## ADF\&G TECHNICAL DATA REPORTS

This series of reports is designed to facilitate prompt reporting of data from studies conducted by the Alaska Department of Fish and Game, especially studies which may be of direct and immediate interest to scientists of other agencies.

The primary purpose of these reports is presentation of data. Description of programs and data collection methods is included only to the extent required for interpretation of the data. Analysis is generally limited to that necessary for clarification of data collection methods and interpretation of the basic data. No attempt is made in these reports to present analysis of the data relative to its ultimate or intended use.

Data presented in these reports is intended to be final, however, some revisions may occasionally be necessary. Minor revision will be made via errata sheets. Major revisions will be made in the form of revised reports.

## ABSTRACT

Linear discriminant function analysis of scale pattern of age 52 and age 42 sockeye salmon (Oncorhynchus nerka) sampled from the escapements and from the commercial harvest of Upper Cook Inlet, Alaska provided the basis for apportioning the catch into component stocks. The five component stocks are: Susitna River, Kenai River, Kasilof River, Crescent River, and Fish Creek. The total return of sockeye salmon to Upper Cook Inlet in 1979 was estimated to be $1,658,640$, of which 923,518 ( $55.7 \%$ ) were harvested and 735,122 escaped to spawn. The total return and exploitation rates for the principal stocks contributing to the return were: Kenai River 597,884 (0.525); Kasilof River 442,893 (0.675); Susitna River 376,831 (0.583); Crescent River 123,454 (0.339); and Fish Creek 117,578 (0.584).

## INTRODUCTION

Upper Cook Inlet encompasses the marine waters north of Anchor Point (Figure 1) and is divided into two fishing districts, the Northern and Central. Within these districts eight distinct fisheries can be identified. In the Northern District there are two set net beach fisheries: the Northern District East-side and Northern District West-side. In the Central District there is a drift net fishery and six set net beach fisheries; Salamatof Beach, Kalifonsky Beach, Cohoe/Ninilchik Beach, Kalgin Island East-side, Kalgin Island West-side, and the Central District West-side.

In Upper Cook Inlet, commercial harvests of sockeye salmon (Oncorhynchus nerka) have averaged 1.1 million fish in the last 10 years. The major producers of sockeye salmon in Upper Cook Inlet are the Kenai, Susitna, and Kasilof Rivers, followed in magnitude by the Crescent River and Fish Creek (outlet stream of Big Lake). Several other systems are known to produce smaller runs of sockeye salmon (Namtvedt et al. 1978).

The commercial fishery in Upper Cook Inlet harvests mixed stocks of sockeye salmon. Estimation of the numbers of fish harvested by stock is essential to sound management. Catch apportionment by stock coupled with escapement estimates provides estimates of total return by brood year. Total return estimates can subsequently be used to model spawner-recruit relationships, to estimate optimum escapements, and to forecast returning run size. Finally, the knowledge of the distribution and relative abundance by stock allows the fishery manager to protect and/or selectively harvest individual stocks.

Previous investigations in Upper Cook Inlet have documented the feasibility of using scale pattern recognition techniques as a method of identifying the various sockeye salmon stocks (Bethe and Krasnowski 1979; Bethe, Krasnowski, and Marshall 1980). The purpose of this study is to provide estimates of the 1979 return by stock of sockeye salmon of Upper Cook Inlet.

While several minor stocks contribute to the annual harvest (Namtvedt et al. 1978) we have no data which will permit allocation. The reader should remain cognizant that all fish harvested were allocated to one of the five principal stocks, making these estimates somewhat liberal.

METHODS

## Numbers of Fish

Estimation of the numbers of fish returning to Upper Cook Inlet requires that both catch and escapement numbers be derived. Compilation of catch statistics is facilitated by the State of Alaska's fish ticket program. Estimation of escapement to the rivers of Upper Cook Inlet is complicated by turbid waters. In most cases hydroacoustic techniques provide estimates of escapement.

Figure 1. The Upper Cook inlet area showing the locations of the Northern and Central Districts and the maior sockeye salmon spawing drainages.

