars are therefore not relevant for these locations.

Analyte concentrations are in milligrams per liter (mg/L).

CI = confidence interval.

MRL = method reporting limit.

APPENDICES

Key:

Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:

(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.

Key:

Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:

(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.

Key:

Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:

(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.

Key:

Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:

(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.

Key:

Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:

(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.
