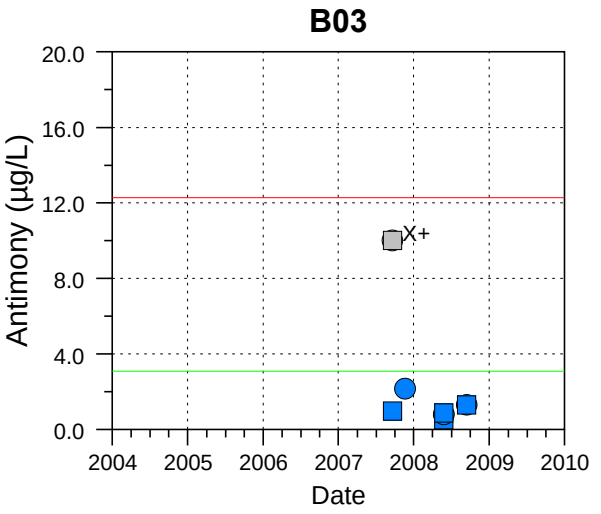
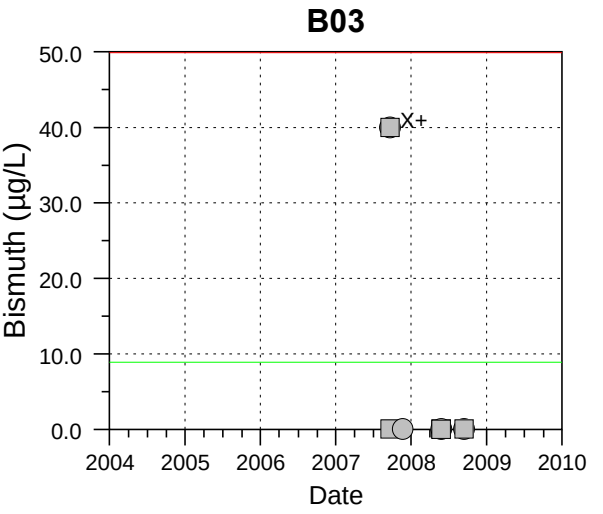
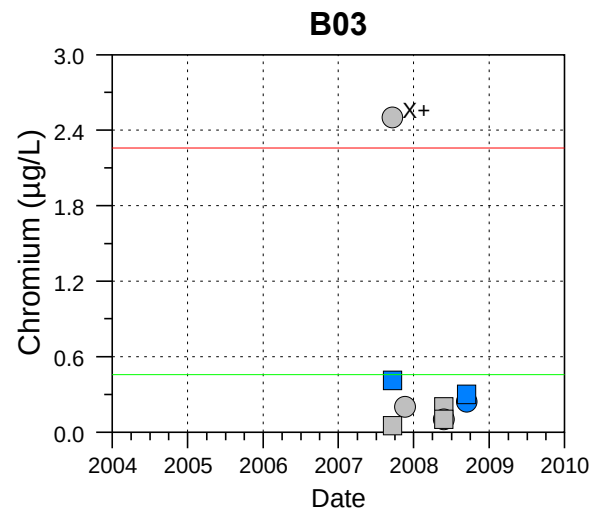
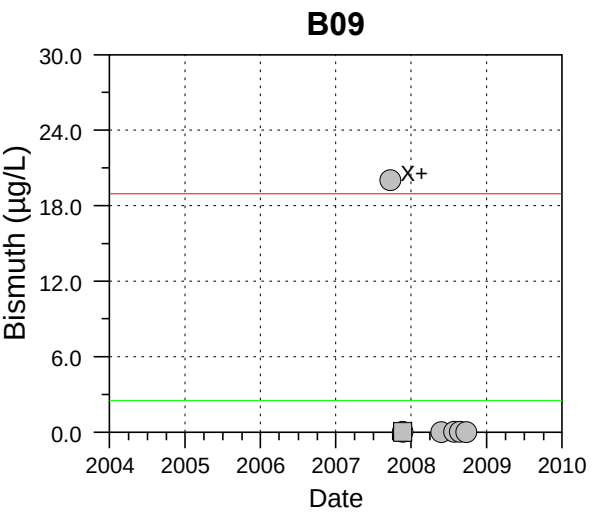
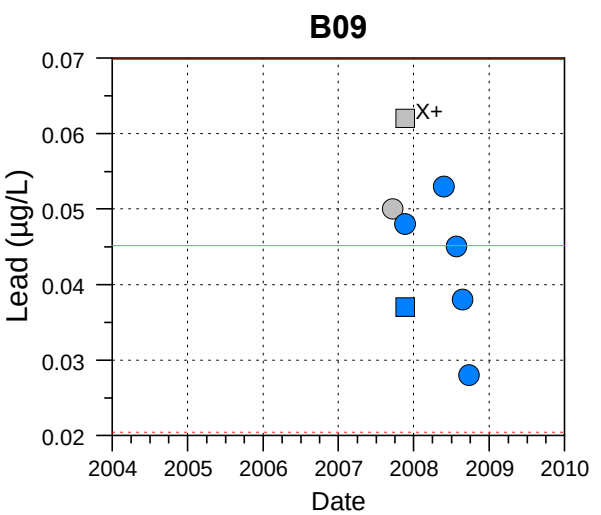
Table 9.1D-3: List of Outliers and Documented Elevated Values, Dissolved Concentrations 74
Table 9.1D-4: List of Outliers and Documented Elevated Values, Total Concentrations 90

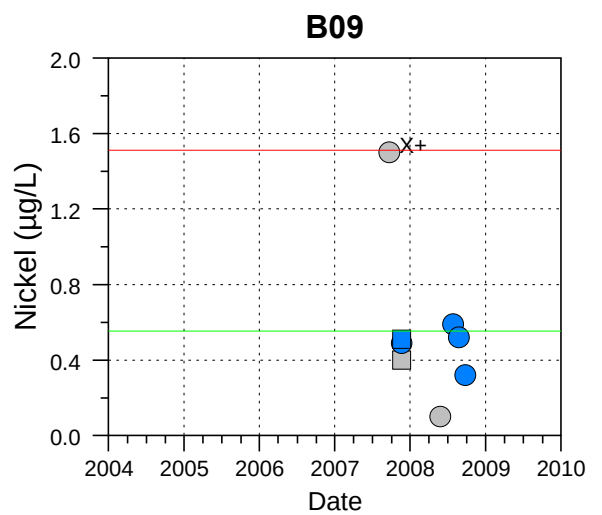












Legend

- Analytical Result
- Quality Control Sample Result
- Not Detected
- Upper 98% Confidence Level
- Mean
- Lower 98% Confidence Level

X+ outlier, very high value

Notes:

1) Non detect (ND) values are treated as values in the data analysis at 0.5 x MDL (Method Detection Limit) for unflagged data or 0.5 x MRL (Method Reporting Limit) in the case of U-flagged data (Data below the MRL).

2) Some non detect values were marked as outliers because they were higher than other actual data values, or because they were much higher than other non-detect values, and therefore would have skewed the data analysis.

3) ug/L = micrograms per liter

X+ outlier, very high value

Notes:

1) Non detect (ND) values are treated as values in the data analysis at 0.5 x MDL (Method Detection Limit) for unflagged data or 0.5 x MRL (Method Reporting Limit) in the case of U-flagged data (Data below the MRL).

2) Some non detect values were marked as outliers because they were higher than other actual data values, or because they were much higher than other non-detect values, and therefore would have skewed the data analysis.

3) ug/L = micrograms per liter

2) Some non detect values were marked as outliers because they were higher than other actual data values, or because they were much higher than other non-detect values, and therefore would have skewed the data analysis.

3) ug/L = micrograms per liter

THE pebble PARTNERSHIP

Appendix 9.1D
Control Plots Showing Outliers at Individual Sampling Locations for Total Constituents

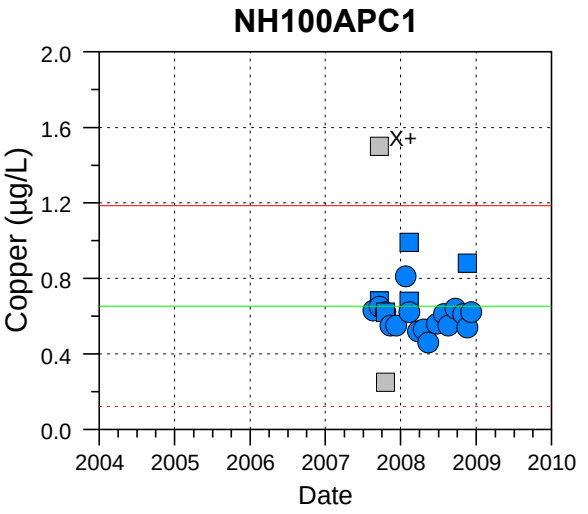
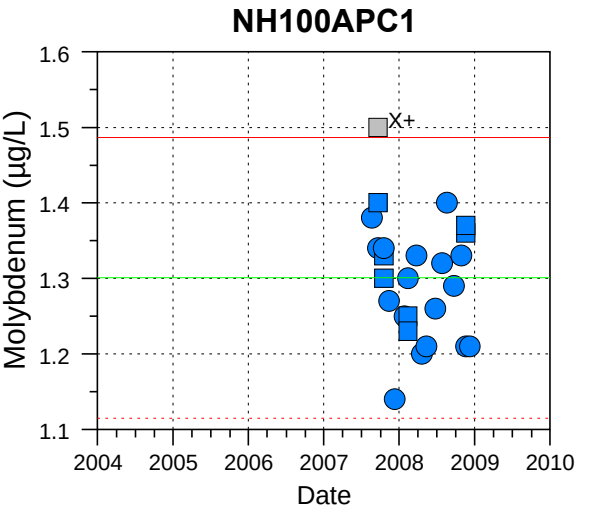
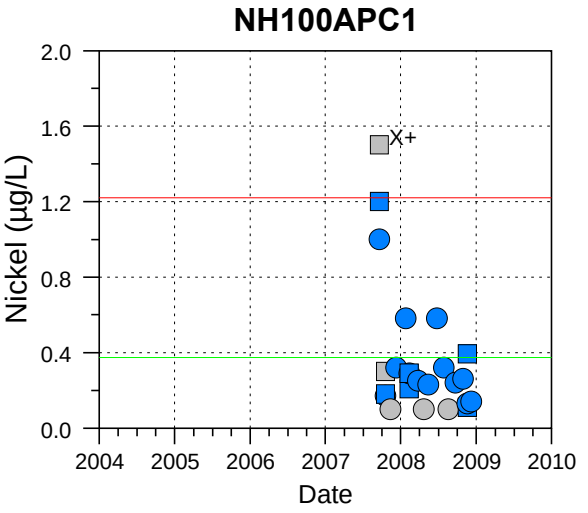
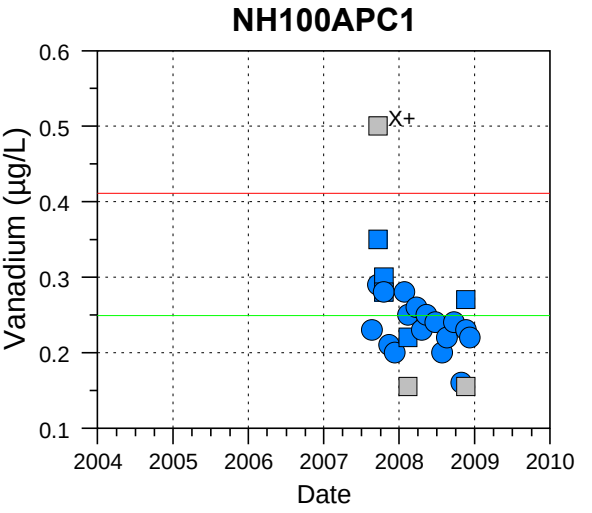
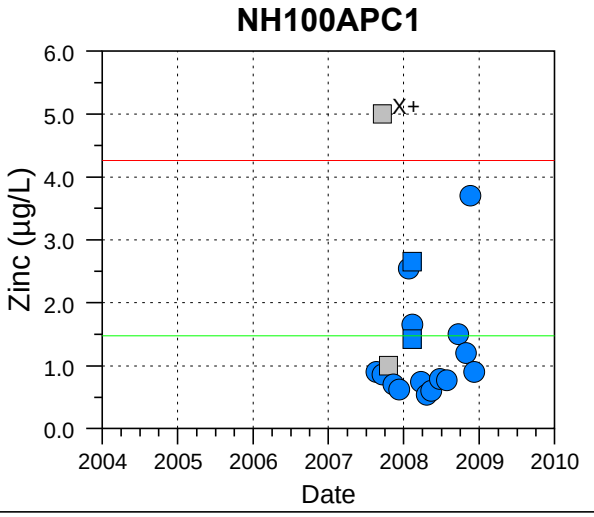
File: 7126	Date: Jul 07, 2011
Version: 1	Author: SWS-ca

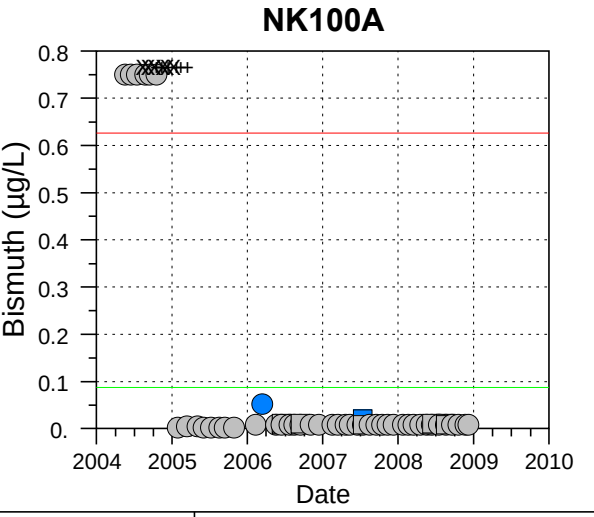












Legend

- Analytical Result
- Quality Control Sample Result
- Not Detected
- Upper 98% Confidence Level
- Mean
- Lower 98% Confidence Level

X+ outlier, very high value

Notes:

1) Non detect (ND) values are treated as values in the data analysis at 0.5 x MDL (Method Detection Limit) for unflagged data or 0.5 x MRL (Method Reporting Limit) in the case of U-flagged data (Data below the MRL).

2) Some non detect values were marked as outliers because they were higher than other actual data values, or because they were much higher than other non-detect values, and therefore would have skewed the data analysis.

3) ug/L = micrograms per liter

River and Creek Spatial Water Quality Regression Plots: North Fork Koktuli River, South Fork Koktuli River, and Upper Talarik Creek, Mine Study Area 2004-2008

TABLE OF CONTENTS

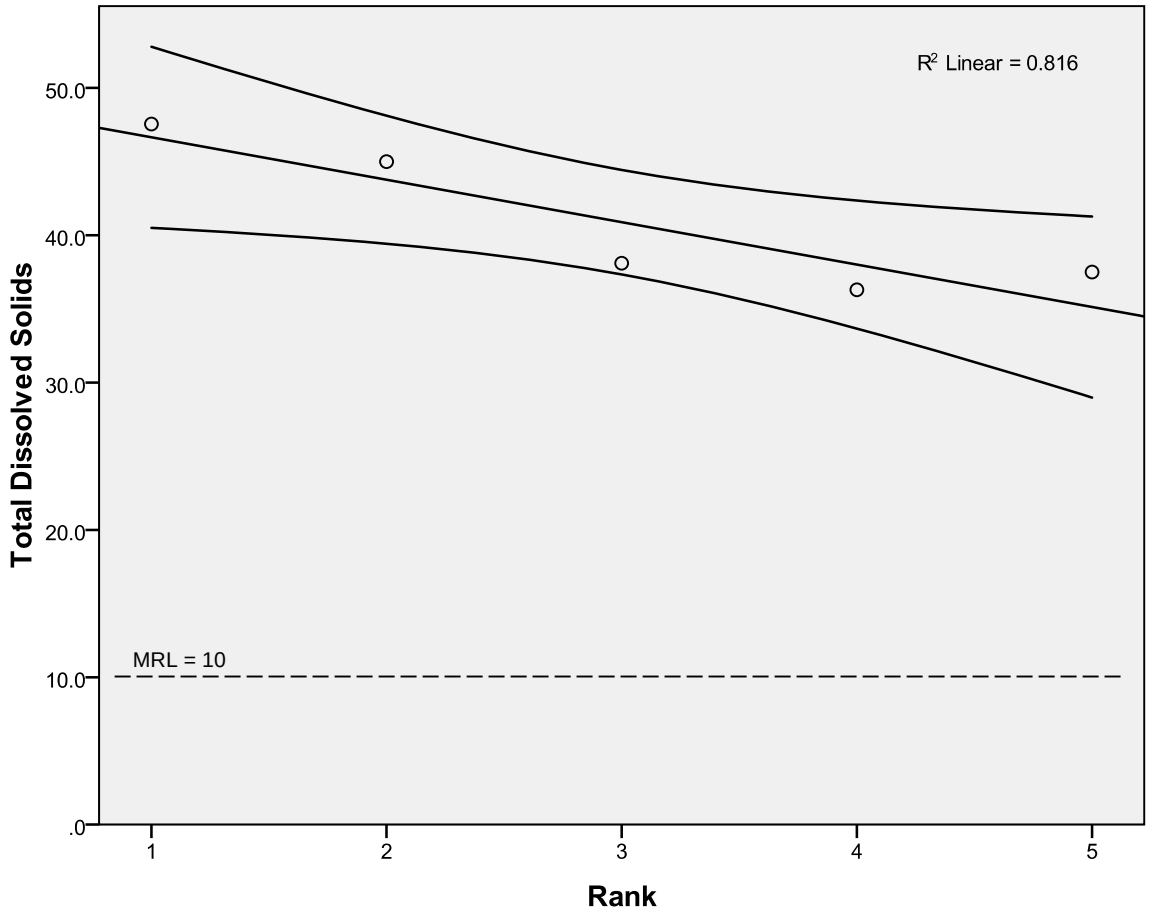
NORTH FORK KOKTULI RIVER……1

SOUTH FORK KOKTULI RIVER……..…5

UPPER TALARIK CREEK……..18

NORTH FORK KOKTULI RIVER

NORTH FORK KOKTULI RIVER



Location [a]	Rank [b]
NK100D	1
NK100C	2
NK100B	3
NK100A1	4
NK100A	5

Notes:

a. Only main stem sample locations are shown.

b. Ranks begin with most upstream location (1 = most upstream, 5 = most downstream).

Notes:

Median concentrations (in milligrams per liter [mg/L]) shown on y-axis; x-axis shows sample locations from upstream to downstream.

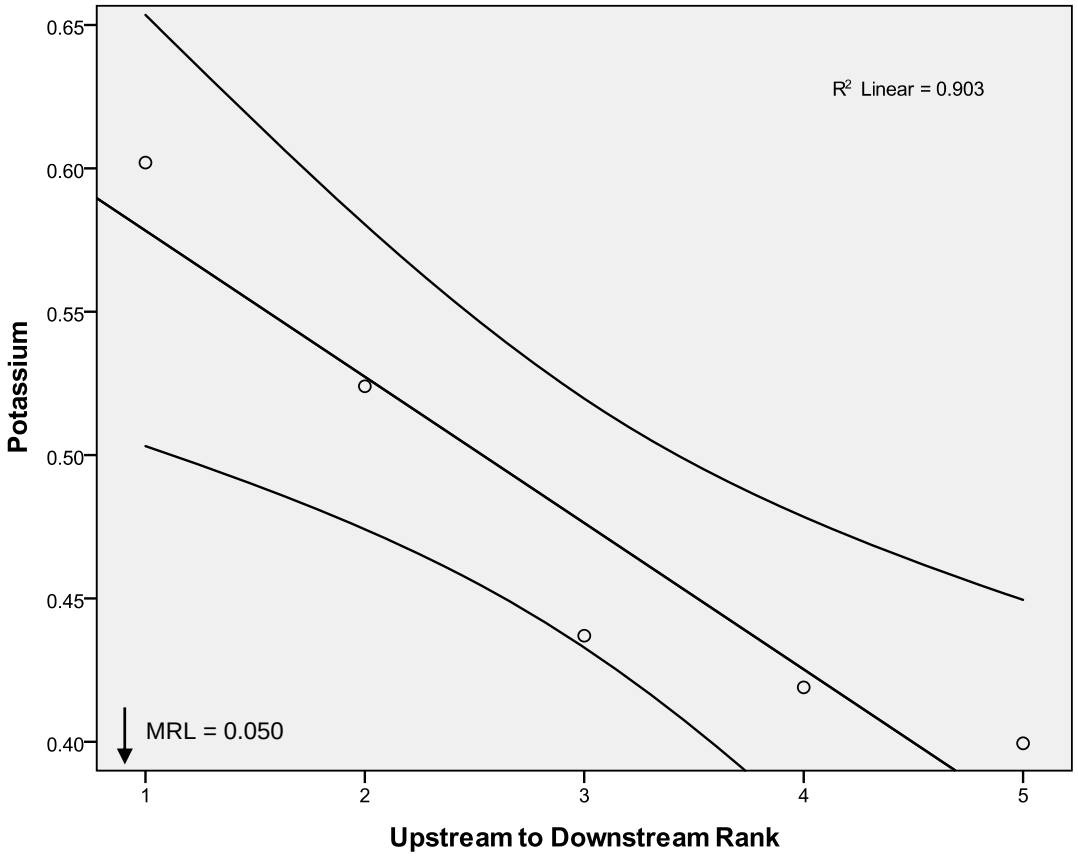
Median concentrations include only detected values.

Regression coefficient (R^2) value corresponds to best fit line.

Confidence intervals on the mean are represented by the outer lines.

MRL = method reporting limit.

NORTH FORK KOKTULI RIVER



Location [a]	Rank [b]
NK100D	1
NK100C	2
NK100B	3
NK100A1	4
NK100A	5

Notes:

a. Only main stem sample locations are shown.

b. Ranks begin with most upstream location (1 = most upstream, 5 = most downstream).

Notes:

Median concentrations (in milligrams per liter [mg/L]) shown on y-axis; x-axis shows sample locations from upstream to downstream.