Catch:
Catch statistics reported in this paper represent the total number of sockeye salmon harvest in each fishery by date according to Alaska Department of Fish and Game preliminary fish ticket summaries as of October 1980.

Escapement:
Sockeye salmon escapements into the Susitna, Kenai, Kasilof, and Crescent Rivers were enumerated by Bendix sonar salmon counters. Two side scanning sonar adult counters (one on each river bank) were employed at each of the Susitna, Kenai, and Kasilof Rivers. At the Crescent River one side scanning counter and one 1974 model multiple transducer counter was operated. Sonar units were located on the Susitna River approximately 25 mi upstream from the mouth and operated from 1 July through 29 August 1979. Sonar units on the Kenai River were located 15 mi upstream of the river mouth and enumeration of the late run of salmon occurred from 22 June through 14 August. The late salmon run into the Kasilof River was counted from 22 June through 13 August by sonar counters installed 17 mi upstream. Escapement into the Crescent River was monitored from 1 July through 12 August with sonar counters situated 20 mi upstream of the river mouth. Fishwheel catch data was used to apportion sonar counts for each salmon species on the Susitna, Kenai, and Kasilof Rivers. On the Crescent River trip seine catch data was used for apportionment of sonar counts. Methods used in 1979 for the installation and operation of the sonar counters were similar to those used in 1978 and are documented by Waltemyer et al. (1980). Escapement into Fish Creek was enumerated by means of an adult salmon weir located approximately 0.5 mi upstream of the river mouth. The design and operation of the weir is detailed by Chulpach (1979).

## Age Composition

Sockeye salmon ages were determined through examination of scale samples. Scales were collected from the preferred area of the fish which is on the left side of the body two rows above the lateral line in the diagonal scale row downward from the posterior edge of the dorsal fin (INPFC 1961). Scales were mounted on gum cards and impressions made in cellulose acetate (Clutter and Whitese 1956). Ages were recorded in Gilbert-Rich ${ }^{1}$ notation.

Commercial Catch Samples:
Scales were collected from the commercial fisheries each fishing period from 22 June until 27 July. We attempted to collect 200-250 samples per fishing period from each of the nine fisheries. Catch samples were taken at local fish processing plants for the following fisheries: Northern District East-side, Northern District West-side, Central District Drift,

[^1]Central District West-side, Kalgin Island East-side, and Kalgin Island West-side. Samples were taken directly from set net sites along Salamatof, Kalifonsky, and Cohoe/Ninilchik beaches. Scales were taken, length (mideye to fork of tail) measured, and sex recorded for fish sampled at the processing facilities. Only scales were taken from fish sampled along the beaches in order to reduce collection time and allow more fish to be sampled.

Age composition estimates for each fishery were computed by fishing dates. For those dates in which scale samples were not taken for a particular fishery, the age composition estimates of the nearest date for the same fishery were applied to the catch in question.

Escapement Samples:
Sockeye salmon returning to five river systems were sampled for sex, length (mid-eye to fork of tail), and for scales. Fish were collected from the Susitna, Kenai, and Kasilof Rivers by fishwheels which operated at the sonar enumeration site on each of the rivers. Additionally, sockeye salmon were collected from the Kenai River from 29 June through 5 July by fishing two 10 fm variable mesh gill nets and one $30 \mathrm{fm} 5 \frac{1}{4}$ " mesh gill net approximated 13 mi upstream of the river mouth.

Crescent River fish were collected by a trip seine operated at the sonar location, with the exception of samples taken on 6 July and 7 July which were collected with a $30 \mathrm{fm} 5 \frac{1}{4}$ " mesh gill net.

The number and periodicity of scale samples from each river varied, however, the first 300 sockeye salmon captured at each river were sampled. After this initial sample, efforts were reduced to sampling a maximum of 40 fish per day from each river.

Age composition estimates for the Susitna, Kenai, Kasilof, and Crescent Rivers were calculated by time periods. Three time periods were used: period 1 that included scale samples collected from 22 June through 10 July; period 2 included scale samples taken from 11 July through 22 July; and period 3 included scale samples collected after 22 July.

Age composition estimates for Fish Creek were computed over the entire sampling period which extended from 11 July through 12 August.

## Stock Identification

Estimates of the proportion of the catch by district originating from each stock were made utilizing discriminant function analysis of scale patterns or age composition information. In this section we explain each technique and elaborate how each method was implemented on a district by district basis.

Scale Measurements:
Scale impressions were projected at 100X magnification using equipment similar to that described by Bilton (1970) and later modified by Ryan and

Christie (1976). Measurements were taken along an axis which is approximately $20^{\circ}$ off the primary axis and perpendicular to the sculptured field. Age 42 and age 52 scales taken from Susitna, Kenai, and Kasilof escapements were measured. Age 42 scales collected from Fish Creek's escapement and age 52 scales sampled from the Crescent River escapement were measured. The age class analyzed from each commercial catch depended upon which age class was dominant. Age 42 scales were measured from the fisheries in the Northern District and from the Central District drift. Age 52 scales were measured from all the fisheries in the Central District.

The variables measured from age 52 scales and entered into the discriminant analysis procedure are diagrammed in Figure 2. The variables measured from age 42 scales were identical to those measured from age 52 scales with the exception that only the first ocean zone was measured on age 42 scales.

## Discriminant Function Analysis:

Linear discriminant function analysis (Fisher 1936; Nie et al. 1975) of scale measurements was used to identify the origin of sockeye salmon sampled from the commercial fisheries. Stepwise discriminant function analysis was used and the F level set at 1 . Whichever variables were accepted by stepwise procedure were used in the analysis.

Scale measurement from fish of known origin sampled from the escapements were used as standards to build the classification models, i.e., the discriminant functions. A second discrete sample from each of the escapements was classified by the discriminant functions and estimates of accuracy and misclassification were calculated. The standard and test samples representing each escapement were interchanged and a second associated classification model was built and tested. The classification accuracy estimates of the two associated models were averaged to determine the final overall classification accuracy.

Scale measurements from fish of unknown origin, i.e., commercial catch samples, were classified and stock composition estimates of each catch estimated. Stock estimates were corrected for misclassification error rates using the procedures of Cook and Lord (1978). The variance and $90 \%$ confidence intervals were computed using the methods of Pella and Robertson (1979). Catch samples were classified by each of the associated identification models. Corrected stock estimates were averaged to produce the final stock estimates and $90 \%$ confidence intervals.

Age 52 Analyses:
A four-way stock identification model was constructed from age 52 scale measurements representing Susitna, Kenai, Kasilof, and Crescent Rivers. All commercial catch samples from the Central District were classified with the four-way model and estimates of stock proportions for the 52 age class developed. A catch sample was reclassified with a model representing fewer stocks if the final proportion estimate or the estimate's lower

Figure 2. Age $5_{2}$ sockeye salmon scale showing scale characteristics used in discriminant analysis.
boundary of the $10 \%$ confidence interval was less than or equal to zero for the stock in question.

Age 52 proportion estimates for the Central District fisheries were calculated by fishing period with the exception of Kalgin Island's fisheries. One age 52 stock estimate for the entire season was computed for each of the Kalgin Island East-side and the Kalgin Island West-side fisheries.

Age 42 Analyses:
Age 42 scale patterns were analyzed so that the contribution of Fish Creek to the Northern District and Central District drift harvests could be examined.

A four-way stock identification model was constructed from age 42 scale measurements representing Susitna, Kenai, Kasilof, and Fish Creek stocks. The ability of this model to correctly classify Susitna and Kenai fish was low, $44 \%$ and $73 \%$ respectively; while classification accuracy for Fish Creek (96\%) was high. Because of the poor separability between Susitna and Kenai scale patterns and the distinctiveness of Fish Creek scales, we decided to pool Susitna, Kenai, and Kasilof stocks into a single category for further analyses.

We made the assumption that Kasilof River stocks did not contribute significantly to the Northern District set net catches. Northern District catch samples were classified with a two-way model which included Fish Creek as one category and combined Susitna and Kenai stocks as the other category. Stock estimates were calculated for Northern District East-side and Northern District West-side catches for two time periods, 2 July through 13 July and 16 July through 27 July.