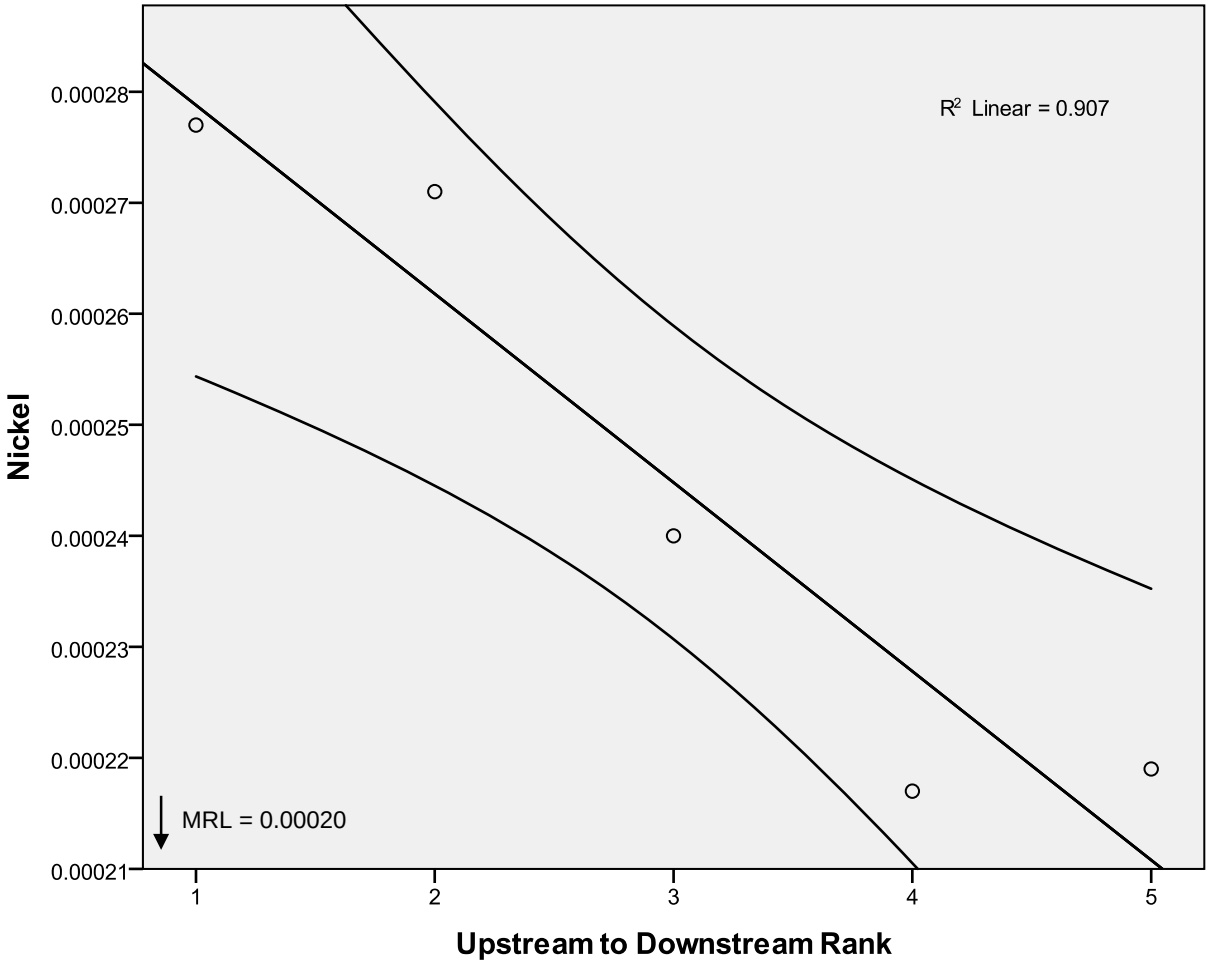
Median concentrations include only detected values.

Regression coefficient (R^2) value corresponds to best fit line.

Confidence intervals on the mean are represented by the outer lines.

MRL = method reporting limit.

NORTH FORK KOKTULI RIVER



Location [a]	Rank [b]
NK100D	1
NK100C	2
NK100B	3
NK100A1	4
NK100A	5

Notes:

a. Only main stem sample locations are shown.

b. Ranks begin with most upstream location (1 = most upstream, 5 = most downstream).

Notes:

Median concentrations (in milligrams per liter [mg/L]) shown on y-axis; x-axis shows sample locations from upstream to downstream.

Median concentrations include only detected values.

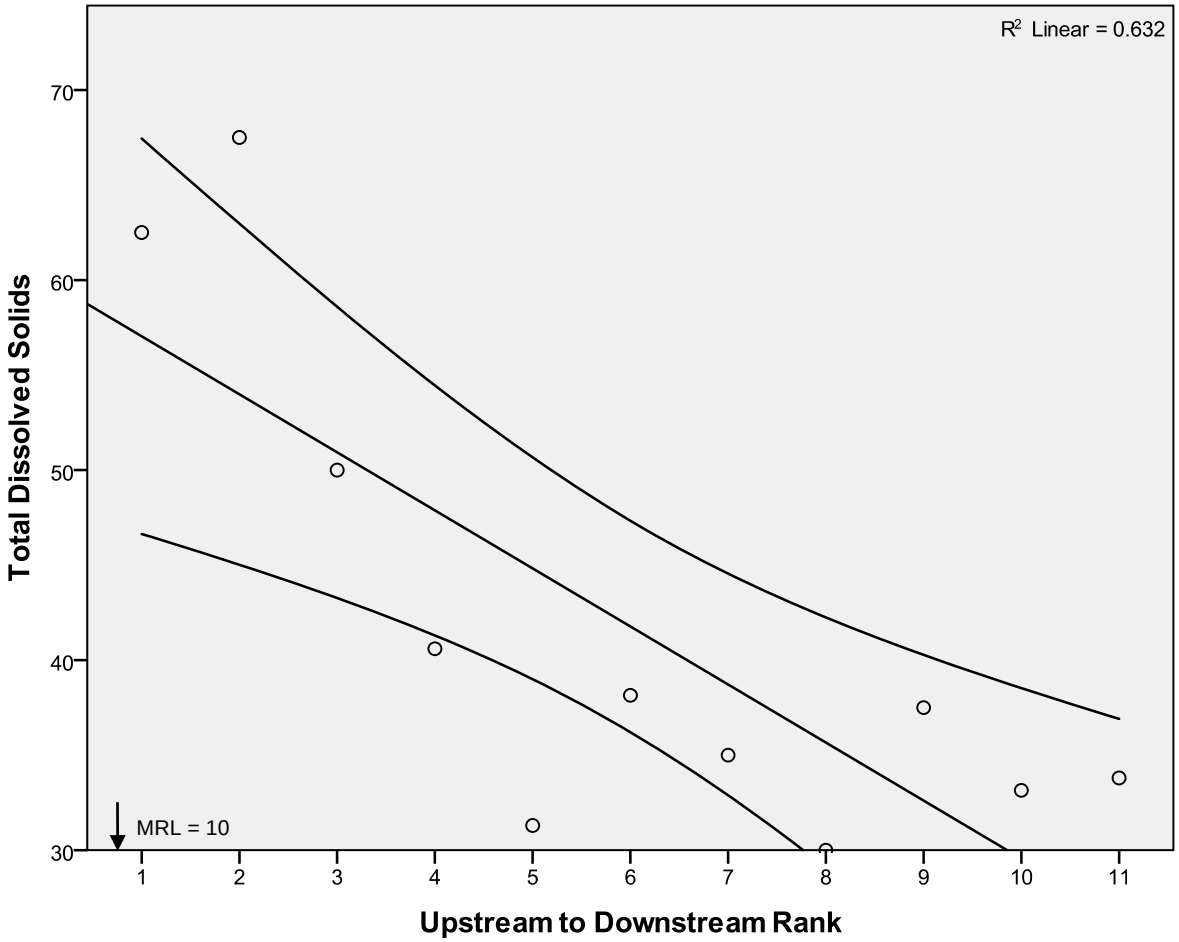
Regression coefficient (R^2) value corresponds to best fit line.

Confidence intervals on the mean are represented by the outer lines.

MRL = method reporting limit.

SOUTH FORK KOKTULI RIVER

SOUTH FORK KOKTULI RIVER



Location [a]	Rank [b]
SK100I[c]	1
SK100H[c]	2
SK100G	3
SK100F	4
SK100E	5
SK100D	6
SK100C	7
SK100B2	8
SK100B1	9
SK100B	10
SK100A	11

Notes:

a. Only main stem sample locations are shown.

b. Ranks begin with most upstream location (1 = most upstream, 11 = most downstream).

c. SK100I and SK100H were previously known as SK136B and SL136A respectively.

Notes:

Median concentrations (in milligrams per liter [mg/L]) shown on y-axis; x-axis shows sample locations from upstream to downstream.

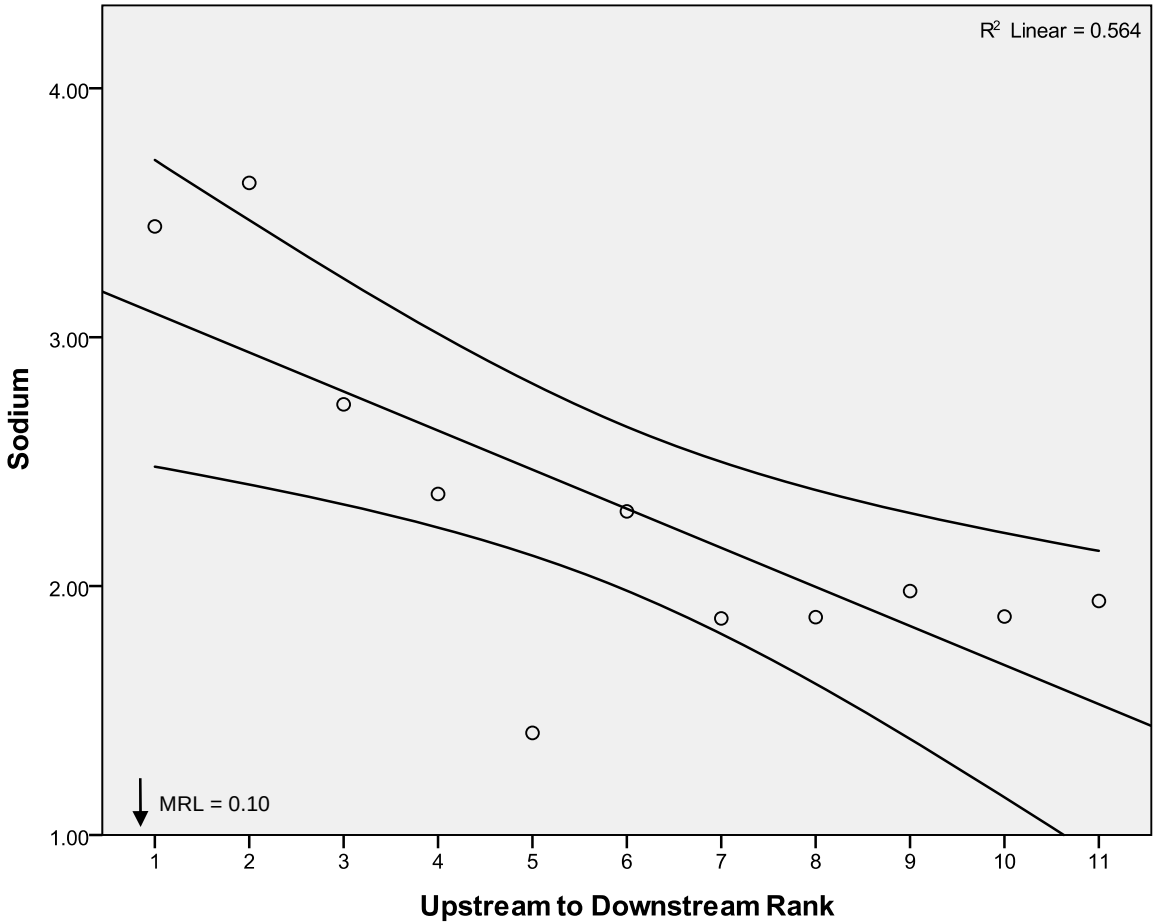
Median concentrations include only detected values.

Regression coefficient (R^2) value corresponds to best fit line.

Confidence intervals on the mean are represented by the outer lines.

MRL = method reporting limit.

SOUTH FORK KOKTULI RIVER



Location [a]	Rank [b]

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in standard pH units.

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

MRL = method reporting limit.

Notes:

Median analyte concentrations for each month are presented in milligrams per liter (mg/L).

Median concentrations include only detected values.

Only sample locations with data from at least two months, and only months with data from at least one sample location, are depicted on the graphs.

Each sampling station is represented by a unique color on the graph – symbols represent individual sampling events and lines indicate the trends between sampling events.

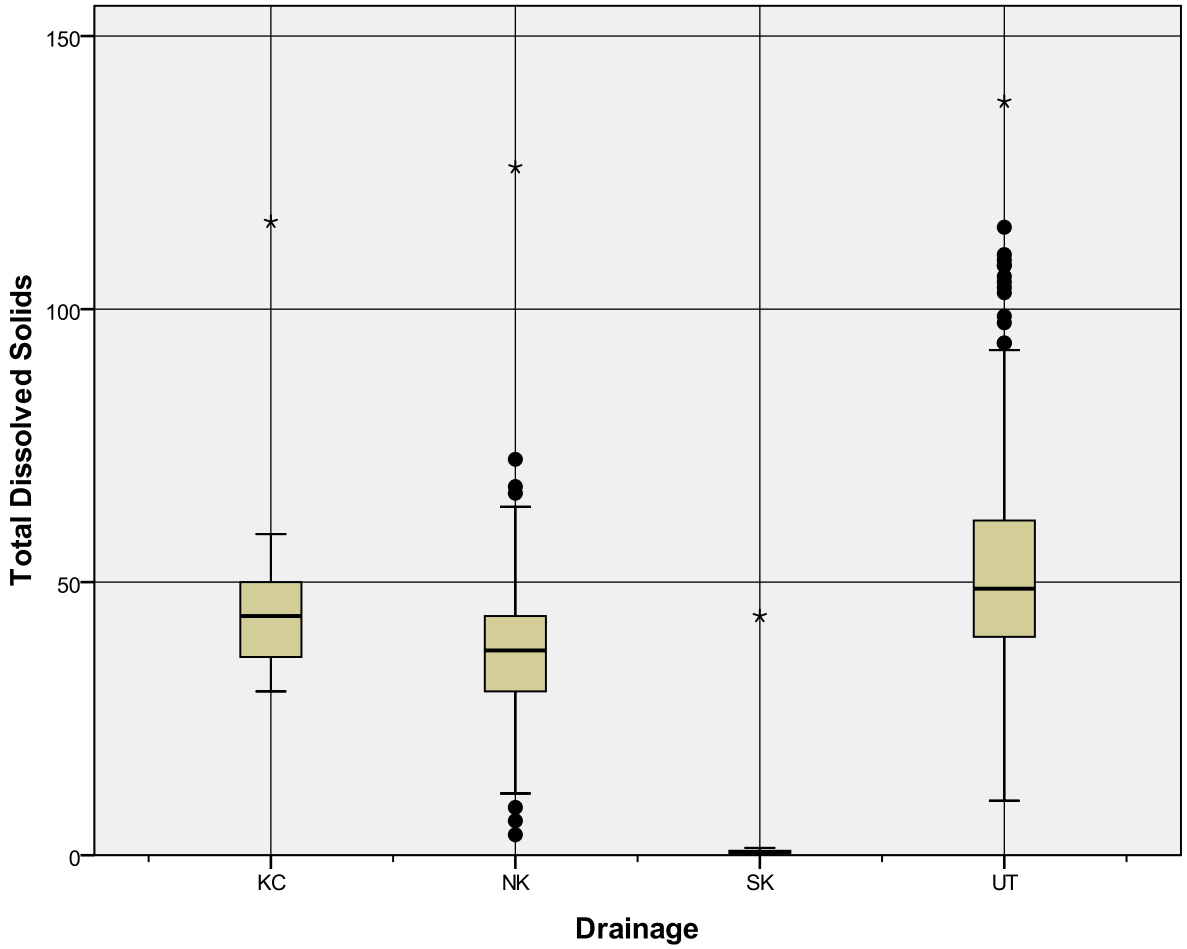
APPENDIX 9.1G

Box and Whisker Plots for Naturally Occurring Constituents in River and Creek Surface Water Mine Study Area 2004-2008



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

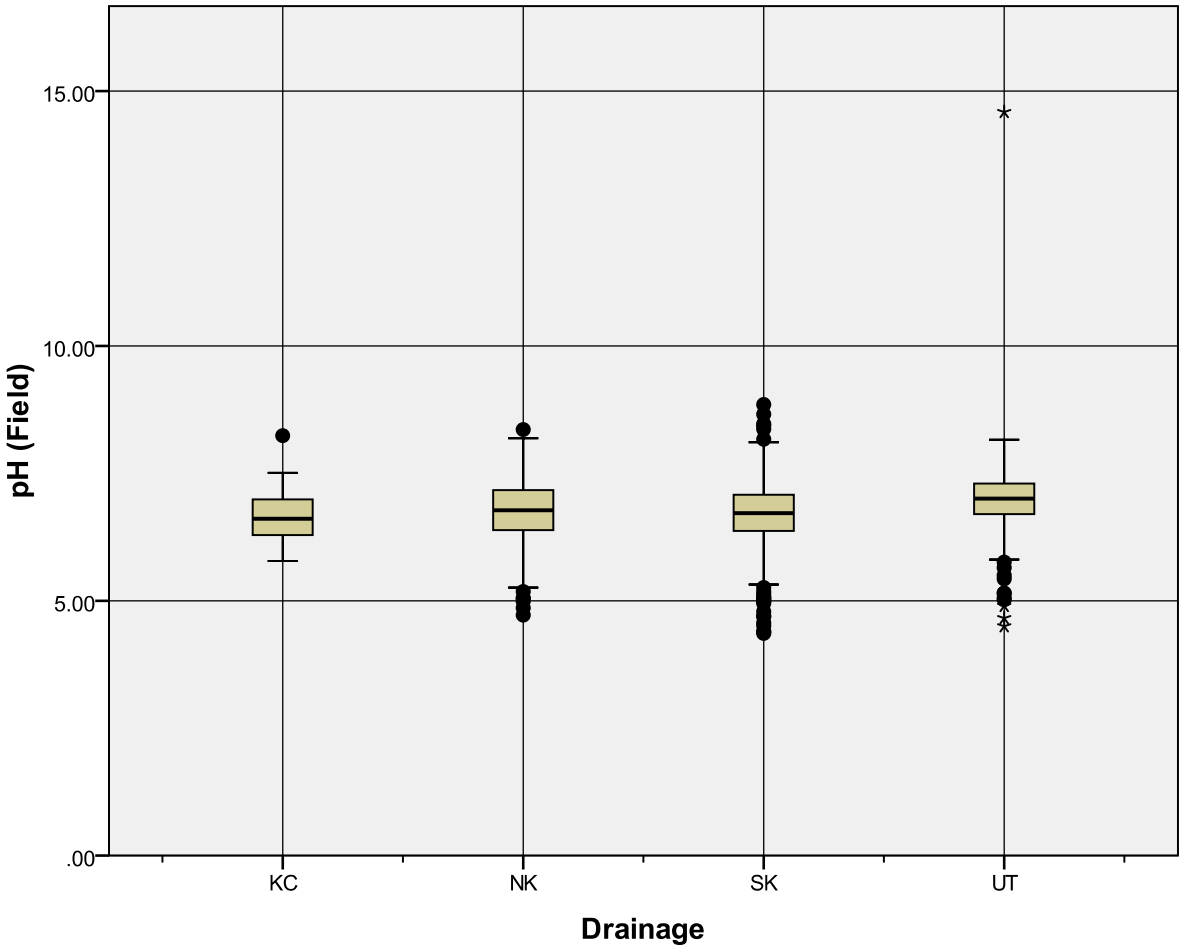
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.

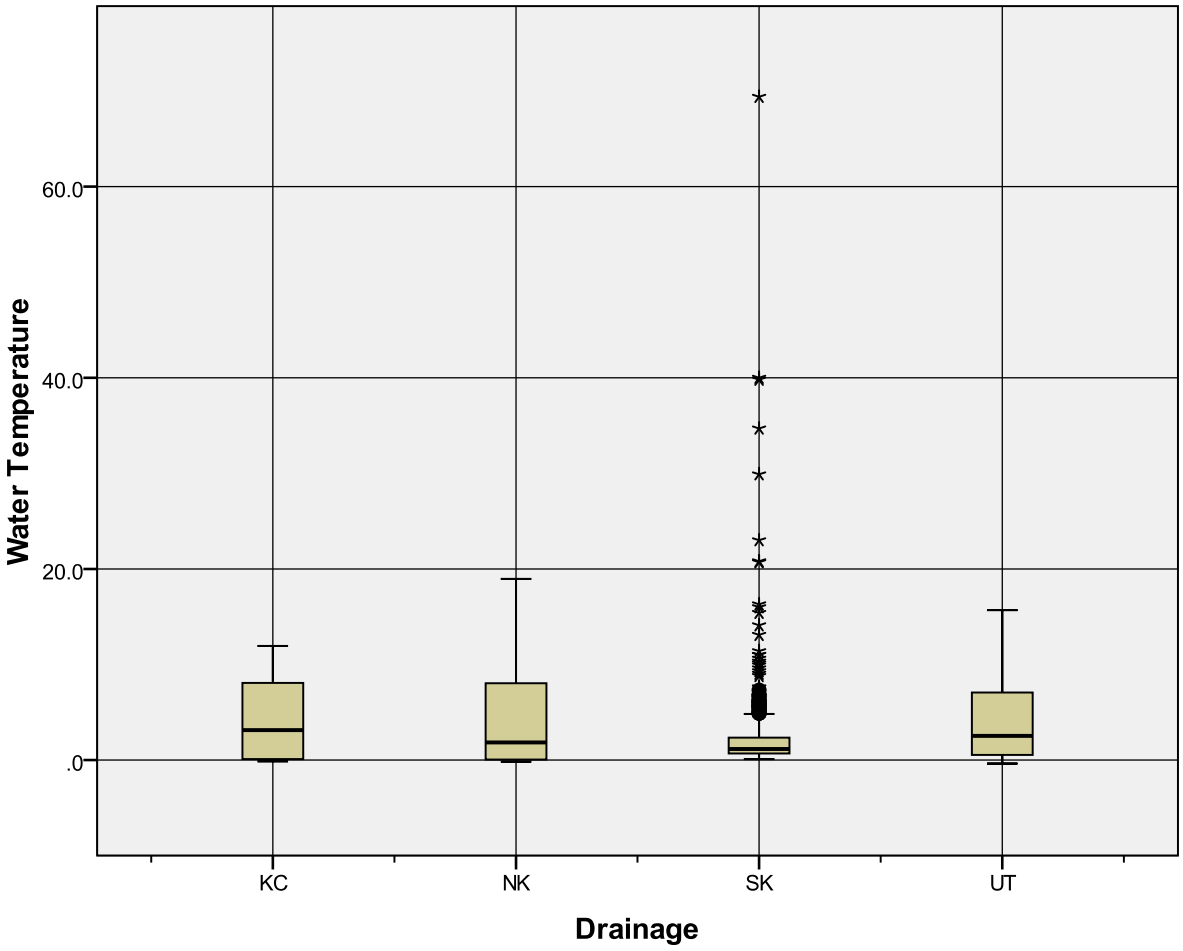


Notes:
Values are in standard pH units.
Only detected values are shown.
KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in degrees Celsius.