Susitna, Kenai, and Kasilof measurements were pooled as one category and Fish Creek scale measurements made up the other category of the two-way model used to classify Central District drift catch samples. Age 42 stock estimates were calculated from Central District drift catch samples representing two time periods, 25 June through 9 July and 13 July through 22 July.

Catch Apportionment:
Each fishery of Upper Cook Inlet poses unique problems in catch apportionment. Differences exist in the contributing stocks, in age composition of the catch, and in the power of discriminant models to identify the various possible stock mixtures. In this section we present the specific techniques used to apportion the catch on a district by district basis.

Central District Set Net Fisheries. Sockeye salmon catches from the Central District set net fisheries were apportioned by age class and river system. Catch apportionment figures are based upon a combination of scale analysis and age composition techniques. Scale pattern analysis was used to estimate the proportions of age $5_{2}$ fish in the Central District set net catch by river system. Allocation by stock of the other age classes was based upon age 52 stock estimates and the ratios of the proportion of each age class to the 52 age class from the respective escapements. An age $5_{2}$ stock estimate for a given catch was expanded to estimate the stock proportion for another age
class using the following formula:

Where:

$$
\begin{aligned}
\hat{S}_{i j}= & \text { Estimated proportion of stock } i \text { to the harvest } \\
& \text { of age } j .
\end{aligned}
$$

$A_{i j}=$ Proportion of age $j$ in stock $i$ 's escapement.
$A_{i 5_{2}}=$ Proportion of age $5_{2}$ in stock i's escapement.
$N=$ Number of stocks.

Migration times were added to catch dates when calculating age class ratios in the rivers so that the escapement composition would best represent the population of fish being harvested earlier by the fishery. The age class ratios applied to a specific catch on date $K$ equaled the proportion of age classes observed in the river on date K plus migration time. The estimated number of days from the mouth of each river to its counting site is: Susitna 6 days, Kenai 1-2 days, Kasilof 1-2 days, and Crescent 10 days (Bruce King, Dave Waltemyer personal communication). To calculate the additional migration time from the fishery to the river mouth we used a migration rate of 20 miles per day (Dahlberg 1968; French et al. 1976). The migration times used from the fisheries to each of the river's counting sites can be found by referring to Table 23.

Central District Drift Net Fisheries. Central District drift net sockeye salmon catches were also apportioned by age class and river system. Methods used to apportion the drift catch to Susitna, Kenai, and Kasilof Rivers were similar to those outlined above.

Scale pattern analysis was also used to estimate the proportion of the 42 catch of Fish Creek origin. The allocation of Fish Creek stocks for the other
age classes was calculated by the following formula:

$$
\hat{N}_{j}=\left(\hat{N}_{4_{2}}\right)\left(P_{4_{2}} / P_{j}\right)
$$

Where:

Migration times were not added to catch dates when applying the age class ratios because the age composition data for Fish Creek was not calculated by date.

Northern District Set Net Fisheries. Northern District East-side and Northern District West-side set net sockeye salmon harvests were apportioned by age class and river system. Scale pattern analysis was used to estimate the proportion of the 42 catch contributed by Fish Creek. Methods used to allocate the contribution of Fish Creek to the other age classes were similar to those used for the Central District drift net catch described above. Northern District set net catches were apportioned to the Susitna and Kenai Rivers by comparing the age composition of the catch with that of the escapements through time.

The formula used to estimate the catch by stock for one age class and one fishery is:

$$
c_{i j}=c_{i .} \times \frac{E_{j}}{T_{e}}
$$

where:

$$
\begin{aligned}
& C_{i j}= \text { catch of the age class in question from river system } j \\
& \text { on day } i
\end{aligned}
$$

Rather than using a single annual stock proportion by age class $\left(\frac{E_{j}}{T_{e}}\right)$ stock proportions were calculated through time. The Northern District e set net catches were broken into five time periods: 25 June through 1 July, 2 July through 8 July, 9 July through 15 July, 16 July through 22 July, and all catch dates after 22 July. The migration times from the fisheries to the Susitna and Kenai counting sites were added to the catch dates. This resulted in five corresponding time periods for each of the escapements. Migration times used were: Susitna 8 days and Kenai 3 days. Stock proportions by age class were calculated for each of the five time periods. Numbers of fish by stock for a time period equaled the total escapement into each river during the corresponding lagged escapement time period. Age class proportions calculated from scale data were applied to these numbers to estimate numbers of fish by age class for each river. Fish by age class by river were summed and stock proportions by age class and time period developed.

## Total Return

Estimation of total return on a daily basis requires that catches by stock be combined with escapement estimates. Migration time was taken into account by adjusting all catch dates to correspond with escapement dates.

RESULTS

## Number of Fish

This section summarizes the numbers of fish harvested by district and in the spawning escapement to each river. The reader should remain cognizant that in this report we were only able to address the contribution of the principal runs of sockeye salmon. Assessment of the contributions of minor stocks is not possible at this time.

Catch:
A total of 923,518 sockeye salmon was harvested in Upper Cook Inlet in 1979 (Table 1). Almost one-half of these ( 454,428 or $49.2 \%$ ) were taken by the

${ }^{1}$ Catch figures were summarized from preliminary Alaska Department of Fish and Game statistics as of 7/16/80.

Central District drift net fleet. The Central District East-side set net fisheries accounted for $26.9 \%$ of the harvest. The remaining $23.9 \%$ of the harvest was taken in the Northern District and by the West-side set net fisheries.

Escapement:
The estimated total escapement of the principal sockeye salmon stocks in Upper Cook Inlet in 1979 was 735,122 . The numbers by principal river systems can be found in Table 2. The escapements of sockeye salmon to these systems were: Kenai River 283,880; Susitna River 157,000; Kasilof River 143,920; Crescent River 81,600; and Fish Creek 68,722.

## Age Composition

Significant differences in age composition are evident for the various river's escapement. Differences are also evident between many of the fishing districts. Age data, by themself have provided insights to stock composition of catches during the fishing season.

Escapement Samples:
The number of sockeye salmon sampled in the escapement to Susitna River, Kenai River, Kasilof River, and Crescent River are shown by date, age class, and sex in Tables 3-6, respectively. In Table 7 we show the age composition of the escapement by stock and period.

In the Susitna River age 42 sockeye predominated ( $61.0 \%$ ) and age 52 's comprised $20.6 \%$ (Table 7). In the Kenai River age 52 sockeye were the most abundant ( $61.1 \%$ ) followed by age 42 fish ( $20.2 \%$ ). In the Kasilof River age 42 sockeye were more common than age 52 ( $52.2 \%$ vs $37.2 \%$, respectively). The Crescent River exhibited a preponderance of age 52 sockeye ( $70.1 \%$ ) followed by age 42 sockeye $27.8 \%$. In Fish Creek most ( $90.0 \%$ ) sockeye were age 42 .

Commercial Catch Samples:
Age composition of the commercial catches by district and date are shown in Tables 8-16. Age 52 sockeye salmon comprised $45.9 \%$ of the total catch, age $4236.6 \%$, age $5311.6 \%$, age $634.4 \%$, and others $1.5 \%$.

## Stock Identification

In this section we summarize the pertinent data which were used to make final estimates of the contribution of each stock to the commercial harvest of sockeye salmon in 1979. Estimates of classification accuracy and confidence coefficients for the age specific stock composition estimates are of particular importance since these factors define the power of the analysis.

Summary Statistics for Scale Measurements:
Summary statistics for variables measured from scale samples of age 52 and 42 sockeye salmon are shown in Tables 17 and 18, respectively. Summary

Table 2. Sockeye salmon escapement by date and system, Upper Cook Inlet, $1979^{1}$.

${ }^{1}$ Susitna River escapement figures represent final apportioned sonar counts rounded to the nearest 100 fish. Kenai River and Kasilof River escapement figures represent final apportioned sonar counts to the nearest fish. Crescent River escapement figures represent final apportioned sonar counts combined with visual counts rounded to the nearest 100 fish. Fish Creek escapement figures represent weir counts.

Table 3. Age and sex composition of sockeye salmon sampled from the Susitna River, Upper Cook Inlet, 1979.