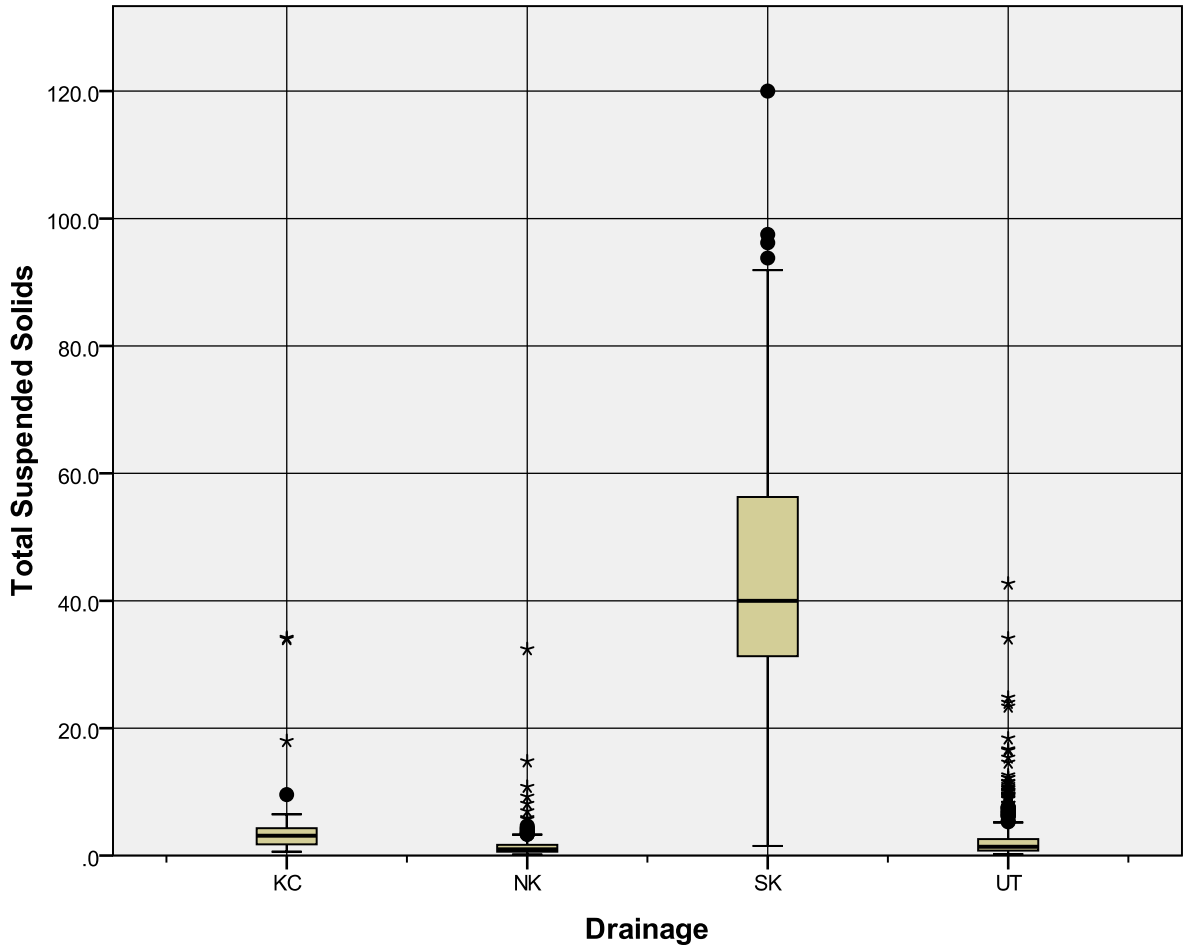
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

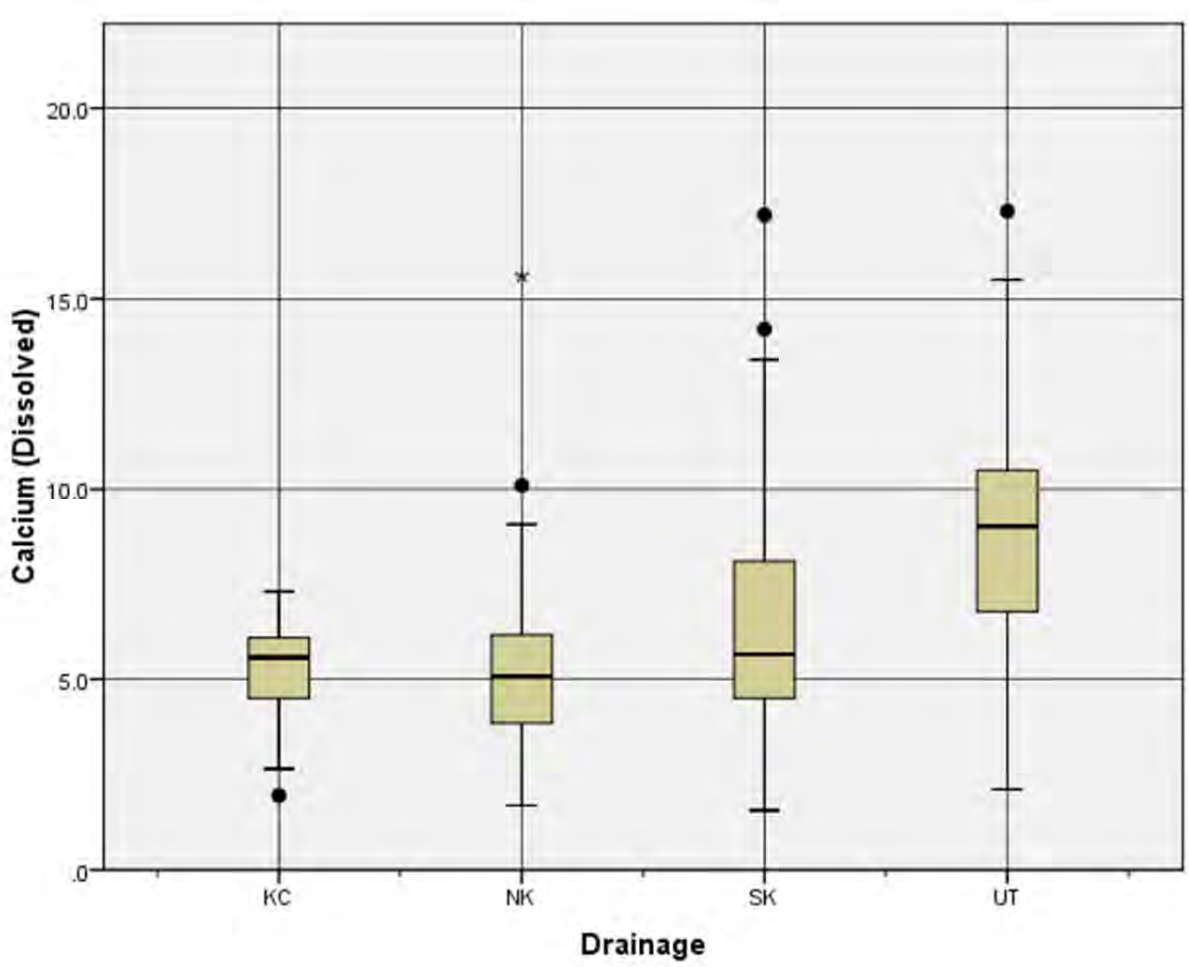
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

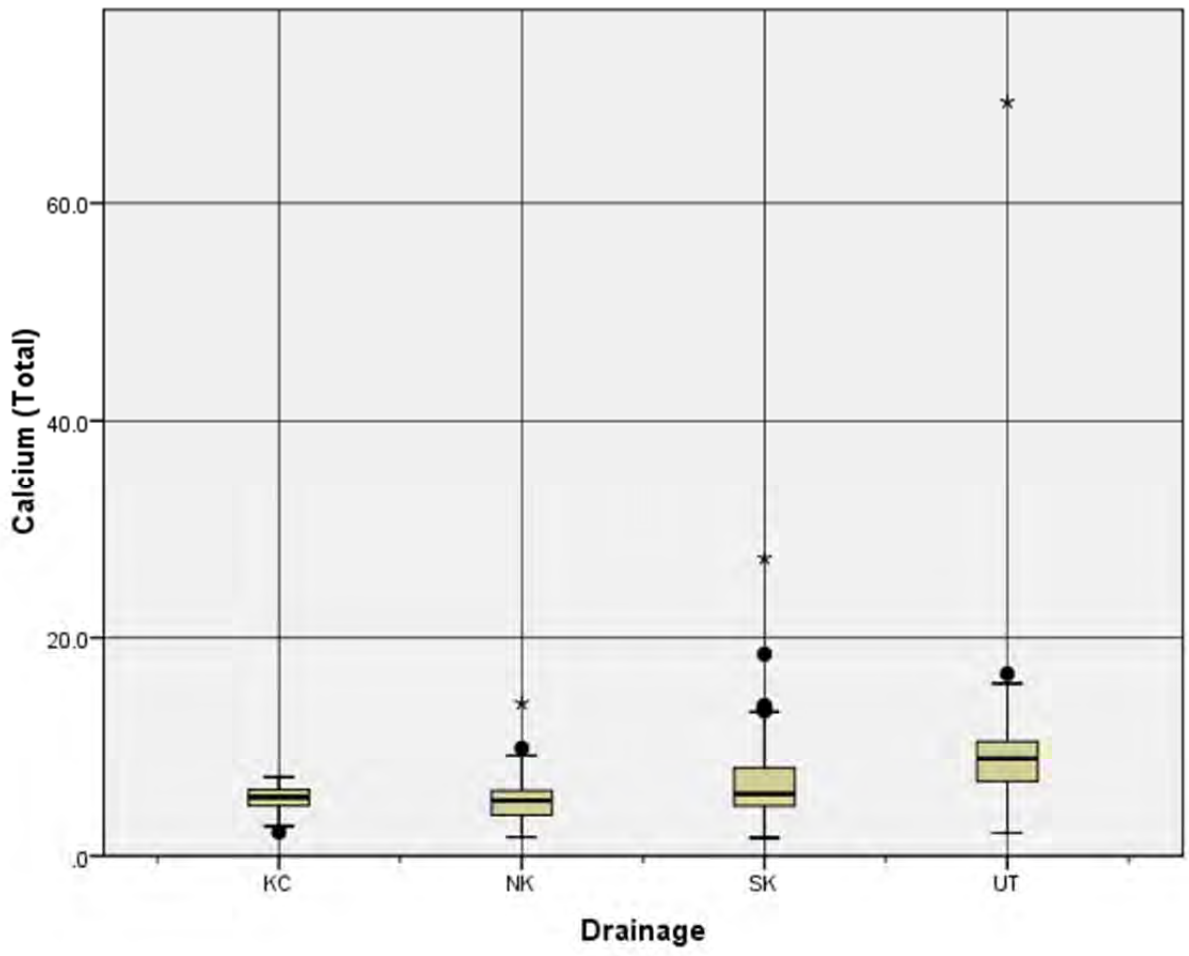
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

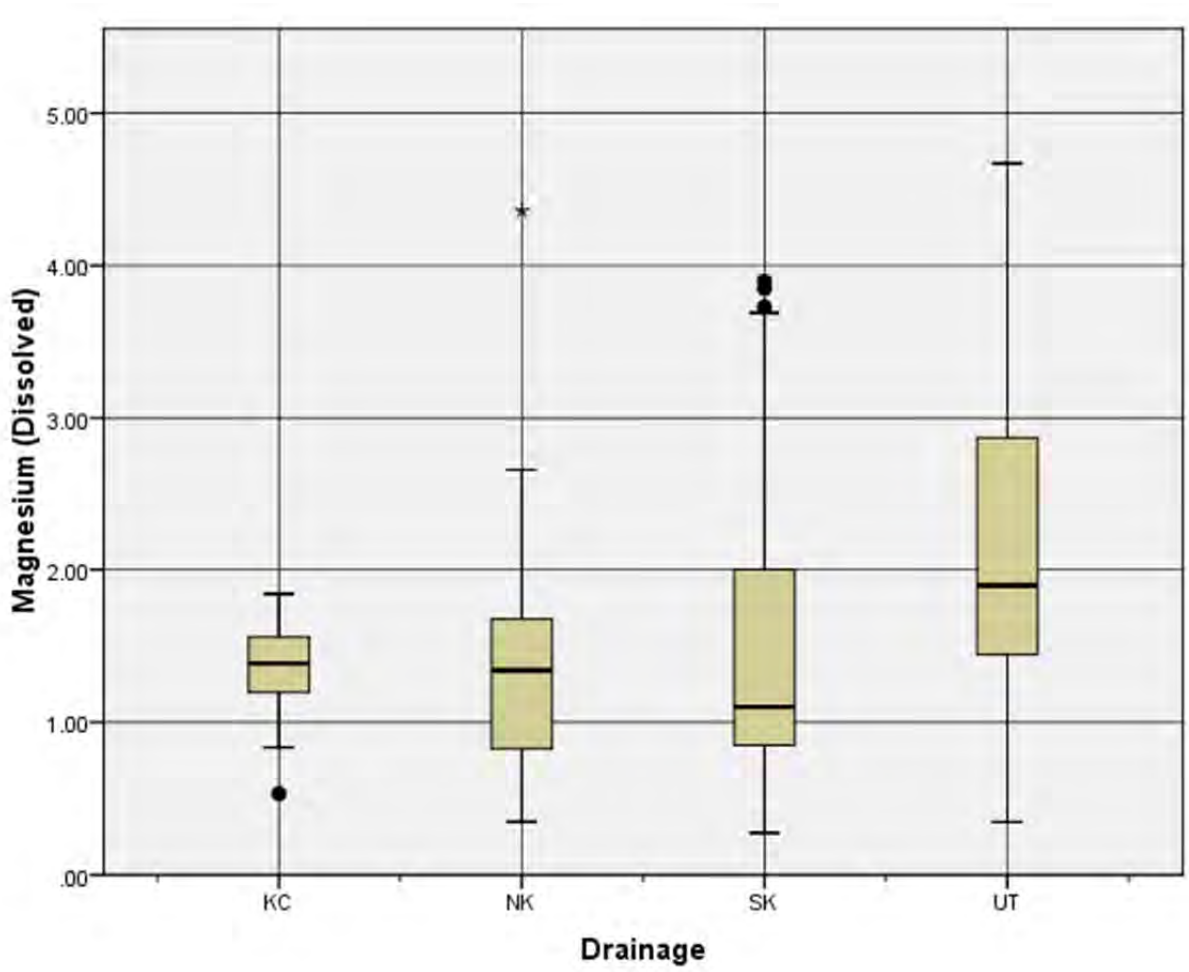
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

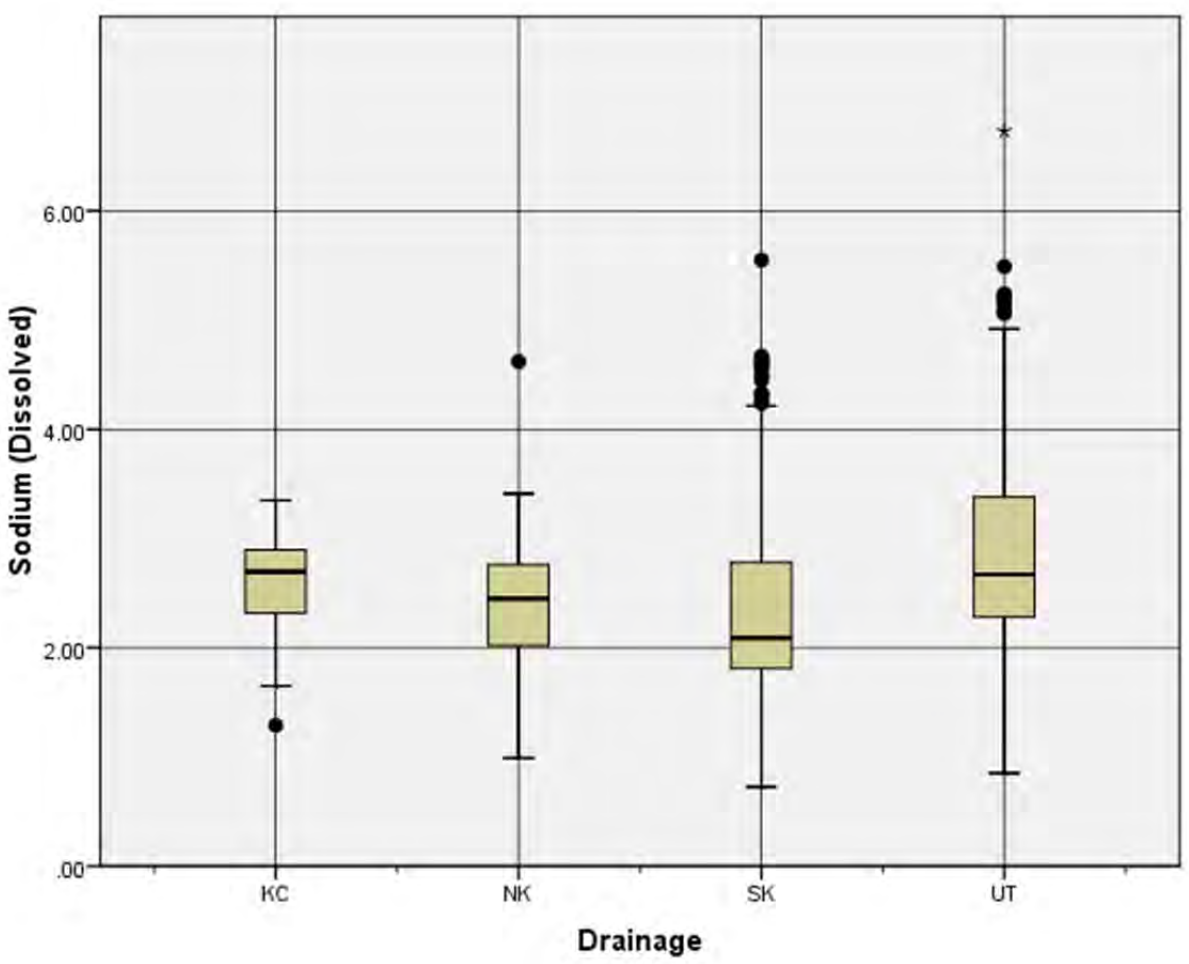
KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

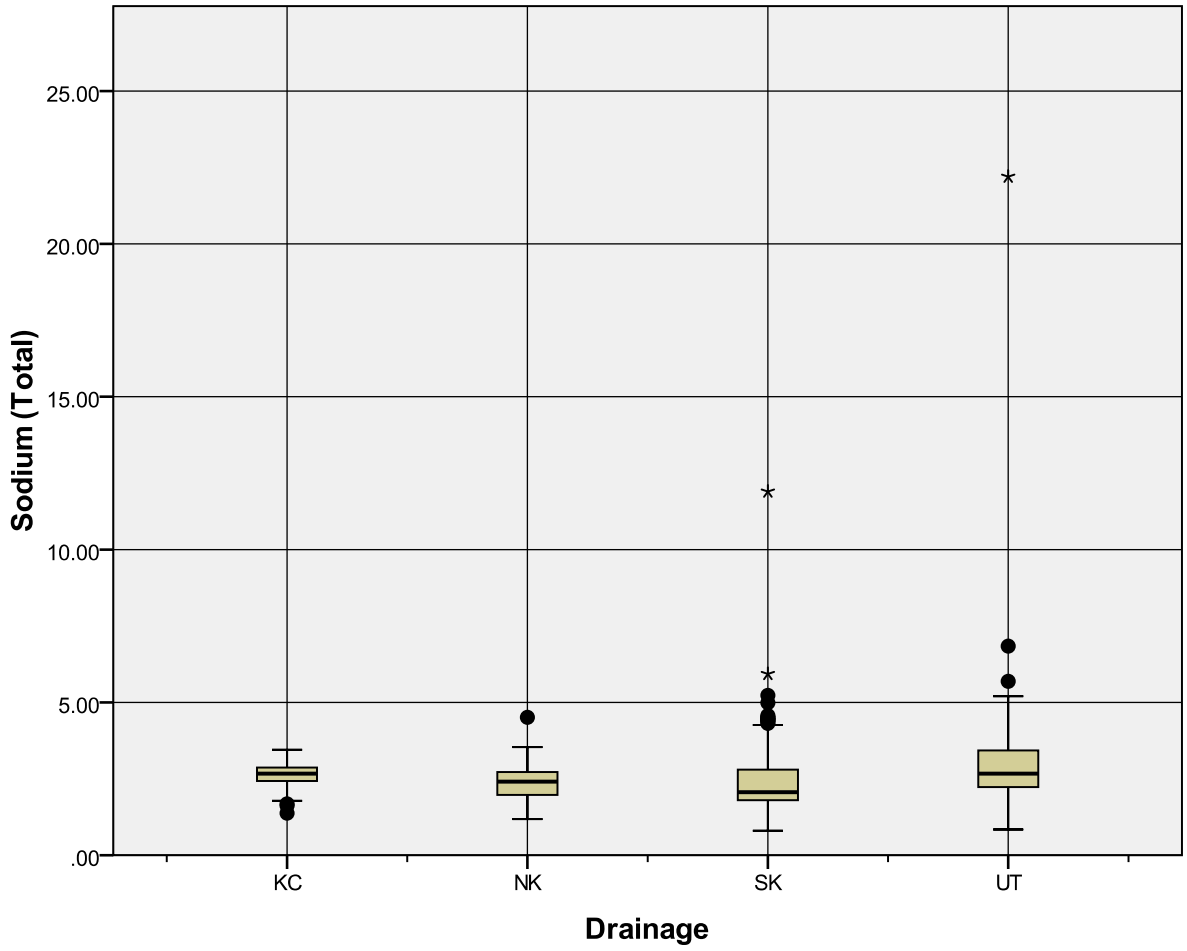
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