${ }^{1}$ Figures represent the percent of each age class which are males and females, and the percent each age class represents of the total sample for the time period.

Table 4. Age and sex composition of sockeye salmon sampled from the Kenai River, Upper Cook Inlet, 1979.

${ }^{1}$ Figures represent the percent of each age class which are males and females, and the percent each age
class represents of the total sample for the time period.

Table 5. Age and sex composition of sockeye salmon sampled from the Kasilof River, Upper Cook Inlet, 1979.

${ }^{1}$ Figures represent the percent of each age class which are males and females, and the percent each age class represents of the total sample for the time period.

Table 6. Age and sex composition of sockeye salmon sampled from the Crescent River, Upper Cook Inlet, 1979.

${ }^{1}$ Figures represent the percent of each age class which are males and females, and the percent each age class represents of the total sample for the time period.

1 Scales were not collected prior to $7 / 02$, age composition estimates from 7/02 were applied to the total catch made prior to 7/02.

2 Scales were not collected on $7 / 06,7 / 09$, or $7 / 13$. Age composition estimates from 7/02 and 7/16 were averaged and the average figures used as age composition estimates for $7 / 06,7 / 09,7 / 13$.

3 Scales were not collected after 7/27. Age composition estimates from $7 / 27$ were applied to the total catch made after 7/27.

statistics are provided regardless of whether or not the variable was used in subsequent discriminant analysis. These data show that the largest relative differences in scale patterns between stocks are found in the freshwater growth zones. Relative differences between stocks in the ocean growth zones are less pronounced.

Classification Accuracy:
Table 19 summarizes the 4-way, 3-way, and 2-way test classification matrices generated from the discriminant analysis of age 52 sockeye salmon. Table 20 shows similar data for age 42 sockeye salmon.

Average overall classification accuracy for all 4-way, 3-way, and 2-way classification models for age 52 fish was $67.9 \%, 75.9 \%$, and $81.7 \%$, respectively. Susitna River stocks typically showed the poorest classification accuracy and Crescent River stocks the best. Kenai and Kasilof stocks were intermediate in accuracy and very similar.

The ability of scale patterns to identify the origins of age 42 fish was in general poorer than that for age 52 fish. The exception being that the Fish Creek stock is quite unique; the models were able to correctly identify better than $95 \%$ of these fish.

## Age Specific Stock Composition Estimates:

Stock composition estimates and $90 \%$ confidence coefficients by subdistrict for the Central District based on scale patterns of age 52 sockeye salmon are shown in Table 21. In Table 22 we show stock composition estimates and $90 \%$ confidence coefficients for the Northern District and Central District drift net fleet based on scale patterns of age 42 sockeye salmon.

Confidence coefficients for age specific stock composition estimates based on scale pattern analysis of age 52 sockeye salmon typically fell within the range of 0.1 to 0.3 . Confidence coefficients based on an analysis of age 42 fish were less than 0.10 .

Migration Rates:
Estimates of the migration time, in days, from each fishery to each contributing river's enumeration and sampling site is shown in Table 23. These data suggest that Susitna River, Crescent River, and Fish Creek stocks require a substantial amount of time to travel from the various fisheries of Upper Cook Inlet to the Department's enumeration and sampling sites. Migration times for the Kenai River and Kasilof River stocks are, on the contrary, much shorter.

## Catch Apportionment

This section summarizes estimates of the contribution of each stock to the commercial harvest of sockeye salmon to the commercial harvest of sockeye salmon in 1979. Estimates are provided by age class and date for each fishery.

In addition, a summary table provides estimates of the total catch by stock and fishery.

Regulatory District Summary:
Estimates of the number of fish by stock and age contributing to each fishery by date is shown in Tables 24-32.

In the Northern District East-side set net fishery (Table 24), 60,912 sockeye salmon were harvested of which: $51.6 \%$ were Kenai River, $30.3 \%$ Susitna River, and $18.1 \%$ Fish Creek.

In the Northern District West-side set net fishery (Table 25) 51,538 sockeye salmon were harvested of which $65.5 \%$ were Kenai River, $28.9 \%$ Susitna River, and 5.6\% Fish Creek.