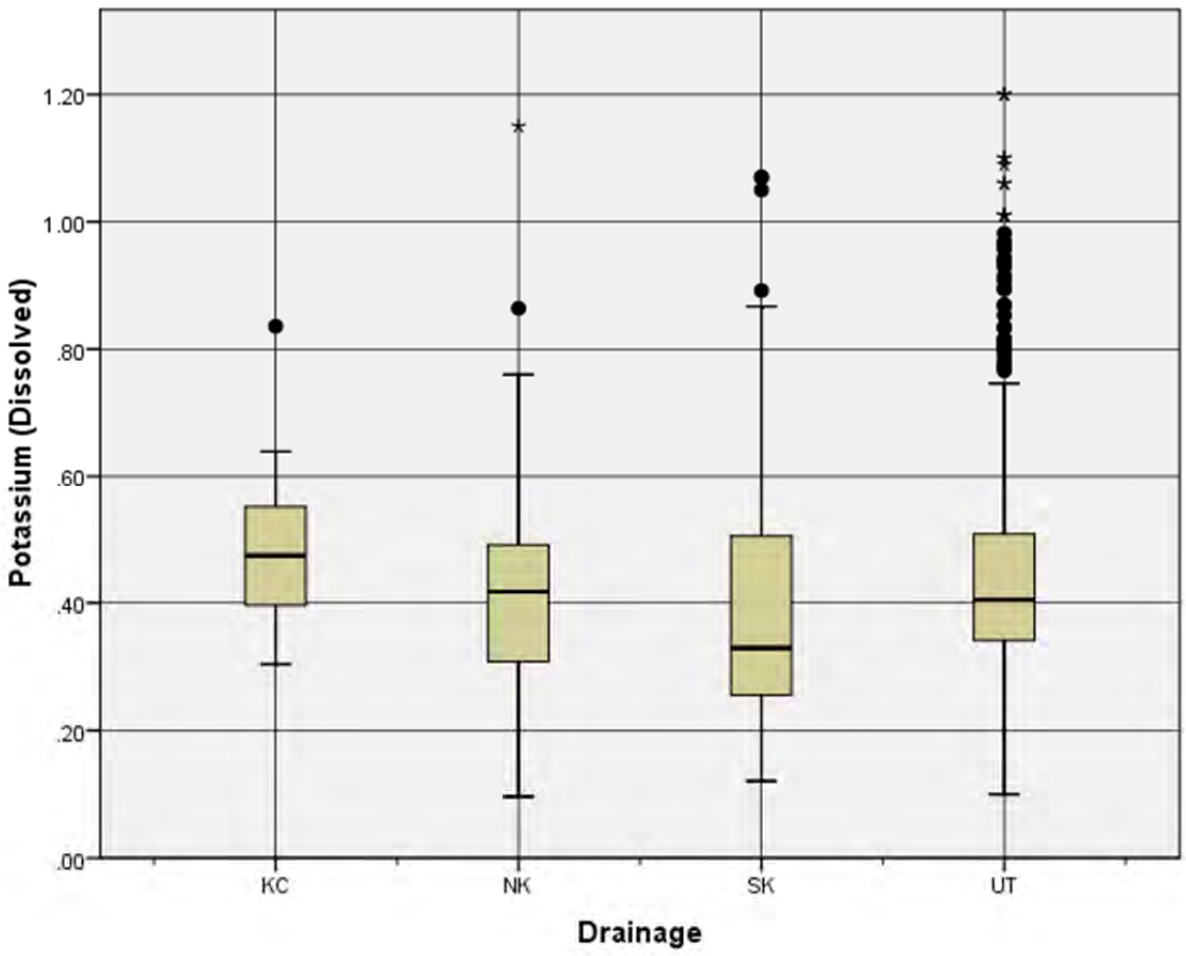
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

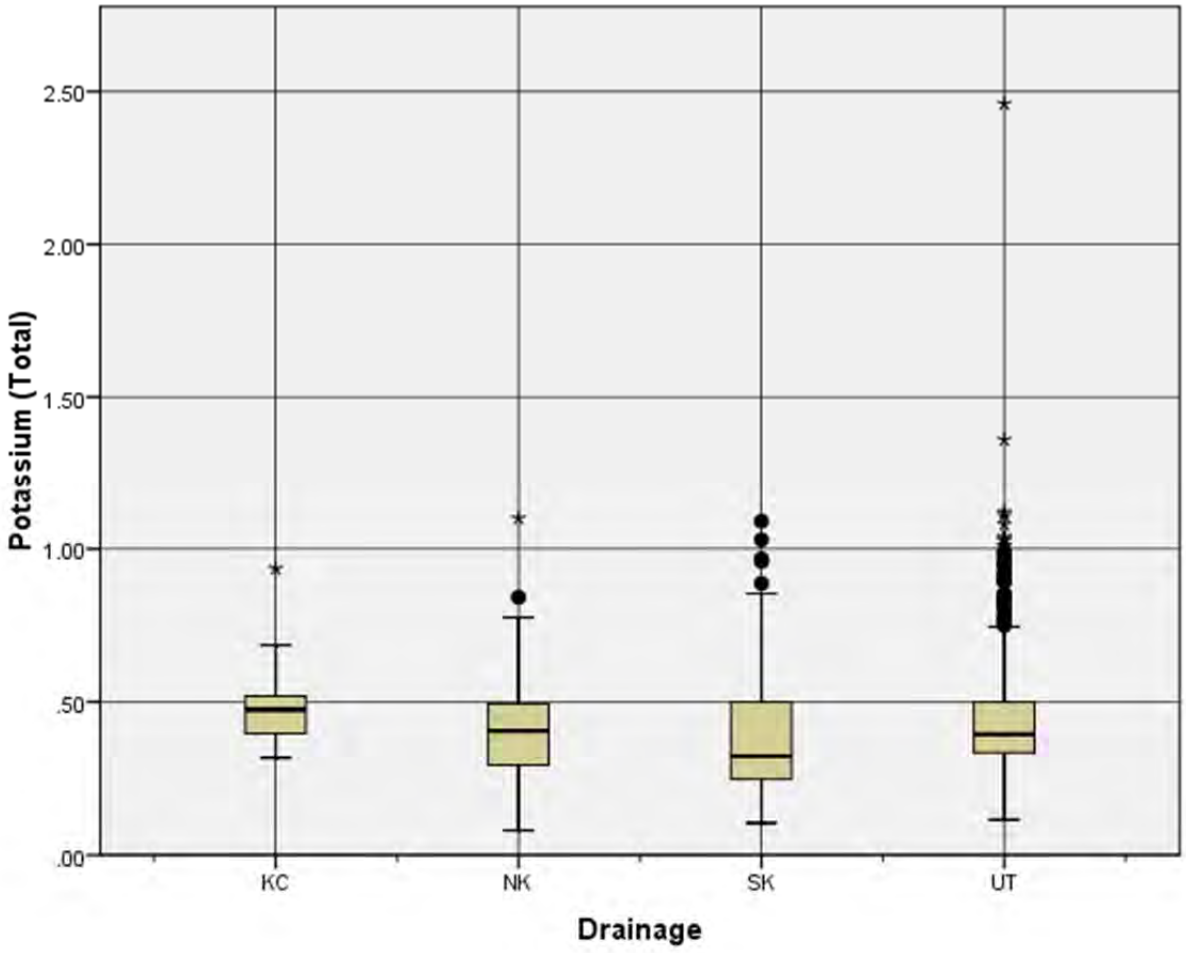
Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

Only detected values are shown.

KC = Kaskanak Creek, NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

Key:
Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:
(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.

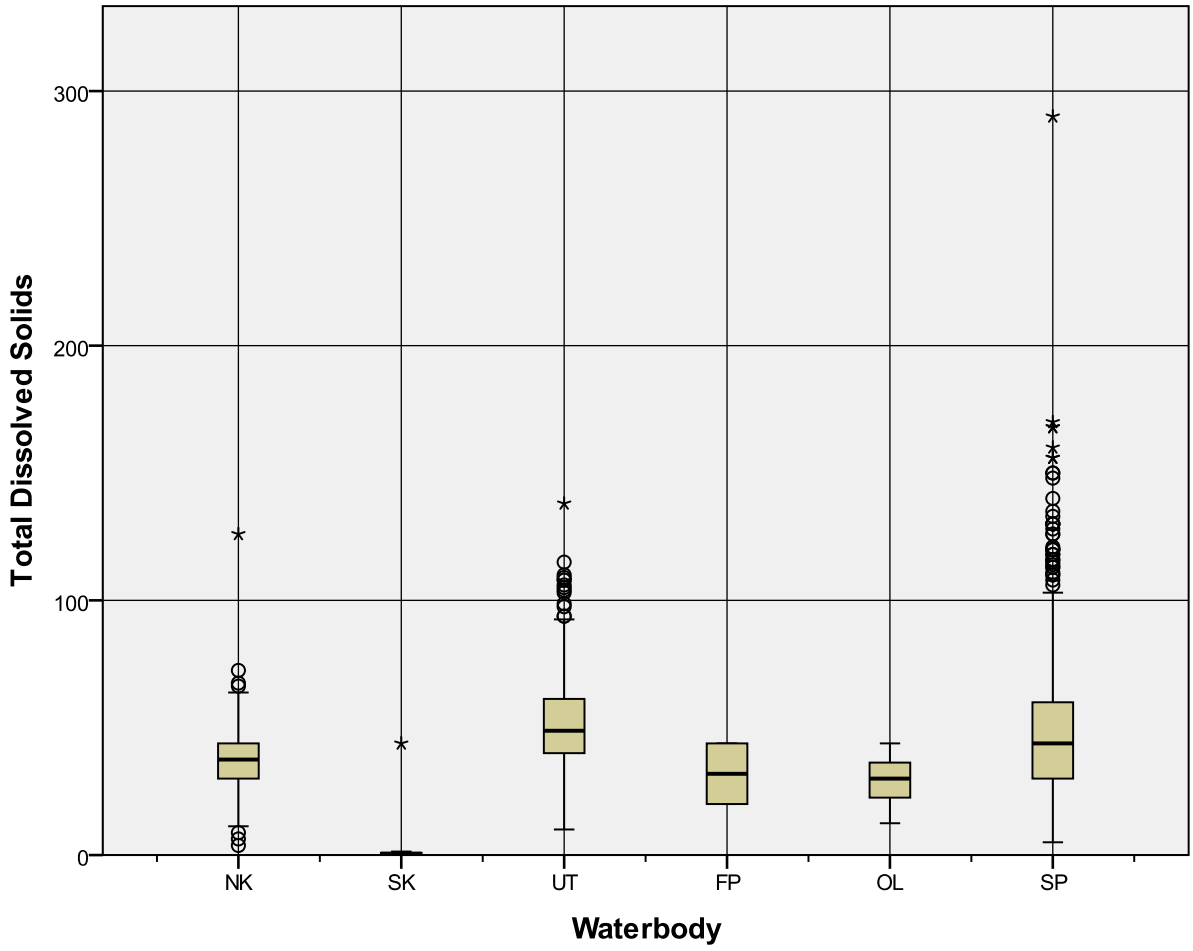
APPENDIX 9.1K

Box and Whisker Plots for Lakes and Seeps, Mine Study Area 2004-2008



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

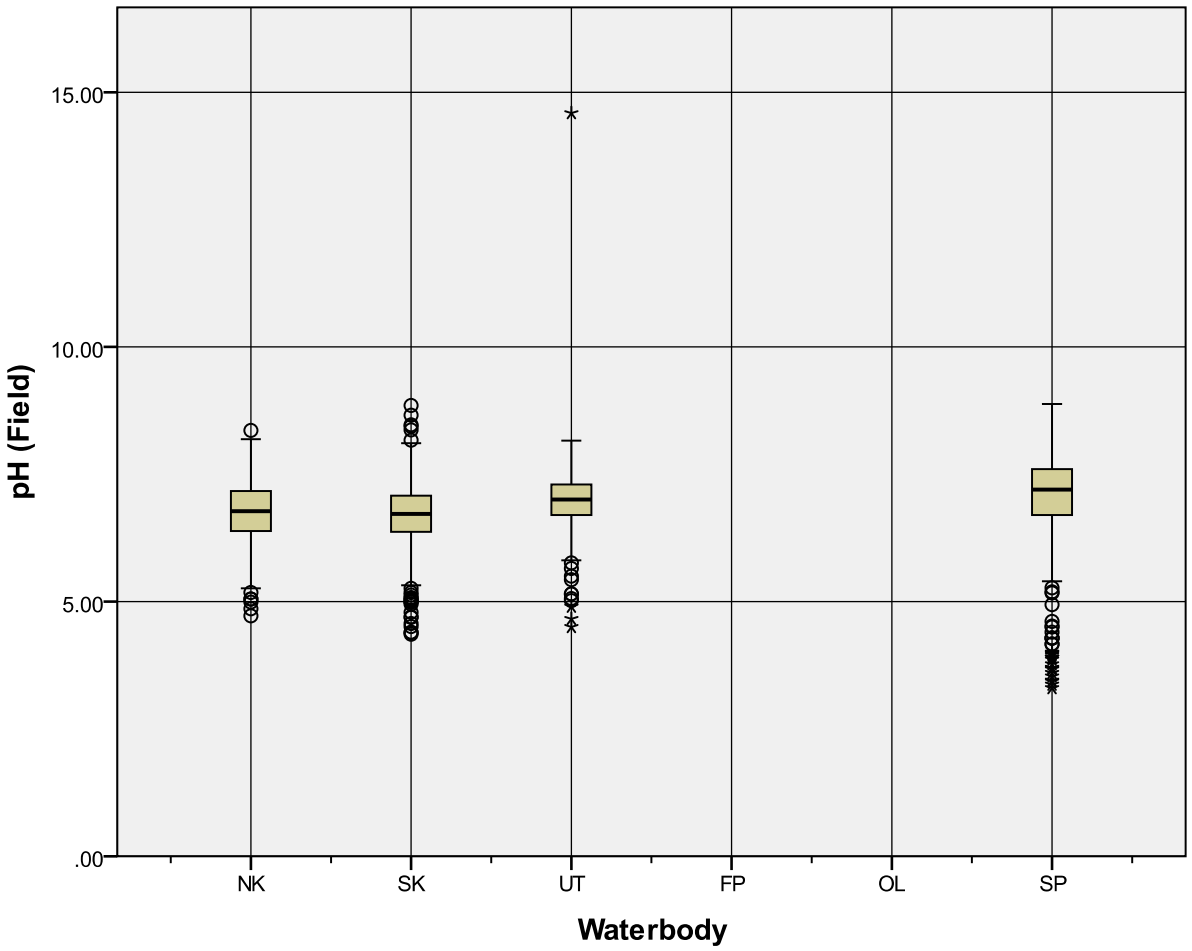
Only detected values are shown.

NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik, FP = Frying Pan Lake, OL = Other Lakes, SP = Seeps.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Values are in standard pH units.

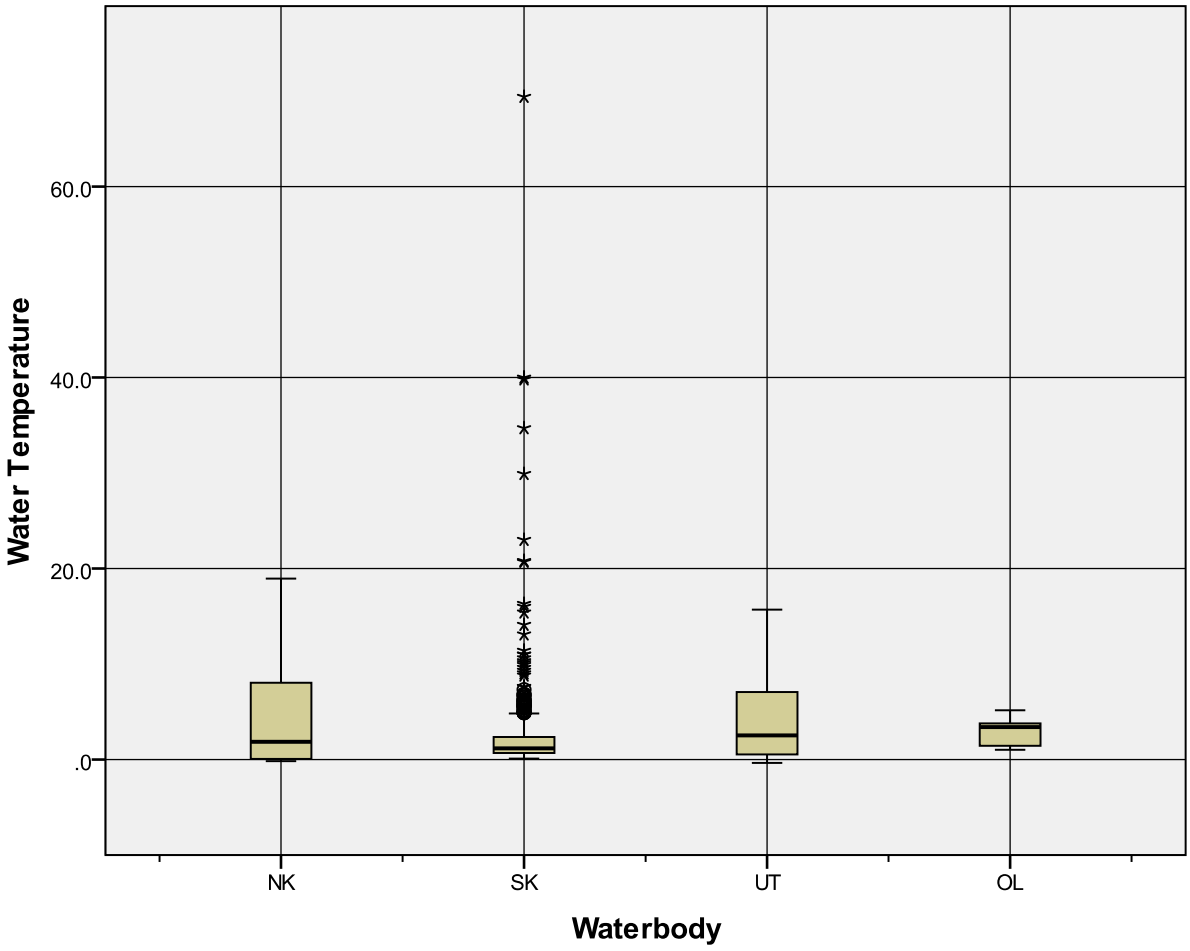
Only detected values are shown.

NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik, FP = Frying Pan Lake, OL = Other Lakes, SP = Seeps.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in degrees Celsius.

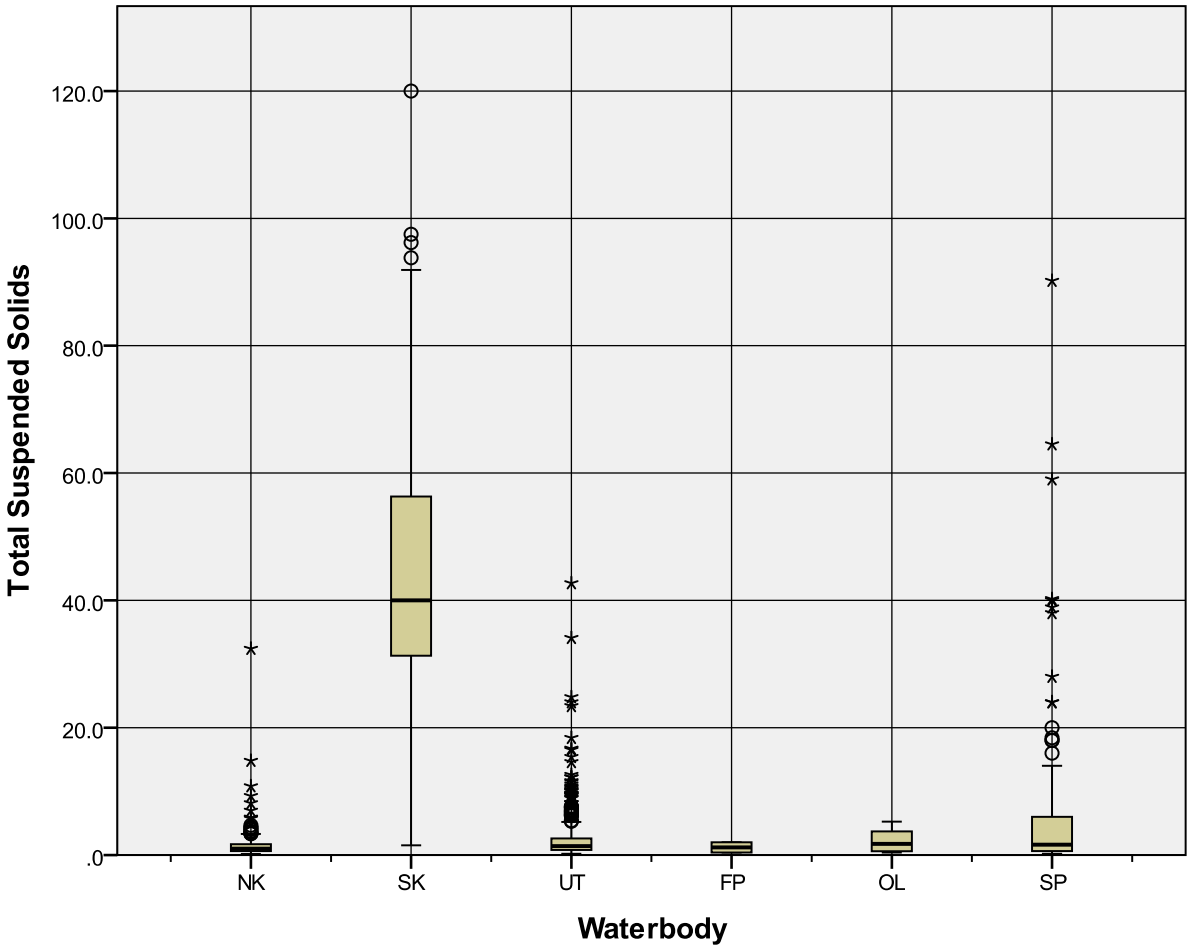
Only detected values are shown.

NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik, FP = Frying Pan Lake, OL = Other Lakes, SP = Seeps.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

Only detected values are shown.

NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik, FP = Frying Pan Lake, OL = Other Lakes, SP = Seeps.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.

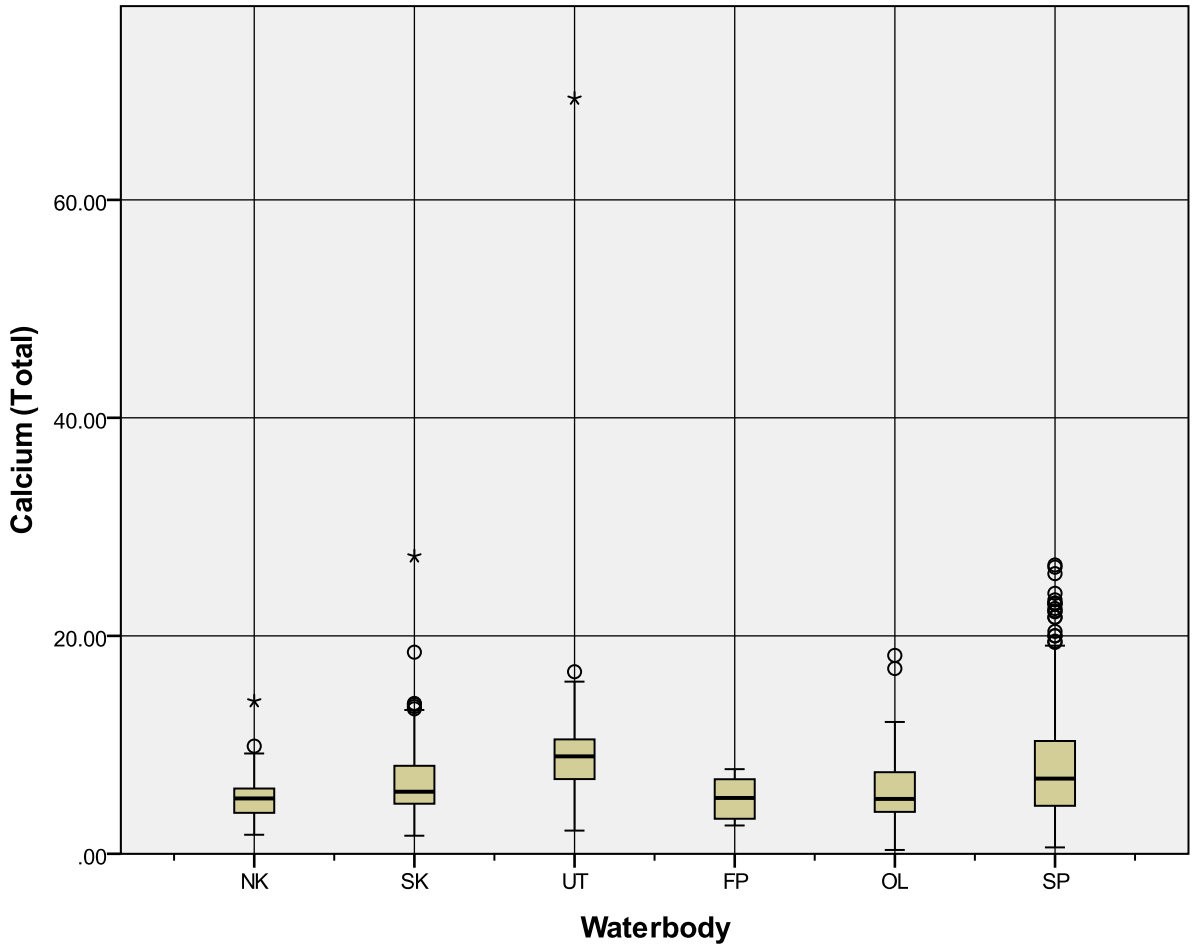
Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

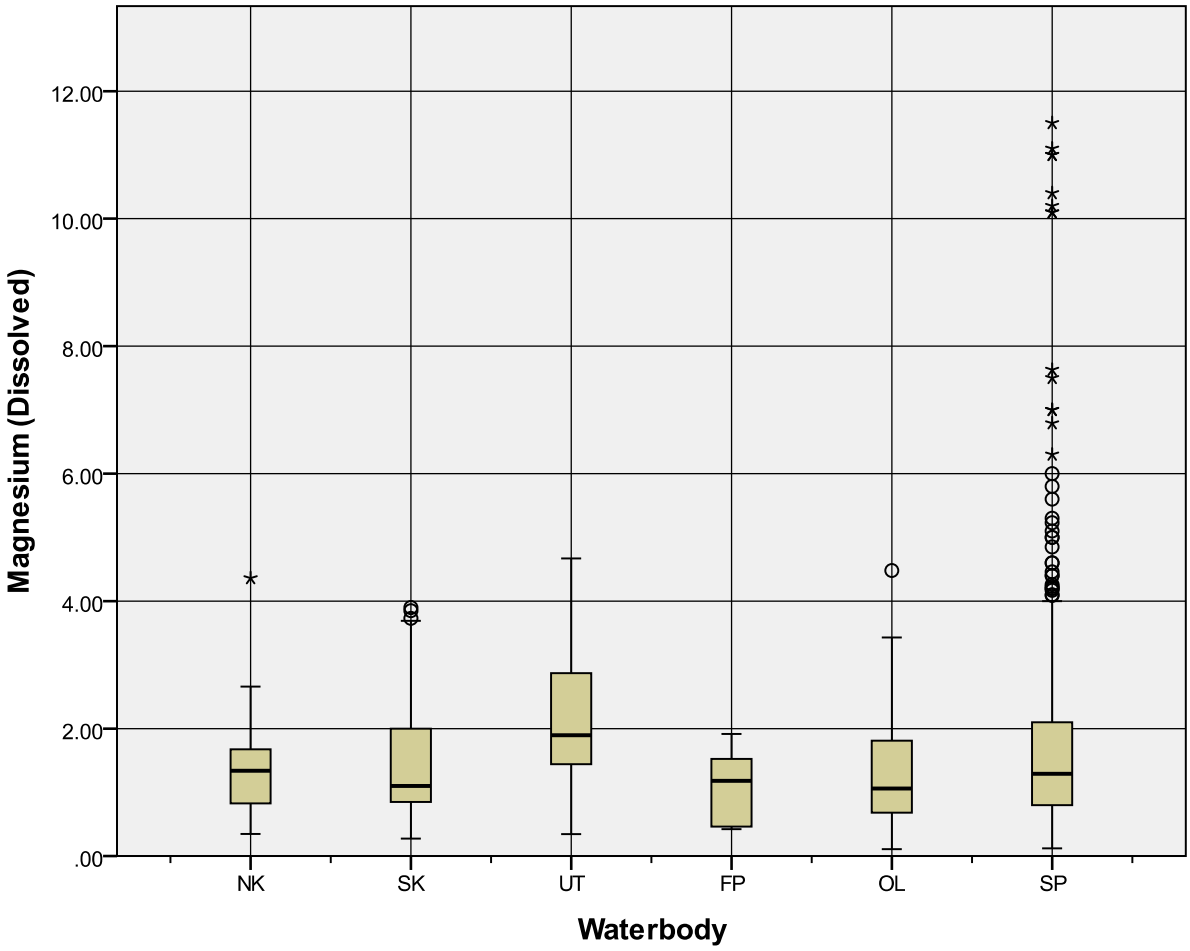
Only detected values are shown.

NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik, FP = Frying Pan Lake, OL = Other Lakes, SP = Seeps.

The length of the box represents the interquartile range of the analyte and contains 50 percent of the results.

The line inside the box represents the median value, and the smallest and largest results are represented by the length of the lines protruding from the box ends.

Outliers are represented by circles, and extreme outliers are represented by asterisks.



Notes:

Analyte concentrations are in milligrams per liter (mg/L).

Only detected values are shown.

NK = North Koktuli, SK = South Koktuli, UT = Upper Talarik, FP = Frying Pan Lake, OL = Other Lakes, SP = Seeps.

Key:
Bold Results = Parameter undetected by test, value shown is 1/2 MDL or 1/2 MRL.
If result was not detected at the lab MDL, the value shown is 1/2 MDL.
If result was validation flagged U or UJ, the value shown is 1/2 MRL.
Green Results = Estimated result reported by laboratory below reporting limit (MRL).
Red Results = Result exceed applicable Chronic Aquatic Life Criteria and/or Drinking Water Standards.
MDL = Method Detection Limit.
MRL = Method Reporting Limit.
NA = Not Applicable.
CALC = ADEC Chronic Aquatic Life Criteria
DWS = Drinking Water Standards -18 AAC 70, Water Quality Standards, under fresh water uses, (6)(A)(i) and (6)(C).
ADEC = Alaska Department of Environmental Conservation
EPA = Environmental Protection Agency
WAD Cyanide = Weak Acid Dissociable Cyanide
mg/L = Milligrams per Litre (Parts per Pillion)
µg/L = Micrograms per Litre (Parts per Billion)

Footnotes:
(1) CALC come from the ADEC Alaska Water Quality Criteria Manual – Table III and from the ADEC Water Quality Standards for Fresh Water Uses under use (C).
(2) DWS come from the ADEC Alaska Water Quality Criteria Manual – Table I, the ADEC Water Quality Standards under use (A)(i), and EPA Primary Drinking Water Standards.
(3) Total Ammonia CALC limit dependent on calculated upper 95th percentile of temperature and pH.
(4) Cadmium, Chromium III, Copper, Lead, Nickel and Zinc CALC limits are preliminary estimates and are dependent on Hardness lowest 5th percentile.
(5) Criterion given is for free cyanide. ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.
(6) Criterion given is the more stringent of those avalable for chromium III and chromium VI. Analysis is of total chromium.
(7) The Criterion given for total mercury concentration is based on the Alaska Water Quality Criteria Manual for Toxic and Other Deleterious Organic and Inorganic Substances, 2002.
(8) Criterion given is an acute criterion, rather than a chronic criterion. No chronic aquatic life criterion has been established for silver.
(9) Precision displayed in values may be less than actual where unit conversions were necessary, esp. Hg, Si, B.

9.2. Groundwater—Mine

9.2.1. Introduction

This section discusses the groundwater sampling results from the beginning of the sampling program in September 2004 up to December 2008. The data were analyzed to identify spatial and temporal variations, and were also compared with water quality criteria to provide a context for groundwater quality. The objective of the following discussion is to report on the baseline groundwater sampling and analysis completed up to and including December 2008, and the current understanding of groundwater chemistry based on this sampling.

9.2.2. Study Objectives

The objectives of the baseline groundwater sampling program include the following:

- Characterize current groundwater resources.
- Support assessments of aquatic and fish resources, and wetlands habitat.

This portion of the water quality study provides groundwater quality data in the vicinity of the Pebble Deposit. Monitoring wells have been installed over large areas to characterize the groundwater regime in a broad area.

The groundwater quality study is interfaced with concurrent baseline studies of surface water hydrology and surface water quality. The surface water quality data are discussed in Section 9.1.

9.2.3. Scope of Work

The scope of work for the groundwater program included the following tasks:

- Measurement of field parameters (temperature, dissolved oxygen [DO], pH, and electrical conductivity) for all sampled wells (Appendix 9.2A).
- Collection of quarterly samples from 39 groundwater monitoring wells from September 2004 to December 2008 (551 samples).
- Collection of a single set of seven samples from drill hole DH-8417 to a depth of about 4000 feet.
- Analysis (Appendix 9.2B) and interpretation (Appendix 9.2C, Appendix 9.2D, Appendix 9.2E, Appendix 9.2F, Appendix 9.2G, Appendix 9.2H, Appendix 9.2I) of the samples that were collected.

The samples were collected according to the protocol laid out in the Consolidated Study Plan, the Field Sampling Plan, and the Quality Assurance Project Plan (QAPP) for Pebble Project (Appendix E, F, and G, respectively, of this environmental baseline document [EBD]). The September 2004 samples were collected by CH2M Hill Inc., and the October 2004 samples were collected by Bristol Environmental and Engineering Services Corp. All other samples were collected by SLR Alaska (SLR).

9.2.4. Methods

9.2.4.1. Site Selection

Groundwater-sampling sites (Figure 9.2-1) were selected to collect data in the general deposit area. Most of these sampling locations have nested wells in separate boreholes with screens completed at different depths (Table 9.2-1), which allow groundwater to be collected from various depths within the groundwater system and facilitates interpretation of three-dimensional groundwater flowpaths. As the site investigations expanded each year, the number of wells regularly increased from 21 wells at 10 locations in 2004 to 39 wells at 20 locations in 2008. By 2008, 14 of the sampled wells were completed in bedrock and 25 were completed in overburden. In addition, deep bedrock drillhole DH-8417 (4,050 feet) was sampled once during drilling in 2008 at seven depth intervals.

9.2.4.2. Well Naming Convention

Examples of names for monitoring wells include the following:

- PQ4
- DH-8417
- SRK3
- MW-5S
- P-06-37D

The prefix in the name indicates the program from which the installation originated, as follows:

- PQ: drilling associated with collecting rock core samples for acid-base accounting;
- DH: an exploration drill hole;
- KP and SRK: geotechnical drilling;
- MW and P: hydrogeology program.

In some cases, the year of installation is indicated in the name immediately after the prefix, as in well P-06-37D, which was installed in 2006. The number in the drill hole name is a sequential number that originated from the respective program. For example, well MW-5S was the fifth installation in the series of “MW” installations. Finally, monitoring wells were installed at multiple depths at a given location in many cases. The suffixes used for indicating relative depth were as follows:

- S: the most shallow installation;
- M: the installation at an intermediate depth, if one was installed;
- D: the deepest installation.

Each suffix indicates the relative depth of the installation at a particular site but does not indicate the absolute depth.

9.2.4.3. Groundwater Sampling Methods

Groundwater sampling protocols identified and discussed in the Consolidated Study Plan (Appendix F of this EBD) were used to collect the groundwater samples. Sampling events were timed to coincide with (1) high groundwater levels in the spring and early fall, (2) low groundwater levels in summer and winter, and (3) the surface water chemistry sampling program. Before sampling at each well, the depth to groundwater was measured using an electric well probe. Prior to installing the sampling port, the depth to groundwater was referenced to the top of the polyvinyl chloride (PVC) casing. After the sample port was installed, the depth to water was referenced to the top of the sampling port. A dedicated Fultz® electric submersible pump was used for sampling. This pump was used to purge groundwater from the well at rates of less than 0.5 liters (L) per minute (Lpm). During well purging, water quality parameters were measured using a Horiba® model U-22 multi-meter (2004 sampling) or YSI Model 556 multi-meter (2005 through 2008 sampling). Parameters measured included pH, conductivity, DO, temperature, and oxidation-reduction potential. After the minimum purge volume was purged, the sampler waited until the field parameter readings stabilized before collecting the sample. The meter was calibrated daily before use, and calibration specifics were recorded in field reports. At the end of purging, the purge water was tested for ferrous iron using a Hach® model 890 field kit during the early part of the sampling program, but was discontinued because ferrous iron was not detected. Samples were collected from the tubing discharge and placed directly into laboratory-prepared sample containers.

Water samples were collected for analysis of major ions, dissolved solids, nutrients (nitrogen and phosphorous), tritium, and total and dissolved metals. The field collection and filtering equipment used was made from Teflon, glass, or stainless steel to prevent sample contamination and to minimize analyte losses through adsorption. All sampling equipment was cleaned prior to use at each sampling site with a non-phosphate laboratory detergent and rinsed with distilled water. The submersible sampling pumps and filters were dedicated to individual wells. Triplicate samples were collected at more than 10 percent of the sampling sites. Field equipment rinse blanks were rarely required, because the sampling equipment was generally dedicated to the respective well. In those occasional instances, when a pump had to be borrowed from another well due to equipment malfunction, a rinse blank was collected and submitted to the laboratory.

Dissolved-metals samples were filtered in the field at the time of sampling through in-line, high-capacity 0.45-micrometer disposable filters. After the chain-of-custody forms were completed and the bottles were packed in coolers with gel-ice packs, they were shipped to SGS/CTE Environmental Services in Anchorage, Alaska. The quality assurance (QA) samples were sent to Columbia Analytical Services in Kelso, Washington. Table 9.0-1 lists the parameters that were analyzed by the project laboratories and their respective analytical methods.

In the deep bedrock well (DH-8417), groundwater samples were collected by airlift pumping from nine depth intervals while the hole was being drilled. To isolate depth intervals for pumping tests, two approaches were used. At shallower depths, the hole was cemented after the pumping was complete to seal the formation, then the hole was advanced by drilling through the cement. At greater depths, where the rock was more competent, the lower interval of the hole was isolated from the upper part by an inflatable packer, and water was pumped from the lower interval. Near the end of airlifting of each interval, a sample was collected. The sample concentrations may have been affected by the aeration associated with airlifting and by the presence of cement.

9.2.4.4. Data Interpretation Methods

The groundwater data were evaluated using several techniques, as described in the following paragraphs.

Logarithmic Scales

Data were often plotted on a logarithmic scale to make the low concentrations easier to distinguish. The use of logarithmic scales is explained in Chapter 9.0.

Percentile Distribution of Concentrations

The percentile distribution of concentrations was interpreted using box and whisker diagrams so that the full dataset could be assessed in a single plot. In respective diagrams, the data were grouped by both watershed and lithology so that differences and similarities would be evident. Similarly, the groundwater composition was assessed by plotting the data on Piper diagrams (Piper, 1944). This diagram allows the proportional content of each constituent to be assessed independently of absolute concentrations. The use of Piper plots is explained in Chapter 9.0.

Spatial Variation

Spatial variation of groundwater composition and concentration was assessed by plotting Stiff diagrams positioned at the respective well locations on the study area map. The overburden and bedrock wells were plotted in distinct colors so that similarities and differences could be assessed. These plots provided an easy means of simultaneously assessing sample composition and total dissolved solids (TDS) for each sampling snapshot.

Comparison with Water Quality Criteria

Groundwater concentrations were also compared with surface water criteria to provide context for the data, as described in the introduction to Chapter 9.

Temporal Trends

The data were analyzed in two steps to determine temporal trends. In the first step, the Mann Kendall statistical test was applied (Gibbons, 1994). This test calculates and compares the number of positive and negative slopes of all lines connecting the points in a time series diagram. If the number of positive slopes is statistically greater than the negative slopes, the hypothesis of an increasing trend is accepted. Conversely, if the number of negative slopes is statistically greater than the number of positive slopes, the hypothesis of a decreasing trend is accepted. This methodology had the advantage of processing a large number of station-constituent combinations and quickly providing a list of trending constituents at each station. Only datasets with more than 50 percent detects and a minimum of four data points were analyzed for trending. In the second step, all candidates where the Mann Kendall test calculated a probability of an increasing or decreasing trend greater than 95 percent were plotted in a time series diagram and the trend was visually rejected or confirmed (Appendix 9.2I). Undetected concentrations were plotted as half of the detection limit. Out of 821 parameter-well combinations, 209 candidates of a decreasing trend and 78 candidates for an increasing trend were flagged using the Mann Kendall trend test, and these combinations were subsequently inspected visually using time series diagrams.

Constituent Correlations

Constituent correlations resulting from geochemical reactions along the groundwater flowpaths were evaluated through a two-step analysis. In the first step of this analysis, two matrices of Pearson correlation coefficients (EPA, 2000) were calculated for overburden and bedrock samples using 45 parameters. The coefficient was calculated using the formula for the Pearson coefficient (EPA, 2000):

$$r_{xy} = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{(n-1)s_x s_y}$$

Where:

x_i = concentration of parameter x in sample i.

y_i = concentration of constituent y in the same sample.

$\bar{x}$ = mean concentration of parameter x in all samples.

$\bar{y}$ = mean concentration of parameter x in all samples.

n = number of samples.

s_x = sample standard deviation for constituent x.

s_y = sample standard deviation for constituent y.

This coefficient ranges from 1 to -1, where 1 denotes a perfect proportional correlation (all points on a line with a positive slope), 0 denotes complete lack of correlation, and -1 denotes a perfect inverse correlation. The parameters included 42 chemical parameters, hydraulic conductivity, and sampling depth (Appendix 9.2H). The parameters were correlated on averaged values for each station rather than raw data to dampen the effect of data variability. Extreme concentrations that were previously flagged as outliers in the database were removed prior to averaging the data. A threshold of 0.8, which was based on the distribution of coefficient values, was used to select parameters that were potentially correlated. Correlation coefficients greater than 0.8 and less than -0.8 were then highlighted in each matrix (Appendix 9.2H).

In the second step, the highlighted parameter pairs were plotted on scatter plots to visually assess whether the parameters were actually correlated. The scatter plots were developed for elements that would be derived from minerals that were expected to be present in the aquifer of the study area. For example, calcium, magnesium, and bicarbonate were expected to correlate in the presence of carbonates. Similarly, silica and sodium were expected to correlate in the presence of sodium-feldspar. For most values that were highlighted during the first step, the scatter plot indicated that an extreme value was responsible for the high correlation coefficient and that the majority of constituents were actually not correlated.

9.2.4.5. Data Quality Checks

Ten percent of all groundwater samples were quality assurance/quality control (QA/QC) duplicates and triplicates. Laboratory data precision and reproducibility based on these samples is discussed in Appendix A, Analytical Quality Assurance/Quality Control Review. Additional quality control checks,

which were based on historical data and a comparison of field and laboratory measurements, were applied in the scope of this assessment of groundwater chemistry. The following paragraphs discuss these checks.

Comparison of Field and Laboratory Measured Electrical Conductivity

The field and laboratory measurements of conductivity were expected to be similar and, therefore, to be located close to the 1:1 line when plotted on a scatter plot (Figure 9.2-2). The dashed lines show the areas where the laboratory electrical conductivity deviated by less than 10 percent from the field conductivity. This diagram shows that the match between field and laboratory measurements was generally better at higher electrical conductivity values. A few outliers were identified, which were again verified in a time series plot of the field and laboratory measurements. The high laboratory value at PQ4 seemed to be a transcription error (missing decimal), since the value of 900 microSiemens (µS) per centimeter (cm) was 10 times higher than all other laboratory measurements and the field electrical conductivity indicated a value of 92 µS/cm. One laboratory measurement was too high for well MW-13D, and one measurement was too low for each of wells MW-12S and MW-14D. Samples from these wells were also checked for ion imbalance. The ion imbalance for well MW-12S (March 24, 2006) was greater than the data quality objective (DQO) of 5 percent. Therefore, the chemistry of this sample likely changed between the field and the laboratory. In the other two samples, one of the EC measurements was probably incorrect.

The field measurements of EC were generally more reliable, which was not necessarily expected because the EC is controlled by the concentration of TDS, which should not change in the sample bottle. In summary, although a few EC measurements were incorrectly transcribed, all but a few measurements were confirmed as reliable.

Comparison of Measured and Calculated Total Dissolved Solids

For a sample where all dissolved constituents were measured, the TDS can be calculated as the sum of all analyzed constituents and should be close to the measured TDS. When plotting the sum of measured concentrations (calculated TDS) against the measured TDS, all points will theoretically fall on the 1:1 line. Deviations from the line can have two causes:

- The measured TDS was inaccurate.
- One or several measured concentrations were inaccurate.

As shown in Figure 9.2-2, a few of the samples deviated noticeably from the 1:1 line. The dashed line above and below the 1:1 line delineates the area where the measured TDS values do not vary more than 10 percent from the calculated values. Samples where the measured and calculated TDS was much greater than 10 percent were again verified in the time series diagram. At well MW-3D, the calculated TDS was higher than the measured TDS on March 24, 2006. This difference could be explained by an anomalously high alkalinity concentration, which seemed to be also responsible for an ion imbalance greater than the DQO of 5 percent. For SRK3, the calculated TDS was consistently higher than the measured TDS, and this difference could not be explained. All values that deviated noticeably from the 1:1 were verified, and this observation was documented in the database. The plots of TDS used for interpreting groundwater chemistry used measured values in all cases.

Comparison of Measured TDS and Field Conductivity

The measured TDS was also compared to the field-measured EC (Figure 9.2-2). These parameters are expected to increase proportionally because they are both controlled by the total concentration of dissolved ions. A linear regression was calculated, which resulted in the following relationship:

TDS (mg/L) = 0.646 x EC (µS/cm)

The samples that departed the farthest from this line were the same samples that deviated in the other TDS and conductivity control plots.

In summary, only four samples out of 551, one from each of wells MW-14D, MW-5M, P-06-37M, and PQ4 were flagged as unreliable in the database as a result of the quality checks (Appendix 9.2C).

9.2.5. Results and Discussion

The following sections discuss the results of chemical analyses of the groundwater samples. The field parameters are tabulated in Appendix 9.2A, and the analytical results are tabulated in Appendix 9.2B. The discussion is organized into the following sub-sections:

- Field and Physical Parameters.
- Dissolved Major Ions.
- Nutrients.
- Dissolved Trace Elements.
- Cyanides.
- Constituent Correlations.
- Temporal Trend Analysis.
- Deep Groundwater Samples.

9.2.5.1. Field and Physical Parameters

The field and physical parameters include TDS, specific conductance, DO, temperature, oxidation-reduction potential, turbidity, and TSS. These parameters provide an overview of the general water-quality characteristics and, therefore, are discussed first before some of the more detailed analyses. The following paragraphs discuss each of these parameters in detail for all samples that were collected from September 2004 through October 2008.

Total Dissolved Solids

The TDS distribution in all watersheds is shown in Figure 9.2-3 for the overburden wells and in Figure 9.2-4 for bedrock wells. Figures 9.2-5 through 9.2-10 show the TDS distribution in the three watersheds for both overburden and bedrock wells.