In the Central District drift net fishery (Table 26), 454,428 sockeye salmon were harvested of which $34.1 \%$ were Kasilof River, $32.1 \%$ Kenai River, $26.1 \%$ Susitna River, and 7.7\% Fish Creek.

In the Central District West-side set net fishery (Table 27), 63,442 sockeye salmon were harvested of which $63.6 \%$ were Crescent River, $24.1 \%$ Susitna River, 8.5\% Kenai River, and 3.8\% Kasilof River.

In the Kalgin Island East-side set net fishery (Table 28), 16,714 sockeye salmon were harvested of which $70.4 \%$ were Kasilof River, $22.7 \%$ Kenai River, and 6.9\% Crescent River.

In the Kalgin Island West-side set net fishery (Table 29), 28,256 sockeye salmon were harvested, of which $64.0 \%$ were Susitna River, $18.9 \%$ Kenai River, and $17.1 \%$ Kasilof River.

In the Salamatof Beach set net fishery (Table 30 ), 80,401 sockeye salmon were harvested, of which $45.4 \%$ were Kenai River, $31.5 \%$ Kasilof River, and $23.1 \%$ Susitna River.

In the Kalifonsky Beach set net fishery (Table 31), 47,595 sockeye salmon were harvested of which $49.0 \%$ were Kenai River, $43.4 \%$ Kasilof River, $6.8 \%$ Susitna River, and 0.8\% Crescent River.

In the Cohoe/Ninilchik Beach set net fishery (Table 32), 120,232 sockeye salmon were harvested, of which $65.6 \%$ were Kasilof River, $23.8 \%$ Kenai River, and $10.6 \%$ Susitna River.

Stock Summary:
The total return of sockeye salmon to Upper Cook Inlet in 1979 was estimated at $1,658,640$ (Table 33), of which 923,518 ( $55.7 \%$ ) were harvested and 735,122 escaped to spawn.

The Kenai River's estimated total return of 597,884 accounted for $36.0 \%$ of total run to Upper Cook Inlet (Table 33). The majority of the Kenai River run ( $59.6 \%$ ) were age 52 fish. Age 42 comprised $20.7 \%$ of the return followed by age $53(12.5 \%), 63(6.6 \%)$, and all others ( $0.6 \%$ ). The exploitation rate for the Kenai River run was 0.525 . The Central District drift net fishery accounted for almost one-half ( $46.5 \%$ ) of the Kenai River run harvest (Table 34). Central District East-side set net fisheries accounted for $28.1 \%$ of the Kenai River run harvest. The Northern District accounted for 20.8\%. Few Kenai River fish were harvested on the west side of the Central District or on Kalgin Island.

The total return of sockeye salmon to the Kasilof River in 1979 was estimated at 442,893 , and accounted for $26.7 \%$ of the return to Upper Cook Inlet. Two principal age classes of sockeye salmon 42 ( $42.9 \%$ ) and 52 ( $40.1 \%$ ) comprised the total return (Table 33). The remaining fish were ages 53 (13.3\%), 63 (3.5\%), and others ( $0.2 \%$ ). The exploitation rate for the Kasilof River runs was 0.675 . The Central District drift net fishery accounted for $51.9 \%$ of the total harvest of 298,973 (Table 34). The Cohoe/Ninilchik Beach set net fishery took $26.4 \%$ of the Kasilof River harvest. We assumed that the Northern District did not intercept any Kasilof River fish. Most of the remaining harvest was taken on the other East-side set net fisheries.

The total return of 376,831 sockeye salmon to the Susitna River accounted for $22.7 \%$ of the total return to Upper Cook Inlet (Table 33). Susitna River sockeye exhibited the most variable age composition. Age 42 dominated ( $52.1 \%$ ), followed by ages $52(31.4 \%)$, others ( $7.7 \%$ ) , $53(7.0 \%)$, and $63(1.8 \%)$. The exploitation rate of the Susitna River run was 0.583 . The Central District drift net fishery accounted for over one-half ( $53.8 \%$ ) of the Susitna River run harvest (Table 34). The Kalgin Island East-side set net fishery was the only fishery which did not intercept Susitna River sockeye salmon. The remaining $46.2 \%$ of the Susitna harvest was spread out fairly equally between the remaining fisheries.