Overburden: The concentrations of TDS in overburden ranged from 9 to 89 mg/L in the North Fork Koktuli River (NFK) watershed (Figure 9.2-5), from less than 3 to 500 mg/L in the South Fork Koktuli River (SFK) watershed (Figure 9.2-6), and from 11 to 212 mg/L in the Upper Talarik Creek (UT)

Watershed (Figure 9.2-7). The median concentrations in the NFK were tightly clustered between 32 and 70 mg/L, whereas the median concentrations in the SFK and UT watersheds depended strongly on sampling location. Specifically, well MW-12S, which was located in the general deposit area, had the highest median TDS at 446 mg/L. Two other wells had relatively high TDS in the SFK and UT watersheds: wells MW-5M at 178 mg/L (Figure 9.2-6) and SRK2 at 175 mg/L (Figure 9.2-7). These wells were located south of and within the general deposit area, respectively. The balance of the wells in the SFK and UT watersheds had median concentrations that were comparable to the wells in the NFK watershed.

Bedrock: The concentrations of TDS in bedrock ranged from 28 to 59 mg/L in the NFK watershed (Figure 9.2-8), from 23 to 400 mg/L in the SFK watershed (Figure 9.2-9), and from 56 to 233 mg/L in the UT watershed (Figure 9.2-10). Similar to the overburden, the range of median TDS concentrations in the SFK and UT watersheds was quite similar, except for the single well (well MW-12S) that had a much higher concentration. The highest TDS median values were measured in well MW-14D at 234 mg/L (Figure 9.2-9) and SRK3 at 213 mg/L (Figure 9.2-10). Well SRK3 was located in the general deposit area, but well MW-14D is located about 3 miles down-gradient from the general deposit area.

The TDS values were relatively low for a groundwater environment. The low TDS was likely partly due to the types of minerals in the overburden materials. At typical sites, these minerals consist mostly of two types: relatively high-solubility carbonates like calcite and dolomite, and relatively low-solubility silicates like feldspars, micas, and quartz. At this site, the minerals may include a greater proportion of low-solubility silicates rather than more soluble carbonates as reflected in the relatively low TDS concentrations. The low concentrations of dissolved solids were likely also partly due to a relatively high groundwater velocity within the study area. The high velocity decreases the contact time between the groundwater and aquifer minerals, and therefore decreases the mass of minerals that can dissolve.

TDS in groundwater environments is often higher in deep wells than shallow wells, because the TDS in natural groundwater is typically derived from dissolution of the minerals contained in the overburden or bedrock through which the groundwater migrates. This dissolution process is typically time dependent. Therefore, the longer the groundwater is in contact with the overburden or bedrock, the more the minerals dissolve and the higher the TDS. Therefore, the TDS often increases with depth because the flowpaths are longer, which results in longer contact time between the minerals and groundwater. The median TDS of all sampling events increased with depth at eight out of the 11 locations where depth-dependent data were available (Figure 9.2-11). The lower TDS values detected at greater depth at the other three locations might be explained by relatively fast flowpaths leading to those sampling zones.

None of the samples had TDS concentrations that were elevated compared to the most stringent ADEC maximum criteria of 500 mg/L for Alaska waters.

Specific Conductance

Specific conductance is directly correlated with TDS, which was already discussed in this section as was the correlation between specific conductance and TDS.

pH

Overburden: Most of the median field-measured pH values in overburden clustered between 6 and 7 (Figure 9.2-3). Specifically, the median values ranged from 6.0 to 7.5 in the NFK watershed, from 5.3 to

7.6 in the SFK watershed, and from 6.3 to 8.5 in the UT watershed (Figures 9.2-5, 9.2-6, and 9.2-7, respectively). The upper end of each range was due to only one or two wells in each watershed: wells MW-8D in NFK, MW-5M in SFK, and MW-2D and SRK2 in UT (Figure 9.2-3). The lower end of each range was defined by a single well (well MW-1S) in SFK and a cluster of values in the other two watersheds.

Bedrock: The range in median field pH from bedrock was similar to overburden. Specifically, the field pH values ranged from 5.3 to 11.0 in the NFK watershed (Figure 9.2-8), from 4.4 to 8.1 in the SFK watershed, and from 5.9 to 7.6 in the UT watershed (Figures 9.2-9 and 9.2-10). The maximum pH of 11 was measured at well MW-10, where most other values ranged from 6.0 to 6.5. This high value was therefore considered to be a potential outlier. The range in median pH values from bedrock was similar in each watershed, except for the relatively low value of 4.9 at well PQ4 in SFK. This well was located in proximity to the deposit area.

Field pH was outside the range of the most stringent ADEC maximum criterion of greater than 6.5 and less than 8.5 in one or more samples in 33 out of 39 wells. Relatively low pH values (less than 6.3) occurred in low TDS waters such as wells MW-1S (SFK), MW-11SS (SFK), and MW-7S (NFK). The low pH in these waters likely reflected a lack of contact with carbonate minerals that consume hydrogen ions, thereby increasing the pH. Low pH values also occurred in samples having average TDS, for example in wells PQ4, P4S and MW-14D (all located in SFK). These samples had a high sulfate-to-calcium ratio, suggesting that some sulfate may have been provided by the oxidation of pyrite, a process that releases acid and could be responsible for the relatively low pH.

Dissolved Oxygen

The solubility of oxygen in water depends on temperature and atmospheric pressure. After recharge water infiltrates to the groundwater system, the oxygen in groundwater is typically gradually consumed by the oxidation of organic material or minerals such as sulfides. Oxygen concentrations in groundwater remain constant along groundwater flowpaths in the absence of oxidizable materials or decrease in the presence of oxidizable materials. At average field conditions of approximately 4 degrees Celsius (ºC) and 900 feet above sea level (asl), the theoretical solubility of oxygen in water is 12.7 mg/L. This value was calculated using the following formula (ASCE, 1960):

$$DO_{sat} = f \times (14.652 - 0.41022*T + 0.0079910*T^2 - 0.000077774*T^3)$$

Where:

DO_{sat} = dissolved oxygen concentration at saturation

T = temperature in ºC

f = elevation correction = (2116.8 - (0.08 - 0.000115 * T) * E) / 2116.8

E = elevation in feet

Slightly higher concentrations of up to 14.5 mg/L can be reached under colder temperatures, which would be typical of temperatures during spring runoff.

Overburden: The median concentrations of DO in overburden ranged from 12 to 13 mg/L in the NFK watershed, from 0.5 to 13 mg/L in the SFK watershed, and from 0.2 to 13 in the UT watershed (Figures 9.2-5, 9.2-6, and 9.2-7). DO concentrations above 14.5 mg/L (maximum solubility at 0 ºC and 0 feet asl), which were measured in wells MW-8S, MW-7D, and MW-6D, were considered to be potential

outliers but were not flagged as confirmed outliers. The median concentrations of wells with very high DO concentrations remained below the solubility typical of spring melt conditions and were close to the solubility at ambient field conditions.

Bedrock: The median concentrations of DO in bedrock ranged from 11 to 13 mg/L in the NFK watershed, from 0.1 to 13 mg/L in the SFK watershed, and from 0.1 to 5 in the UT watershed (Figures 9.2-8, 9.2-9, and 9.2-10). As such, concentrations were consistently high in the NFK watershed, ranged from low to high in the SFK watershed, and were relatively low in the UT watershed.

Dissolved oxygen was below the most stringent ADEC minimum criterion of 7 mg/L in one or more samples in 22 out of 39 wells. The wells with high DO concentrations of 11 to 14 mg/L reflect the original atmospheric oxygen concentration at the time of recharge, with little interaction with oxidizable materials after infiltration. This includes most wells outside the general deposit area. Within the general deposit area, DO concentrations in several wells were generally low, which may be explained by the reaction of oxygen with sulfide minerals. This interpretation is supported by the high sulfate content of these wells, for example wells MW-12S and P4S. The location of these wells is shown in Figure 9.2-1. Monitoring well MW-14D, which is located in the SFK watershed about 4 miles south of the deposit area, was the only well with low DO concentrations outside the general deposit area.

Concentration versus Depth: Dissolved oxygen concentrations decreased strongly with depth in samples collected from wells P-06-37, MW-14, and MW-5; decreased slightly with depth in wells MW-11, MW-13, P-06-38 and SRK5; and increased or were relatively uniform with depth in wells MW-1, MW-7, MW-8 and MW-12 (Figure 9.2-11). This general trend of DO concentrations most often decreasing with depth was supported by the statistical distribution of DO between overburden and bedrock. On a site-wide basis, DO concentrations were statistically lower in bedrock than overburden, particularly for those concentrations between the 10^{th} and 80^{th} percentile (Figure 9.2-12a).

Correlation with TDS: Dissolved oxygen had a weak inverse correlation with TDS. In other words, the samples with higher TDS generally tended to have lower DO (Figure 9.2-13a).

Temperature

The temperature of groundwater from overburden ranged from 2 to 6 ºC in the NFK watershed, from 1 to 9 ºC in the SFK watershed, and from 1 to 5 ºC in the UT watershed (Appendix 9.2B). The temperature of groundwater from bedrock ranged from 2 to 5 ºC in the NFK watershed, from 2 to 5 ºC in the SFK watershed, and 2 to 4 ºC in the UT watershed. The median temperatures ranged from 2.5 to 5.2 ºC across all the watersheds. As such, groundwater temperatures were very similar between overburden and bedrock, and among the three watersheds. The samples with higher temperatures often originated from shallower wells sampled during spring or summer. The median temperature of all samples was 3 ºC for both the overburden and bedrock wells.

Oxidation-Reduction Potential

Oxidation-reduction potential (ORP) was measured simultaneously with DO in the flow-through cell. The ORP readings tended to vary widely between sampling events even when DO readings were relatively stable. For example, a minimum ORP of -369 millivolts (mV) was recorded at well MW-5D with an associated DO concentration of 0.84 mg/L (Appendix 9.2B). A maximum ORP of 78 mV was recorded with an associated DO concentration of 0.31 mg/L. Although the difference in ORP was 447 mV, the DO

concentrations in these samples were very similar. Other variable values of ORP were recorded for similar DO concentrations at this well, and this type of result was similar at other wells. Overall, the data suggest that the redox state of the groundwater at this site cannot be effectively established using ORP readings. These results are expected for this type of groundwater, which has very low TDS, very low concentrations of constituents with multiple redox states, and near-neutral pH.

Total Suspended Solids

Measurements of total suspended solids (TSS) in groundwater samples are not indicative of the groundwater quality itself because suspended solids do not migrate through the groundwater system. Nevertheless, measurements of TSS are useful for assessing the quality of a groundwater sample because the suspended solids should be as low as possible. One well (P06-38M) had median TSS concentrations of 2,300 mg/L (Appendix 9.2B), which suggests that the filter pack around the screen for this well was likely not adequate. The analyses of total metals from this well may be biased high. Except for this well, the median concentrations of TSS in all the samples of all other wells were 5 mg/L or less. More than half the wells had median TSS concentrations of less than 0.6 mg/L.

Summary of Field and Physical Parameters

In summary, groundwater within the study area was characterized by very low TDS (median concentrations typically less than 100 mg/L), near-neutral pH (most pH values between 6 and 7), an average temperature of 4 ºC, and high DO (most wells greater than 8.5 mg/L). The lowest median pH values were about 5.0. Low DO concentrations (less than 2 mg/L) were observed in only 10 wells (MW-5M and MW-5D, MW-12S and MW-12D, MW-14D, SRK2, SRK3, PQ4, P-06-37D, and P-06-38D), nine of which were located in proximity to the general deposit area. Correlations between the field and physical parameters were not particularly strong, but some general patterns were evident. For example, samples with higher TDS generally tended to be associated with lower DO. Three of the field and physical parameters had ADEC criteria: TDS, pH and DO. None of the samples exceeded the maximum ADEC criterion for TDS. One or more samples were outside the criteria range for pH and DO in 33 and 22 out of 39 wells, respectively.

9.2.5.2. Dissolved Major Ions

The dissolved major ions included the following: calcium, magnesium, sodium, potassium, alkalinity (assumed to be due to dissolved carbonate species), sulfate, chloride, and fluoride. The following paragraphs discuss the major ion composition of the groundwater, as characterized by Piper diagrams, and the concentrations of individual constituents.

Major-Ion Composition of Groundwater

The composition of groundwater chemistry was assessed by presenting the major-ion data on Piper plots (Piper, 1944), which shows the proportion of each constituent in the water in a given sample independent of its absolute concentration. This approach allows the composition of the groundwater sample to be characterized independent of the absolute concentrations. By definition of a Piper plot, the percentage of each constituent on each plot was based on concentrations in milli-equivalents per liter to normalize the effects of ion mass and charge in the interpretation. Piper plots of individual wells are presented in Appendix 9.2E. Groundwater composition based on Piper plots for overburden and bedrock data in individual drainages is discussed in the following paragraphs:

Major Cations: The frequency of detection (FOD) of the major cations (calcium, magnesium, sodium, and potassium) was 100 percent (Table 9.2-2). The major-cation composition in both the bedrock and overburden wells was dominated by calcium but to varying degrees (Figures 9.2-3 and 9.2-4). The lower bound of calcium content was about the same in both cases, but the upper bound was higher for overburden. The range of magnesium content was about the same in overburden and bedrock. Specifically, the cation compositions in overburden were as follows (Figure 9.2-3):

- Calcium ranged from about 35 to 80 percent.
- Sodium and potassium combined ranged from about 10 to 50 percent.
- Magnesium ranged from 10 to 40 percent.

In slight contrast, the proportions of major cations in the bedrock wells were as follows (Figure 9.2-4):

- Calcium ranged from about 30 to 65 percent.
- Sodium and potassium combined ranged from about 5 to 50 percent.
- Magnesium ranged from about 5 to 40 percent.

The following paragraphs discuss major-cation composition by watershed.

- **Overburden.** The cation composition of samples from the overburden wells in the NFK watershed (Figure 9.2-5) was noticeably more uniform than from the overburden wells in the SFK and UT watersheds (Figures 9.2-6 and 9.2-7). Calcium and magnesium are typically released by dissolution of carbonates, while sodium and potassium are typically released by dissolution of silicates. Calcium and magnesium combined in the NFK watershed ranged from about 70 to 85 percent, and sodium and potassium combined ranged from about 15 to 30 percent (Figure 9.2-5). In contrast, most samples from overburden in the SFK and UT watersheds had combined calcium and magnesium that ranged from 50 to 90 percent, and combined sodium and potassium that ranged from 10 to 50 percent (Figures 9.2-6 and 9.2-7). The higher proportion of calcium and magnesium in the SFK and UT watersheds likely reflects the effects of sulfide oxidation in proximity to the deposit. Sulfide oxidation releases acid, which triggers dissolution of calcite and dolomite, and the associated release of calcium and magnesium.

  Bedrock. The cation composition of samples from the bedrock wells in the NFK watershed (Figure 9.2-8) was also noticeably more uniform than from bedrock wells in the SFK and UT (Figures 9.2-9 and 9.2-10). This difference between watersheds is similar to the overburden samples. Calcium and magnesium combined ranged from about 70 to 80 percent; and sodium and potassium combined ranged from about 20 to 30 percent (Figure 9.2-8). In contrast, most samples from bedrock in the SFK and UT watersheds had combined calcium and magnesium that ranged from 60 to 90 percent, and combined sodium and potassium that ranged from 10 to 40 percent (Figures 9.2-9 and 9.2-10). The more uniform composition in the NFK watershed may be due to only two samples having been collected from this watershed. However, the same pattern was evident in both overburden and bedrock. Considering that three times as many samples were collected from overburden as from bedrock, the observed differences likely reflect differences in groundwater chemistry rather than simply being biased by the number of sampling points. The most likely cause of the differences in water quality is the distance of the NFK stations from the

general deposit area, while several stations of the SFK and UT watersheds are located in proximity to the general deposit area.

Major Anions: The major anions include carbonates, sulfate, chloride, and fluoride. The FODs for these anions were as follows: 97 percent for alkalinity, 100 percent for sulfate, 100 percent for chloride, and 69 percent for fluoride (Table 9.2-2). Most samples were dominated by bicarbonate (HCO_3^-), as indicated by the relatively large proportion of carbonate species on the Piper plots (Figures 9.2-3 and 9.2-4). No systematic difference was observed between overburden and bedrock (Figures 9.2-3 and 9.2-4).

- **Overburden.** The anion composition of samples from the overburden in the NFK and UT watersheds (Figures 9.2-5 and 9.2-7) was noticeably more uniform than the composition from the SFK watershed (Figure 9.2-6). In the NFK and UT watersheds, all but one sample had less than 20 percent sulfate and less than 10 percent chloride (Figures 9.2-5 and 9.2-7). By comparison, the samples from overburden in the SFK watershed varied more widely in composition with up to 90 percent sulfate and up to 40 percent chloride. The high-chloride samples were collected from well MW-1S and contained 20 to 40 percent chloride. The rest of the samples from overburden in the SFK watershed contained less than 20 percent chloride (Figure 9.2-6). Sulfate in most samples from overburden varied from 0 to 30 percent. Some samples ranged from 30 to 80 percent sulfate, and two samples were greater than 80 percent sulfate (Figure 9.2-3).
- **Bedrock.** A similar watershed-dependent anion composition was apparent in the bedrock wells. The bedrock wells from the NFK and UT watersheds all contained less than 20 percent sulfate and 10 percent chloride (Figures 9.2-8 and 9.2-10). In contrast, many samples from bedrock wells in the SFK watershed had up to 60 percent sulfate, though with about the same proportion of chloride (Figure 9.2-9). Most samples from bedrock had less than 10 percent chloride and less than 60 percent sulfate. Almost all samples from well PQ4, which had an anion composition of more than 90 percent sulfate, stood out from the other bedrock samples. This well is relatively deep and is completed within the general deposit area.

  The highest chloride contribution occurred in well MW-1S (Figure 9.2-6), which also had one of the lowest median TDS values. This may appear contradictory, since high chloride content in groundwater is normally associated with high salinity. However, rain water often has a high chloride content associated with a low TDS (Appelo and Postma, 1993). The water from well MW-1S, therefore, seems to have very little interaction with the aquifer rock material and probably represents the original precipitation water. This interpretation is consistent with the shallow depth of the screen at well MW-1S (20 to 25 feet), the absence of aquitard material above the screen, and relatively high proportion of sodium and potassium in the water.

Spatial Distribution of Groundwater Composition

While the Piper plots effectively summarized the groundwater composition for all samples, Stiff diagrams were used to simultaneously examine the spatial distribution of groundwater composition and absolute concentrations of the anions and cations. The shape of the polygon indicates the composition while the length of each horizontal axis indicates the parameter concentration. The samples with highest concentrations occurred in the general deposit area (Figure 9.2-14). Concentrations generally decreased with distance from the general deposit area, as indicated by the areas of the Stiff polygons (Figure 9.2-14; Appendix 9.2F). For example, the samples from the nest at well MW-8 in the NFK watershed had lower concentrations than most of the samples from the general deposit area but higher than the other wells in

the NFK watershed. Similarly, well MW-3 in the SFK watershed had lower concentrations than the wells in the general deposit area but higher than other wells in the SFK watershed that were further from the general deposit area. Well MW-14D in the SFK watershed was an exception to this trend; this well had concentrations of calcium, magnesium, and sulfate that were comparable to wells in the general deposit area.

Except for well MW-14D, a similar trend was evident with respect to the composition of the groundwater. The wells that were furthest from the general deposit area (i.e., wells MW-1, MW-2, MW-6, MW-7, MW-9D, MW-10, MW-11, and MW-13) consistently had the lowest proportion of sulfate compared to other wells on site, as indicated by the shapes of the Stiff polygons (Figure 9.2-14; Appendix 9.2F). All of these wells had calcium as the dominant cation and bicarbonate as the dominant anion. The wells that were closest to the general deposit area (wells MW-5 and MW-12; PQ4, SRK2, and SRK5; KP-P4 and P4-S) often had higher proportions of sulfate and magnesium, and sometimes higher proportions of sodium and potassium relative to the wells that were furthest from the general deposit area. The wells at intermediate distances from the deposit area (wells MW-3 and MW-8) also sometimes had slightly elevated proportions of sulfate and magnesium. The higher proportions of sulfate were likely due to oxidation of sulfide minerals from the mineralized zone in the general deposit area. The higher proportions of calcium, magnesium, and sodium were likely due to acid neutralization reactions with carbonate and silicate minerals, respectively. Wells MW-14D had the highest concentration of sodium among all samples and also was the only location where the samples had simultaneously high sodium and sulfate concentrations.

The three wells in overburden that had relatively high major-ion concentrations and pH, and relatively low DO (wells MW-5M, MW-12S, and SRK2; Figures 9.2-3 and 9.2-14) were all relatively close to the general deposit area. The two wells in bedrock that had relatively high TDS and pH, and relatively low DO (wells MW-5D and SRK3; Figures 9.2-4 and 9.2-14) were also located relatively close to the general deposit area. These results support the interpretation that the deposit has influenced the groundwater quality in the study area.

The following paragraphs discuss the major-ion concentrations individually. Time series plots of each of the major ions are presented in Appendix 9.2G.

Calcium

Thirty-three out of 39 wells had calcium concentrations less than 25 mg/L, and 24 out of 39 wells had concentrations less than 10 mg/L (Figure 9.2-15). Three wells in the study area had noticeably higher calcium concentrations than all of the other wells: MW-12S (overburden in SFK), SRK3 (bedrock in UT), and MW-14D (SFK). Wells MW-12S and SRK3 were located close to the general deposit area, while well MW-14D was located south of Frying Pan Lake. These wells had median calcium concentrations of 82, 51, and 46 mg/L, respectively, and also had relatively low DO (Table 9.2-3). The wells in the NFK watershed had median concentrations that were always less than 12 mg/L, whereas many wells in the SFK and UT watersheds had median concentrations that were greater than 12 mg/L (Figure 9.2-15). The wells in the UT watershed had concentrations less than 20 mg/L except for SRK2 and SRK3, which were located close to the general deposit area.

Magnesium

Thirty-one out of 39 wells had magnesium concentrations less than 5 mg/L, and 22 out of 39 wells had concentrations less than 2 mg/L (Figure 9.2-15). The following wells had median magnesium concentrations greater than 5 mg/L:

- P06-37D 7 mg/L
- MW-5D 9 mg/L
- MW-5M 11 mg/L
- SRK2 12 mg/L
- SRK3 22 mg/L
- MW-12S 30 mg/L

All of these wells were located relatively close to and down-gradient of the general deposit area. Of these wells, MW-5M, MW-12S, and SRK2 had relatively high pH and TDS, and low DO (Table 9.2-3).

Hardness

The hardness of a sample is the sum of total calcium and total magnesium (i.e., unfiltered) concentrations expressed as equivalent mg/L of calcium carbonate ($CaCO_3$). For example, a sample with a calcium concentration of 18.5 mg/L and a magnesium concentration of 4.0 mg/L has a hardness of 62.7 mg/L expressed as $CaCO_3$. Because hardness is expressed in terms of equivalent $CaCO_3$, the reported concentrations are larger than the sum of the calcium and magnesium.

All but six of the wells had hardness less than 77 mg/L (Appendix 9.2B). With one exception (P06-38M), the wells with hardness greater than 77 mg/L were the same samples that had the highest calcium, magnesium, or combined calcium and magnesium, as follows:

- MW-5D 98 mg/L
- MW-14D 114 mg/L
- SRK2 115 mg/L
- MW-5M 128 mg/L
- P06-38M 146 mg/L
- SRK3 213 mg/L
- MW-12S 327 mg/L

The relatively high hardness in samples from P06-38M was probably due to the high suspended solids in those samples. Because the hardness is based on total concentrations (i.e., unfiltered) and this well had unusually high suspended solids, the hardness was higher than indicated by the dissolved concentrations of calcium and magnesium.

Sodium

Thirty-two out of 39 wells had median sodium concentrations less than 7 mg/L (Figure 9.2-15). The following wells had relatively elevated sodium median concentrations compared with other sampling locations at the site:

- MW-5M 10 mg/L
- MW-5D 12 mg/L
- MW-12S 14 mg/L
- P06-38D 21 mg/L
- SRK2 27 mg/L
- MW-14D 36 mg/L
- P06-37D 32 mg/L

Except for well MW-14D, these wells are in proximity to the general deposit area. The origin of the sodium is likely the dissolution of silicate minerals such as feldspar. Of these wells, MW-5M, MW-12S, and SRK2 had relatively high pH, TDS, and calcium concentrations, and low DO concentrations (Table 9.2-3). Well MW-5D also had relatively low DO and relatively high magnesium. Well MW-14D had a composition that was different than any other well in the study area, characterized by simultaneously large proportions of sulfate and sodium (Figure 9.2-14).

Potassium

Twenty-six out of 39 median potassium concentrations were less than 0.6 mg/L, and the highest median concentration (well MW-12S) was 2.7 mg/L (Figure 9.2-15). None of the wells had particularly elevated potassium relative to other wells. However, except for well MW-14D, all wells with concentrations greater than 0.6 mg/L were located in proximity to the general deposit area. Other than well MW-12S, only MW-5D had a median potassium concentration greater than 2 mg/L.

Alkalinity

Thirty-four out of 39 median alkalinity concentrations were less than 75 mg/L as $CaCO_3$ (Figure 9.2-16). The following wells had median alkalinity values above 75 mg/L:

- P-06-37D 125 mg/L
- MW-5M 129 mg/L
- SRK2 156 mg/L
- MW-12S 178 mg/L
- SRK3 226 mg/L

All of these wells were located in proximity to the general deposit area. Wells MW-5M, MW-12S, and SRK2 also had relatively high TDS, pH, magnesium and sodium, and relatively low DO (Table 9.2-3).

Unlike most other parameters, the most stringent ADEC criterion for alkalinity is a minimum value; the alkalinity should be above the criterion concentration of 20 mg/L $CaCO_3$. The smallest ratio relative to

the criterion was 0.2 (Appendix 9.2D). The alkalinity in many water samples was relatively low for groundwater; and, consequently, the median concentrations did not satisfy the minimum surface-water criterion for alkalinity in 13 of 39 wells (Appendix 9.2D). In wells MW-11M, MW-11S, MW-11SS, MW-13S, MW-1S, and SRK5D, none of the measurements met the minimum criterion. All of these wells are located in the SFK watershed and, except for SRK5D, are more than 4 miles from the general deposit area.

Sulfate

Median sulfate concentrations were divided into three groups: less than 20 mg/L (30 wells); 20 to 60 mg/L (seven wells); and 90 to 175 mg/L (2 wells; Figure 9.2-16). The wells in the second group comprised the following: MW-3D, MW-5M, MW-5D, MW-12D, P4S, and PQ4. Wells in the third group comprised MW-12S and MW14-D. Wells MW-12S and MW-14D also had relatively high TDS, pH, calcium, magnesium and sodium, and relatively low DO (Table 9.2-3). Except for PQ4, the wells with the highest sulfate concentrations also generally had relatively elevated calcium, magnesium, and alkalinity. The wells with relatively high sulfate concentrations were in proximity to the general deposit area. None of the wells had any samples with concentrations higher than the most stringent maximum ADEC water criterion of 250 mg/L (Figure 9.2-16); the largest ratio relative to the criterion was 0.86, which occurred in well MW-12S (Appendix 9.2D).

Chloride

All but two wells had median chloride concentrations of about 0.8 mg/L (Figure 9.2-16). Even in well nests where the chemistry for all other parameters was different, the chloride concentrations were generally very similar. These concentrations likely reflect the original chloride concentration in the infiltrated rain water and a lack of a chloride source in the subsurface. Wells MW-14D and P-06-37D had noticeably higher median concentrations of about 9 and 4 mg/L, respectively. The occurrence of higher chloride concentrations and a unique combination of other characteristics at well MW-14D, including high sulfate, sodium, and a trend toward higher concentrations over time, suggests the presence of one or more geochemical processes that were not occurring at other locations. All samples were considerably below the most stringent ADEC water quality criterion for chloride of 230 mg/L (Appendix 9.2D).

Fluoride

Fluoride comprises an extremely small proportion of the major ions. The median concentrations of fluoride were all less than 0.25 mg/L, and all but four wells had concentrations less than 0.08 mg/L (Figure 9.2-16). Similar to other constituents, the wells in the NFK watershed had the lowest concentrations (all less than 0.05 mg/L). The following wells had the highest fluoride concentrations (greater than 0.08 mg/L):

- P4S 0.13 mg/L
- P06-37D 0.16 mg/L
- MW-5M 0.18 mg/L
- MW12S 0.21 mg/L
- MW-5D 0.27 mg/L

All samples were considerably below the most stringent ADEC criterion for fluoride of 1 mg/L.

Summary of Major Ions

In summary, the major-ion concentrations were generally uniform with some selected anomalies where the concentrations were noticeably higher, namely the MW-5, MW-12, MW-14, and SRK5 well nests in the SFK watershed. The MW-5 nest also had anomalously low DO concentrations, whereas the SRK5 nest had DO concentrations near the solubility limit (Table 9.2-3). The major-ion composition of the groundwater samples across the site can be described as calcium-magnesium-bicarbonate, except for wells P-06-37 and P-06-38 in the UT watershed, which were of type sodium-bicarbonate, wells PQ4 and SRK5D near the general deposit area, which were of type calcium-sulfate, and well MW-14D, which was of type calcium-sodium-sulfate. This description indicates that the cations were generally dominated by calcium rather than magnesium, sodium, or potassium; and the anions were generally dominated by bicarbonate rather than sulfate or chloride. Except for alkalinity, all of the major ions had concentrations that satisfied the lowest criterion specified in the QAPP (Appendix G of the EBD).

9.2.5.3. Nutrients

The nutrients measured in the groundwater included total ammonia, nitrate plus nitrite, phosphorous, and total orthophosphate. The following paragraphs discuss each of the constituents in turn.

Total Ammonia

Total ammonia as N was detected in 22 percent of the samples (Table 9.2-2; Appendix 9.2B). All median concentrations were well below the most stringent ADEC maximum criterion of 0.18 mg/L (Figure 9.2-17; Appendix 9.2D). One well (MW-14D) had regularly detectable total ammonia, with a median concentration of 0.13 mg/L (Figure 9.2-17). As discussed, this well also stood out as a well with major ion composition that was relatively unique within the study area.

Nitrate and Nitrite

Combined nitrate and nitrite was detected in 76 percent of the samples (Table 9.2-2; Appendix 9.2B). The dominance of nitrate and nitrite over ammonia is consistent with the generally high DO concentrations in the groundwater, which would tend to maintain nitrogen in an oxidized form. Median concentrations ranged from about 0.05 to 0.5 mg/L (Figure 9.2-17). No wells had particularly high or low concentrations, and no values exceeded the most stringent ADEC maximum criterion of 10 mg/L (Figure 9.2-17; Appendix 9.2D). The largest ratio relative to the criterion for nitrate was 0.12, and the largest ratio for nitrite was 0.10 (Appendix 9.2D).

Orthophosphate

Orthophosphate was detected in 5 percent of the samples (Table 9.2-2; Appendix 9.2B). Most median concentrations were below 0.1, only two wells had higher median values, namely PQ4 (0.17 mg/L) and MW12D (0.35 mg/L) (Figure 9.2-17).

Total Phosphorous

Total phosphorous was detected in 92 percent of the samples (Table 9.2-2; Appendix 9.2B). Median concentrations ranged from 0.006 to 1.3 mg/L and were generally highest in the SFK and UT watersheds (Figure 9.2-17). The four wells that stood out with the highest concentrations of all were in the SFK watershed:

- MW12D 0.30 mg/L

- MW-5D 0.56 mg/L
- P-06-38D 0.42 mg/L
- P-06-38M 1.29 mg/L

Summary of Nutrients

In summary, nitrate-nitrite and phosphorous occurred regularly but at low concentrations throughout the study area, while ammonia was regularly detected only in well MW-14D. No spatial trends were apparent, and median concentrations were all below the respective maximum criteria.

9.2.5.4. Trace Elements

The trace elements include all other constituents besides the field and physical parameters, the major ions and the nutrients, as follows: aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc. These constituents typically occur at relatively low or trace concentrations in natural groundwater but form an important part of the baseline geochemical characterization.

The following paragraphs focus on the results for dissolved concentrations (filtered samples). These concentrations most closely represent the actual groundwater quality because suspended solids do not migrate through groundwater systems. The results for total concentrations (unfiltered samples) reflect the quantity of TSS in the well and do not reflect the actual groundwater quality. The concentrations of dissolved trace elements are presented on box and whisker plots (Figures 9.2-18 to 9.2-22) and as statistical distributions (Figures 9.2-12a and 9.2-12b). The trace-element dissolved and total concentrations were compared with the respective water-quality criterion (Appendix 9.2D) to provide a context for the data in the same manner as the major ions. Hardness dependent criteria are preliminary estimates based on existing baseline hardness data.

Aluminum

Dissolved aluminum was detected in 57 percent of the samples (Table 9.2-2). Median dissolved aluminum concentrations were between 1.0 and 10.0 micrograms per liter (µg/L) at all but two locations (Figure 9.2-18). The most stringent maximum criterion of 87µg/L was exceeded by all of the dissolved analyses in well PQ4, which was located in proximity to the general deposit area. Wells P-06-38M and SRK5M also had samples that exceeded the criterion. The median concentration in this well was an order of magnitude greater than all other wells.

Total aluminum exceeded the most stringent ADEC maximum criterion of 87 µg/L in 14 out of 39 wells. Particularly high median values were reached in wells P-06-38M (1,630 µg/L), PQ4 (210 µg/L), SRK2 (3.3 µg/L), MW-1S (8.5 µg/L), and SRK5S (5.9 µg/L). The unusually high values in well P-06-38M were due to the unusually high TSS in that well and do not represent the actual groundwater quality.

Antimony

Dissolved antimony was detected in 66 percent of the samples. All but one of the samples across all wells had antimony concentrations between 0.01 and 0.3 µg/L (Figure 9.2-18). Median dissolved concentrations were all below 0.25 µg/L, and all dissolved and total samples had concentrations less than the most stringent maximum criterion of 5.6 µg/L. Wells MW-5D, MW-12D, MW-14D, PQ4, P-06-37M,

P-06-37D, and P-06-38D had relatively high median concentrations. These wells are located in proximity to the general deposit area. Antimony concentrations were statistically slightly higher in bedrock wells than in the overburden above approximately the 60th percentile (Figure 9.2-12a).

Arsenic

Dissolved arsenic was detected in 50 percent of the samples. Median dissolved arsenic concentrations ranged from about 0.1 to 49.0 µg/L, but most wells had median concentrations between 0.1 and 10 µg/L (Figure 9.2-18). Wells that had median concentrations greater than 2 µg/L included the following: MW-14D, MW-5D, MW-5M, MW-2D, PQ4, P-06-37D, P-06-38M, and P-06-38D. All of these wells were located in proximity to the general deposit area. Elevated arsenic concentrations were typically associated with low DO (Table 9.2-3). The single sample from well P-06-38D was the one that had an arsenic concentration of 49 µg/L, which was above the most stringent ADEC maximum criterion of 10 µg/L (Appendix 9.2D). This sample is the only one that exceeded the criterion and might be an outlier. However, it was not marked as an outlier because only one sample was collected for this well. Arsenic is often associated with sulfide minerals, and the dissolution of such minerals is a likely source of the dissolved arsenic in these wells.

Total arsenic concentrations were similar to the dissolved concentrations, with values above 2 µg/L for the same wells and an extreme value of 49 µg/L at well P-06-38D. Exceeding values were found for wells MW-2D, P-06-38D, P06-38M, and PQ4. None of the median values exceeded the most stringent ADEC criterion of 10 µg/L, except for the single measurement for P06-38D.

Barium

Dissolved barium was detected in 100 percent of the samples. Median dissolved concentrations of barium ranged from about 0.5 to 480 µg/L, but most wells had median concentrations less than 20.0 µg/L (Figure 9.2-18). Wells MW-5M, MW-12S, SRK2, SRK3, P-06-37D, P-06-38M, and P-06-38D had relatively high concentrations compared to other wells at the site. These wells are located in proximity to the general deposit area. These wells include several that had low DO (Table 9.2-3). All median values were well below the most stringent ADEC maximum criterion of 1,000 µg/L.

Median total concentrations for barium were higher than dissolved concentrations for a few wells and reached up to 540 µg/L in P06-38M and 378 µg/L in SRK3. All total concentrations remained below the most stringent ADEC maximum criterion of 1,000 µg/L.

Beryllium

Dissolved beryllium was detected in only 5 percent of the samples (95 percentile method detection limit [MDL] of 0.025 µg/L). All of the samples with detectable concentrations were more than an order of magnitude lower than the most stringent ADEC maximum criterion of 4.0 µg/L (Figure 9.2-19). Bedrock wells had a higher percentage of detects than the overburden wells, and most detected values were also higher than samples from the overburden.

Total beryllium was also detected rarely, and the maximum median was reached in well P-06-38M with a value of 2 µg/L. None of the total beryllium concentrations exceeded the most stringent ADEC maximum criterion.

Cadmium

Dissolved cadmium was detected in only 11 percent of the samples (95 percentile MDL of 0.015 µg/L). All wells but one (PQ4) had median dissolved concentrations much less than the most stringent ADEC maximum criterion of 0.1 µg/L (Figure 9.2-19). Well PQ4 had a median concentration of 0.25 µg/L, which was above the criterion and about an order of magnitude higher than the other wells (Figure 9.2-19). Well PQ4 was the only well that had relatively high median concentrations of many other metals, including aluminum, arsenic, antimony, copper, iron, molybdenum, selenium and zinc, and relatively low pH values (Table 9.2-3). Additionally, this well is located in proximity to the general deposit area.

Median total concentrations of cadmium were similar to the dissolved concentrations. Well P-06-38M had a median total concentration of 0.4 µg/L, and PQ4 had a median total concentration of 0.25 µg/L. Four additional wells had occasional total cadmium exceedences of the most stringent ADEC maximum criterion of 0.1 µg/L, namely wells MW-10, MW-13D, MW-2D, and SRK5M.

Chromium

Dissolved chromium was detected in 82 percent of the samples. Most median dissolved chromium concentrations were between 0.1 and 1.0 µg/L (Figure 9.2-19). Slightly higher median concentrations above 1 µg/L were found in wells MW-2D, MW-5S, P-06-38M, and SRK2. None of the wells had concentrations that were much higher than other wells. All samples were less than the most stringent ADEC maximum criterion of 24 µg/L.

Total chromium concentrations were noticeably more elevated, and 18 of 39 wells were above 1 µg/L; the highest median value of 48 µg/L was found in P06-38M. P06-38M was the only well where total chromium exceeded the most stringent ADEC maximum criterion of 24 µg/L .

Copper

Dissolved copper was detected in 96 percent of the samples. Most median dissolved copper concentrations were between 0.1 and 1.0 µg/L (Figure 9.2-19). Five wells had median concentrations that were higher than the most stringent maximum criterion of 2.7 µg/L.

- MW-12S 3 µg/L, 56 percent of samples exceeded the most stringent ADEC maximum criterion
- SRK5D 4 µg/L, 75 percent of samples exceeded the most stringent ADEC maximum criterion
- MW-1M 6 µg/L, 67 percent of samples exceeded the most stringent ADEC maximum criterion
- P-06-38M 76 µg/L, 100 percent of samples exceeded the most stringent ADEC maximum criterion
- PQ4 1,045 µg/L, 100 percent of samples exceeded the most stringent ADEC maximum criterion

These five wells had concentrations that were noticeably higher than in the other wells. The copper concentration in PQ4 was particularly elevated relative to the other wells. Wells SRK5D, P06-38M, and

PQ4 were located in proximity to the general deposit area and the copper in these samples was probably released from the deposit. Well MW-1M was located about 9 miles along the SFK from the deposit area.

Total copper concentrations exceeded the most stringent ADEC maximum criterion of 2.7 µg/L in 6 of 39 wells. PQ4 was again particularly elevated relative to all other wells (1.2 mg/L), and MW-1M, P06-38M, and SRK5D also had elevated total concentrations.

Iron

Dissolved iron was detected in 58 percent of the samples. Median dissolved iron concentrations ranged from about 3 to 1,700 µg/L (Figure 9.2-20). Median iron concentrations from the following wells were above the most stringent ADEC maximum criterion of 1,000 µg/L:

- P-06-38M 1,700 µg/L
- MW-5D 1,200 µg/L

Most of the median iron concentrations were below 30 µg/L. High iron concentrations were expected to occur in wells with low DO, since iron oxide and hydroxide minerals are more soluble under reducing conditions. This was confirmed for the seven highest iron median concentrations encountered in wells PQ4 and MW-5D. Iron concentrations in these wells were greater than 1,100 µg/L, and DO was below 0.1 mg/L (Table 9.2-3). All wells with relatively high iron concentrations were located in proximity to the general deposit area.

Ten wells had median total concentrations of greater than 30 µg/L. The most stringent ADEC maximum criterion of 300 µg/L for total iron concentration was exceeded in two wells.

Lead

Dissolved lead was detected in only 20 percent of the samples. Median dissolved concentrations of lead ranged from 0.02 to 0.8 µg/L (Figure 9.2-20). With a median concentration of 0.19 µg/L, the bedrock wells seemed to have slightly higher lead concentrations than in the overburden, where the median was 0.13 µg/L. Well P-06-38M had noticeably higher concentrations relative to other wells, and the median concentration was above the most stringent ADEC maximum criterion of 0.54 µg/L. Well P-06-38M was the only one with concentrations above the most stringent ADEC criterion.

Total lead concentrations were slightly higher than dissolved concentrations, and well P-06-38M was the only well with values above the most stringent ADEC maximum criterion of 0.54 µg/L.

Manganese

Dissolved manganese was detected in 95 percent of the samples. Most median dissolved concentrations of manganese ranged from about 0.1 to 10 µg/L (Figure 9.2-20). However, 10 wells had higher median concentrations that were also above the most stringent ADEC maximum criterion of 50 µg/L:

- SRK2 70 µg/L
- P-06-37D 70 µg/L
- P-06-38D 100 µg/L
- SRK3 140 µg/L

- MW-14D 230 µg/L
- MW-12S 260 µg/L
- MW-5M 280 µg/L
- P-06-38M 283 µg/L
- MW-5S 472 µg/L
- MW-5D 900 µg/L

The high manganese concentrations in the MW-5 well nest were consistent with the relatively low DO concentrations, which tend to allow manganese oxides to become unstable and dissolve over time. In general, wells that had relatively high manganese concentrations also had relatively high iron concentrations (Table 9.2-3). This correlation was expected because manganese oxide dissolution often follows iron oxide dissolution. Except for well MW-14D, all wells with relatively high manganese concentrations were located in proximity to the general deposit area.

Total concentrations were similar to the dissolved concentrations except for well P-06-38M, which had a median concentration of 2,500 µg/L. This high concentration is due to the high TSS in this well and does not represent actual groundwater quality. The most stringent ADEC maximum criterion of 50 µg/L was exceeded at least once in 9 out of 39 wells.

Mercury

Dissolved mercury was detected in only 11 percent of the samples (95 percentile MDL of 0.06 µg/L). Up to March 2006, the mercury detection limit was 0.062 µg/L, which was above the most stringent ADEC maximum criterion of 0.05 µg/L. The detection limit was subsequently lowered to 0.0009 µg/L, starting with the March 2006 sampling round. Exceedences were found at wells MW-7D, SRK5D, and SRK5S, but all median concentrations in all wells were below the most stringent ADEC maximum criterion.

Total mercury concentrations exceeded the most stringent ADEC maximum criterion of 0.05 µg/L only at well MW-7D.

Molybdenum

Dissolved molybdenum was detected in 94 percent of the samples. Median dissolved concentrations ranged from 0.05 to 13 µg/L (Figure 9.2-21). Well MW-12D, which is located close to the general deposit area, had a median concentration of 13 µg/L, which is above the most stringent ADEC maximum criterion of 10 µg/L. Median concentrations in wells MW-12S (9.5 µg/L) and PQ4 (9.3 µg/L) were just below the criterion. The following wells had relatively high median concentrations of molybdenum compared with other wells: MW-3D; MW-5S, MW-5M, and MW-5D; MW-12S and MW-12D; MW-13D; MW-14D; PQ4; SRK2; SRK5M and SRK5D; and P06-37D (Figure 9.2-21). Except for SRK2, which is close to the SFK/UT watershed boundary, all of these wells were located in the SFK watershed but were not necessarily located in proximity to the ore deposit. Bedrock wells had a noticeably higher median concentration of 1.3 µg/L as compared to the overburden wells, which had a median concentration of 0.25 µg/L (Figure 9.2-12a). Concentrations above the median for a given well were always higher in bedrock than in overburden (Figure 9.2-12a). Dissolved molybdenum concentrations exceeded the maximum ADEC criterion of 10 µg/L only in well MW-12D.

Total concentrations of molybdenum were very similar to the dissolved concentrations and ranged as high as 13 µg/L in well MW-12D. Concentrations of total molybdenum exceeded the maximum ADEC criterion of 10 µg/L only in wells MW-12D and PQ4.

Nickel

Dissolved nickel was detected in 98 percent of the samples. Median dissolved nickel concentrations ranged from 0.13 to 4.0 µg/L (Figure 9.2-21). All of the samples had concentrations that were less than the most stringent ADEC maximum criterion of 16 µg/L, and none of the wells had noticeably higher concentrations than other wells. The statistical distribution of nickel concentrations in bedrock and overburden wells was very similar up to approximately the 80th percentile. Above this percentile, overburden concentrations tended to be higher (Figure 9.2-12b).

None of the total concentrations was above the most stringent ADEC maximum criterion of 16 µg/L.

Selenium

Dissolved selenium was detected in only 17 percent of the samples (95 percentile MDL of 0.31 µg/L). All samples had dissolved selenium concentrations less than the most stringent ADEC maximum criterion of 4.6 µg/L (Figure 9.2-21). Wells MW-3D, MW-12S, MW-12D, PQ4, and SRK5D had the highest median concentrations. Most of these wells were located in proximity to the general deposit area.