The total return of 123,545 sockeye salmon to Crescent River accounted for $7.4 \%$ of the return to Upper Cook Inlet in 1979. Age 52 sockeye predominated the return ( $70.6 \%$ ); age 42 accounted for $27.4 \%$ (Table 33 ). Ages 53 ( $0.9 \%$ ), other $(0.9 \%)$, and $\sigma_{3}(0.2 \%)$ composed the remainder of the return. The exploitation rate of the Crescent River run was 0.339. Essentially all ( $96.4 \%$ ) of the harvest was taken in the Central District West-side set net fishery (Table 34).

The total return of 117,578 sockeye salmon to Fish Creek accounted for $7.1 \%$ of the return to Upper Cook Inlet in 1979 (Table 33). Age 42 fish were the most abundant in the return accounting for $91.0 \%$. The remaining fish were age $52(2.0 \%), 53(1.0 \%)$, and other (5.9\%). The exploitation rate of this run was 0.584 . We estimated that the majority of these fish were harvested by the Central District drift fishery (71.5\%), the remaining harvest was in the Northern Districts (Table 34).

## Run Timing

In Tables 35-39 we summarized the daily and cumulative run of sockeye salmon to Upper Cook Inlet by stock. For each stock, the catches and escapements

Table 34. Summary of the catch by district and stock for sockeye salmon returning to Upper Cook Inlet in 1979.

${ }^{1}$ Dates represent escapement dates, i.e., the return of fish to the river counting site. Catch dates were adjusted to account for migration time to the river. Lag times used for each fishery to the Susitna River were: 11 days for Central District West-side and Central District drift; 10 days for Kalgin Island East-side, Kalgin Island West-side, and Cohoe/Ninilchik Beach; 9 days for Salamatof and Kalifonsky Beach; 8 days for Northern District East-side; and 7 days for Northern District West-side.

${ }^{1}$ Dates represent escapement dates, i.e., the return of fish to the river counting site. Catch dates were adjusted to account for migration time to the river. Lag times between each fishery and the Kenai River are: 3 days for the Northern District East-side, Northern District West-side, Central District drift, Kalgin Island East-side, Kalgin Island West-side, and Cohoe/Ninilchik Beach; 4 days for the Central District West-side; and 2 days for Salamatof and Kalifonsky Beach.

${ }^{1}$ Dates represent escapement dates, i.e., the return of the fish to the river counting site. Catch dates were adjusted to account for migration time to the river. Lag times used were: 11 days for the Central District drifts, 8 days for the Northern District East-side, and 7 days for the Northern District West-side.
have been combined by accounting for lag times between the various fishing districts and the escapement enumeration sites. In Table 40 we summarize the mean Julian date and the variance of the runs by stock. The return to the Kasilof River in 1979 was the earliest (mean $=192.9$ ) and also the most protracted (variance $=100.3$ ). The return to Fish Creek was the latest (mean $=204.9$ ) and also the shortest in duration (variance $=45.0$ ). Little difference in mean dates were evident for the Kenai River (199.6), Crescent River (202.0) or the Susitna River (203.7). The Crescent River did show a more protracted run (variance $=85.2$ ) than either the Kenai River (57.1) or the Susitna River (62.0).

Table 40. The mean date (Julian) and variance of the runs of sockeye salmon to Upper Cook Inlet, by stock, 1979.

| Stock | Mean | Variance |
| :--- | :---: | :---: |
| Susitna River | 203.7 | 62.0 |
| Kenai River | 199.6 | 57.1 |
| Kasilof River | 192.9 | 100.3 |
| Crescent River | 202.0 | 85.2 |
| Fish Creek | 204.9 | 45.0 |

## ACKNOWLEDGMENTS

The Upper Cook Inlet area management and research staff's provided much of the raw catch and escapement data presented in this report. In particular, we would like to acknowledge the assistance provided by Gary Sanders, Thomas Namtvedt, David Waltemyer, and Bruce King. Robert Chlupach of the F.R.E.D. Division provided escapement data and scale samples for Fish Creek.