Total selenium concentrations were very similar to the dissolved concentrations and the maximum median concentration was found in well MW-12D at a value of 1.5 µg/L. All total concentrations were below the most stringent ADEC maximum criterion of 4.6 µg/L.

Silver

Dissolved silver was detected in only 2 percent of the samples (95 percentile MDL of 0.0062µg/L). All samples had dissolved silver concentrations less than the most stringent ADEC maximum criterion of 0.32 µg/L (Figure 9.2-21). None of the wells had noticeably higher median concentrations than other wells.

Total silver FOD and concentrations were slightly higher than the dissolved values, and the median of well P-06-38M reached 0.3 µg/L. Wells MW-2D, P-06-38M, and PQ4 had one or more values above the most stringent ADEC maximum criterion of 0.32 µg/L , but none of the medians exceeded the criterion.

Thallium

Dissolved thallium was detected in only 6 percent of the samples (95 percentile MDL of 0.0125 µg/L). All dissolved thallium concentrations were less than the most stringent ADEC maximum criterion of 0.24 µg/L (Figure 9.2-22). Wells SRK5D, PQ4, and P-06-38M had higher median concentrations than the other wells and also had a higher frequency of detection.

None of the other wells had total concentrations exceeding the most stringent ADEC maximum criterion of 0.24 µg/L.

Vanadium

Dissolved vanadium was detected in 43 percent of the samples. All samples had dissolved concentrations less than the most stringent ADEC criterion of 100 µg/L (Figure 9.2-22). None of the wells had noticeably higher concentrations than other wells, and none of the concentrations exceeded the most stringent ADEC maximum criterion.

As with dissolved concentrations, none of the concentrations of total vanadium exceeded the most stringent ADEC maximum criterion of 100 µg/L.

Zinc

Dissolved zinc was detected in 58 percent of the samples. All wells, except for PQ4, had median dissolved concentrations less than the most stringent ADEC maximum criterion of 36 µg/L . The samples from PQ4 had a median concentration of 38 µg/L compared with the criterion of 36 µg/L. This well is located in proximity to the general deposit area. Well MW-1M had a median concentration of 13 µg/L, and two samples had concentrations above the most stringent maximum criterion. All other wells had median zinc concentrations below 5 µg/L. The FOD and the statistical distribution of concentrations were very similar in bedrock and overburden wells.

Three wells had one or more total concentrations above the most stringent ADEC maximum criterion of 36 µg/L. The highest of these concentrations were found in well P-06-38M (176 µg/L) and PQ4 (38 µg/L). The high total concentrations measured in well P-06-38M were due to the high TSS and likely do not represent actual groundwater quality. This concentration was not marked as an outlier because the data set contained only four points.

Comparison of Concentrations from Bedrock and Overburden

For most parameters, the statistical distribution of concentrations was very similar in bedrock and overburden through the first 50 to 75 percentile of the data (Figures 9.2-12a and 9.2-12b). Above the 75 percentile concentration, the concentrations in bedrock were often higher, indicating that the highest concentrations tended to occur in bedrock. For oxygen, this pattern was opposite, and the 50 percentile concentrations in the bedrock wells were considerably lower than in the overburden wells (Figure 9.2-12a). This result indicated that the lowest concentrations, although relatively infrequent, tended to occur in bedrock wells. On the other hand, concentrations of oxygen above 75 percentile were very similar in bedrock and overburden, which indicated that high concentrations could occur in both overburden and bedrock. For sulfate, the concentrations were similar in bedrock and overburden below 60 percentile, higher in bedrock than overburden between 60 to 95 percentiles, and lower in bedrock than overburden above 95 percentile. The shape of the cumulative frequency curve for bedrock wells was more irregular than for the overburden wells, suggesting that several populations were superimposed rather than consisting of one homogenous population.

Summary of Trace Elements

In summary, the concentrations of trace elements in groundwater were generally below the most stringent ADEC maximum water quality criterion. In proximity to the general deposit area, generally one or two wells had median concentrations that were higher than the most stringent maximum criterion for aluminum (PQ4), arsenic (well P-06-38D, only one sample), copper (wells PQ4, MW-1M, SRK5D), cadmium (PQ4), iron (well MW-5D), lead (well P-06-38M), manganese (10 wells), molybdenum (well

MW-12D), and zinc (PQ4). Some of the wells with relatively elevated concentrations of trace metals were the same wells that had relatively high TDS, relatively low pH, and relatively low DO. The highest concentrations of dissolved ions tended to occur in bedrock wells, and the few wells that had low DO tended to be completed in bedrock.

9.2.5.5. Cyanides

Total cyanide was detected in only 4 percent of the samples, and weak-acid-dissociable cyanide was detected in only 6 percent of the samples. The 95-percentile detection limits for total and weak acid dissociable (WAD) cyanide were 0.002 mg/L. Concentrations of weak-acid-dissociable cyanide exceeded the most stringent maximum ADEC criterion of 5.2 µg/L in only one sample each at wells MW-8D and MW-10.

9.2.5.6. Constituent Correlations

Parameter correlation can be a useful tool to understand the origin of some dissolved constituents in groundwater because minerals release ions in stoichiometric proportions as they dissolve. With the progressive reaction of a mineral along a groundwater flowpath, the dissolved elements accumulate in the solution; but the ratio between the ions remains constant, assuming other reactions do not influence the concentrations of these constituents. Under these conditions, two constituents will correlate on a line with a positive slope when plotted on a scatter plot if the process releases both constituents and on a line with a negative slope if the process releases one constituent and consumes another. The dissolution of dolomite ($CaMg(CO_3)_2$) is a good example of positive correlation. This reaction will increase dissolved calcium, magnesium, and alkalinity along the flowpath, and the ratio between these two parameters expressed in milli-equivalents per liter (meq/L) will remain 1:1:2, reflecting the mineral formula, other factors being equal. The oxidation of sulfide minerals is a good example of a negative correlation in the study area since this reaction consumes oxygen and produces dissolved sulfate. While some parameter correlations are often evident in groundwater systems, typical natural systems include a large number of competing rock-water reactions rather than a few dominant non-competing reactions. Therefore, typically only a few rock-water interactions can be discerned from parameter correlations.

Calcium was positively correlated in overburden and bedrock wells with TDS, magnesium, and bicarbonate (i.e., alkalinity; Figure 9.2-13a and 13b), suggesting that carbonate dissolution controlled the concentrations of these elements in most samples and that carbonates were responsible for a large proportion of TDS in groundwater samples. Calcium and bicarbonate would be released by dissolution of calcite or dolomite; magnesium would be released by dissolution of magnesium calcite or dolomite. Calcium was generally poorly correlated with sulfate (Figure 9.2-13a), suggesting that gypsum was not the primary contributor of calcium or sulfate to groundwater if at all.

Dissolved oxygen concentrations in overburden wells were generally negatively correlated with TDS and sulfate (Figure 9.2-13a). This inverse relationship suggests that sulfides were being oxidized by oxygen in some areas of the site, probably in proximity to the general deposit area. In this scenario, oxygen would be consumed by sulfide oxidation, which would account for the negative correlation. Sulfate would be released from the sulfides themselves, and calcium would be released from carbonates that would dissolve to neutralize the acid produced during sulfide oxidation. The equivalents of molybdenum, manganese, and iron were also somewhat inversely correlated with oxygen, suggesting these metals were also released during sulfide oxidation (Figure 9.2-13b).

Some parameter pairs did not correlate as well as expected, for example, sodium and silica (feldspar dissolution; Figure 9.2-13b). This lack of correlation may be explained by additional sources of sodium, such as ion exchange, or sinks for silica, such as precipitation of amorphous silica.

In summary, many constituents were not correlated, but some key correlations were identified that suggest the following:

- Sulfide minerals have been oxidizing.
- Carbonates account for most of the dissolved solids.
- The carbonates likely contain magnesium.
- Some metals were likely released as a result of sulfide oxidation.

9.2.5.7. Temporal Trend Analysis

Temporal trends in geochemical monitoring data indicate changes to the geochemical equilibrium of the system. Temporal trends, other than seasonal cycles, are rare in natural groundwater systems because these systems are usually old enough that equilibrium has been reached. Sometimes short-term trends are identified after a well is installed that reflect the response to a short-term disequilibrium caused by the well installation. If such trends are identified, these data should be flagged accordingly and excluded from interpretation of ambient groundwater conditions.

Most trends identified by the Mann Kendall test were rejected upon visual inspection either because the concentration changes were deemed insignificant or because the trend was no longer present by 2008. The visual inspection of the time series plots showed that most trends were strongest in the first three to four sampling events and then equilibrated to the natural groundwater conditions. Classic examples of this behavior included barium at well MW-12D and cobalt at well MW-12S (Appendix 9.2I). In well MW-5S, arsenic varied up and down seasonally but decreased year to year up to 2008, then leveled at a concentration of about 0.6 µg/L in 2008. Decreasing concentrations were far more common than increasing concentrations during the early sampling events. Most parameters had decreasing trends early in the sample record; typically only iron and copper had increasing trends early in the sample record.

The following ongoing trends were identified (Appendix 9.2I):

- MW-13D – decreasing for barium.
- MW-14D – increasing for boron, arsenic, alkalinity, sodium, sulfate, and TDS.
- MW-9D – increasing for calcium and sodium.
- SRK3 – increasing for alkalinity.

Slow equilibration seemed to be more common for increasing than for decreasing trends. Well MW-14D stood out as the well with the strongest increasing trends, including TDS, which increased from 150 mg/L in 2005 to 400 mg/L in 2008. These trends are more difficult to explain by the normal equilibration process that occurs after installing a monitoring well. Increasing trends of metals could possibly be related to corrosion of metal parts that were accidently introduced to the completion zone during drilling, but no

plausible explanation could be found for the increase of major ions such as sodium, alkalinity, or sulfate in well MW-14D.

9.2.5.8. Deep Groundwater Samples

A set of groundwater samples was collected from exploration borehole DH-8417 (Figure 9.2-1) in the summer of 2008. This borehole was located in the Pebble East area and reached a depth of 4,050 feet. Airlift pumping tests were conducted in DH-8417 as drilling progressed, and pressure response was measured in DH-6349, which was located about 100 feet away. Near the end of each pumping test in DH-8417, one or several samples were collected for water quality analysis. Pumped volumes ranged from 9.6 to 17.5 borehole volumes above a depth of 2,350 feet and from 1.5 to 4.2 borehole volumes below a depth of 2,350 feet (Table 9.2-4). Therefore, the samples above 2,350 feet are generally expected to be more representative of the groundwater chemistry because of the higher pumped volume. Because the samples were collected by airlifting, the measured pH was likely quite different than the in-situ pH due to the associated oxygenation associated with airlifting. Similarly, the concentrations of the major ions were probably more representative than the trace metals and trace elements, because the major ions would be less sensitive to mineral precipitation as a result of oxygenation. Twenty water quality samples were collected from eight depth intervals ranging from 640 to 4,050 feet at DH-8417 (Table 9.2-4). Eight samples were primary samples and 12 were QC samples (duplicates and blanks).

As shown on the Piper plot (Figure 9.2-23), the shallowest sample from interval 640 to 950 feet had a calcium-bicarbonate water type, which means that the dominant cation was calcium and the cominant anion was bicarbonate. All deeper samples below this interval had a calcium-sodium-sulfate water type. The sodium content ranged from 50 to 65 percent and the sulfate content was 80 percent or higher. Concentrations generally increased with depth down to 2,000 or 3,000 feet, depending on the parameter (Figures 9.2-23 and 9.2-24a through 9.24c). The depth over which the concentrations increased generally correlated with the depth of the fault contact between the Tertiary bedrock and the mineralized bedrock. TDS increased noticeably down to a depth of about 2,000 feet and stabilized below this depth at concentrations between 1,700 mg/L and 2,500 mg/L. The depth trend for sodium, magnesium, sulfate, and chloride was similar to TDS. The magnesium concentration peaked at about 25 mg/L at a depth of 3,000 feet, then decreased again to about 15 mg/L at a depth of 4,000 feet. Alkalinity had a maximum concentration of 130 mg/L in the shallowest sampling interval and had concentrations that varied randomly between 50 and 90 mg/L at greater depths, which contrasted with other parameters. The pH decreased from a maximum of 8.4 in the shallow depths to a minimum of 7.3 at the deeper depths of the borehole. However, as discussed earlier, because the samples were collected by airlifting, the measured pH was probably affected by the associated oxygenation and probably did not represent the in-situ pH. Consequently there were no valid pH data collected at depth. Among the minor ions and metals, lead, molybdenum, thallium, and arsenic concentrations peaked between 2,500 and 3,500 feet, and decreased again at greater depth. The concentrations of minor ions and metals were probably more affected by the airlift sampling than the major ions, and the depth trends of these minor elements were likely less representative than the major ions. Nevertheless, similar to the major ions, the concentrations of minor ions and metals were higher below the fault contact between the Tertiary bedrock and the mineralized bedrock.

The composition of the deep bedrock ground water samples was different from most shallow ground water samples (Figure 9.2-25). Three of the shallow bedrock nests approached the composition of the

deep bedrock samples, but all nests completed in overburden were distinctly different. With respect to the major cations, the deep bedrock ground water samples had proportionally less magnesium and more sodium. With respect to the major anions, all but one of the deep bedrock ground water samples was strongly dominated by sulfate (80 percent or greater), whereas all but one of the shallow samples contained less than 60 percent sulfate. In summary, one deep bedrock ground water sample had a water type of calcium-bicarbonate and all other deep samples were of type sodium-sulfate. Of all the shallow wells, PQ4 had a composition that was most similar to the deep samples and was of type calcium-sulfate. Wells P4S, MW-14D, and SRK5D were the next most similar samples.

The type of relationship between the concentration of a particular constituent and TDS depended on the constituent. The concentrations of some constituents increased linearly as a function of TDS for both shallow and deep samples. This behavior was observed for sulfate (Figure 9.2-26a), fluoride (Figure 9.2-26a), potassium (Figure 9.2-26c), and somewhat for molybdenum (Figure 9.2-26b). The second class of parameters showed a different behavior for samples in shallow and deep groundwater, and could not be approximated by a common line. Parameters in this category included chloride, magnesium, mercury, and zinc. For cases where concentrations increased proportionally in both deep and shallow samples, a common mineral dissolution process likely controlled the concentrations of these constituents. These constituents probably accumulate steadily in the groundwater as it reaches greater depths. For example, the dissolution of fluorite is likely the only process contributing fluoride to the groundwater. The concentration of this parameter increased as the TDS increased with the dissolution of other more soluble minerals. Conversely, the concentration of parameters that increase differently as a function of TDS in shallow and deep groundwater is likely controlled by different processes as a function of depth. For example, calcium and magnesium concentrations were likely controlled by the dissolution of the relatively soluble carbonates in the shallow wells but may have been controlled by dissolution of less soluble silicates in the deep bedrock. In contrast, chloride had very low concentrations in the shallow wells due to the lack of a subsurface source. Due to the extended residence time and the slightly elevated temperature, the groundwater in the deep bedrock seemed to leach chloride from minerals that would not dissolve under near-surface conditions.

Conversely, some parameters in the shallow wells had higher concentrations than in the ground water in the deep bedrock. For example, barium, zinc, and particularly mercury had some ground water concentrations that were higher in the shallow wells than in the deep bedrock wells, suggesting that the respective minerals were more abundant in the shallow zone (Figures 9.2-26b and 9.2-26c). Most of the shallow wells that had concentrations greater than the deep bedrock ground water samples were located close to the general deposit area, including SRK3, SRK2, MW-12S, and SRK5S. Well MW-14D also had parameters with concentrations greater than the deep bedrock ground water samples but was located about 4 miles south of the general deposit area.

9.2.6. Summary

In general, the groundwater within the mine study area was mostly characterized by TDS less than 100 mg/L (comparable to surface water), pH between 5.8 and 7.4, DO greater than 10 mg/L, and trace metals below the most stringent ADEC water quality criteria. The groundwater was divided into three general classes based on TDS: high TDS close to the general deposit area, intermediate TDS at intermediate distances from the general deposit area, and low TDS at greater distances from the general deposit area. The wells with the highest proportion of sulfate were located closest to the general deposit

area, suggesting the groundwater in this area is influenced by sulfide oxidation (Figures 9.2-3 and 9.2-4). Eight of the wells (six completed in overburden, two in bedrock) had median pH values greater than 7.0, and three of these wells (all completed in overburden) have the highest TDS concentrations (Figures 9.2-3 and 9.2-4; Table 9.2-3). Eight wells (five completed in overburden, three in bedrock) had pH median values less than 6.0. Of the wells completed in overburden, these eight wells contained among the lowest median TDS concentrations and had major-ion compositions with less than 50 percent sulfate in all but one sample (Figure 9.2-3). Therefore, these relatively low pH values are most likely due to equilibrium with atmospheric carbon dioxide (CO_2) in the absence of pH-buffering minerals rather than sulfide oxidation. This interpretation is consistent with the shallow depths of these wells.

Except for 12 wells (three in overburden and nine in bedrock), median DO concentrations were 5 mg/L or greater, which suggests that the aquifer solids in most areas of the site do not include abundant reducing agents such as organic carbon or sulfide minerals. Short groundwater transit times through the aquifers may also help to maintain high DO concentrations. Eight of these 12 wells had DO concentrations less than 1 mg/L, and three of these wells had the highest TDS (Table 9.2-3). Although many wells within the study area have oxic groundwater, and sulfides appear to be oxidizing in at least some parts of the general deposit area, both the correlation between low DO and high TDS and relatively high iron and manganese suggest that some occurrences of high TDS might be due to oxidation of sulfides.

The wells with high TDS also generally had relatively high concentrations of arsenic, barium, and molybdenum compared with other wells in the study area (Table 9.2-3). All of the wells with more than two trace metals at relatively high concentrations were located closer to the general deposit area. The wells that were located further from the general deposit area mostly had relatively low trace metal concentrations (Table 9.2-3). Well PQ4 had the most trace metals (nine) at relatively high median concentrations. Although some wells had trace metal concentrations that were higher than other wells, very few samples were higher than the most stringent ADEC maximum criterion.

Several wells had decreasing concentrations over time early in the sampling record, indicating that the geochemistry around the well was equilibrating during that time. Well MW-14D is the only well that had a large number of parameters with concentrations that increased year to year throughout the sampling record.

The TDS of deep groundwater samples collected from borehole DH-8417 at eight depth intervals ranging from 640 to 4,050 feet increased with depth. Most of the samples collected at greater depths were of type sodium-calcium-sulfate and reached a TDS of 2,000 mg/L. The concentrations of some constituents in the overburden and shallow bedrock ground water wells were similar to the concentrations of the deep bedrock ground water samples.

	9	D (201)	Bedrock Contact
P-06-38	4	M (62)	Bedrock Contact
	1	D (170)	

Nest	Total Number of Samples Collected [a]	Completions [b, c] (feet)	Lithology
DH-8417	3	B(640-795)	Deep Bedrock
	2	C(950-1,470)	Deep Bedrock
	1	E(1,900-2,350)	Deep Bedrock
	2	F(2,356-2,900)	Deep Bedrock
	2	G(2,900-3,300)	Deep Bedrock
	1	H(3,300-3,700)	Deep Bedrock
	1	I(3,700-4,050)	Deep Bedrock

Notes:

a. The timing of sample collection is documented in the Period of Record Index, which is included in the Field Sampling Plan (Appendix G of the Environmental Baseline Document).

b. D = deep, M = medium, S = shallow.

c. Numbers in parentheses are depths, in feet, to bottom of well below ground surface; the screen length is typically 10 feet.

TABLE 9.2-2
Frequency of Detection and Method Detection Limit by Parameter for Groundwater Samples, Mine Study Area, 2004-2008

Parameter	Unit	MDL				# Samples	Frequency of Detection
		Minimum	Maximum	Median	95th Percentile		
Alkalinity	mg/L	3.1	6.2	3.1	6.2	523	97
Aluminum	µg/L	0.07	7.8	0.62	0.62	489	57

Key: Ag = silver; Al = aluminum; Alk = alkalinity; As = arsenic; Ba = barium; Be = beryllium; Ca = calcium; Cd = cadmium; Cr = chromium; Cu = copper; DO = dissolved oxygen; Fe = iron; Hg = mercury; K = potassium; Mg = magnesium; Mn = manganese; Mo = molybdenum; Na = sodium; Ni = nickel; Pb = lead; Sb = antimony; Se = selenium; SO4 = sulfate; TDS = total dissolved solids; Tl = thallium; V = vanadium; and Zn = zinc.

TABLE 9.2-4
Sampled Intervals in Deep Borehole 8417, Mine Study, 2004-2008

Depth (feet bgs)	Date	Borehole Volumes Pumped	Sample Collected	TDS (mg/L)
205-640 [a]	6-Jul-08	11.5	No	
640-950	13-Jul-08	9.6	Yes	155
950-1470	23-Jul-08	9.9	Yes	452
1470-1900 [b]	17-Aug-08	0.4	No	
1900-2350	23-Aug-08	17.5	Yes	1860
2356-2900	4-Sep-08	2.5	Yes	1760
2900-3300	10-Sep-08	3.9	Yes	2370
3300-3700	15-Sep-08	4.2	Yes	2030
3700-4050	21-Sep-08	1.5	Yes	985

Notes:

a. Sample not collected. Field EC=253 and pH=7.06

b. Sample not collected due to low pumping volumes

Key:

bgs = below ground surface.

mg/L = milligram per liter.

APPENDICES

APPENDIX 9.2A

Groundwater Field Parameter Data at Individual Well Locations, Mine Study Area 2004-2008

APPENDIX 9.2A
GROUNDWATER FIELD PARAMETER DATA AT INDIVIDUAL WELL LOCATIONS, MINE STUDY AREA (2004-2008)

Appendix 9.2A Groundwater Field Parameter Data at Individual Well Locations, Mine Study Area (2004-2008)

Table of Contents

Field Parameter Data for the Following Groundwater Monioring Well Locations:
MW-1S, MW-1M, MW-1D, MW-2D 1
MW-3D, MW-5S, MW-5M, MW-5D 2
MW-6D, MW-7S, MW-7D, MW-8S.....3
MW-8M, MW-8D, MW-9D, MW-10, MW-11SS 4
MW-11S, MW-11M, MW-11D, MW-12S, MW-12D 5
MW-13S, MW-13D, MW-14S, MW-14D, MW-15D, KP-P4 6
PQ-4, P-4S, SKR-2, SRK-3, SRK-5S 7
SRK-5M, SRK-5D, P-06-37S, P-06-37M, P-06-37D,
P-06-38M, P-06-38D.....8

Key

1. ORP = Oxidation Reduction Potential
2. Temp = Temperature
3. MW7S: example of monitoring well station label
   The S, M and D suffix in the station label indicates the relative depth of the installation.
   - S: shallow
   - M: medium or intermediate
   - D: deep
4. mg/L = milligram per liter
5. µS/cm = microsiemens per centimeter
6. mV = millivolts
