Preface

This report offers a description of Alaska's projected future population, based on historical data regarding Alaska's population size, and rates of fertility, mortality and migration. These projections serve as a reference work that provides planners and policy makers with outcomes of a series of demographic events.

It is important to note that Alaska is susceptible to many unpredictable events, and that no demographer or economist has a crystal ball to foresee the future. Though conditional estimates of uncertainty based on past data are provided for the state level projections, it is clearly not possible to predict what will happen.

Many thanks go to Brian Laurent, Research Analyst, and Jeff Hadland, Economist, for their careful review, and thoughtful comments and suggestions. Gratitude is further extended to Carl Mason and the Department of Demography at the University of California, Berkeley, for hosting class and laboratory presentations on Alaska's statewide population projections, and providing useful knowledge and feedback.

Special acknowledgment is given to the Vital Statistics sections of the Alaska Department of Health and Social Services, and the Alaska Departments of Revenue, and Commerce, Community and Economic Development for their aid in regularly providing information essential to the production of these projections. Special thanks also goes to the Alaska Department of Transportation and the Alaska Department of Health and Social Services for financial support during the production of these projections.

Comments or suggestions regarding the content or format of this publication are welcome. Many of the most requested statistics in this document may also be found on the Research and Analysis website at: <http://almis.labor.state.ak.us/>. Requests for demographic projections information may be addressed to Eddie Hunsinger, Research and Analysis Section, Alaska Department of Labor, P.O. Box 115501, Juneau, Alaska, 99811-5501. Telephone: (907) 465-5970; Fax: (907) 465-4506; email: eddie.hunsinger@alaska.gov.

Introduction

Alaska Population Projections

This report presents population projections for the State of Alaska, by age and sex, for the years 2007 through 2030. Additionally, 2010-2030 projections of Alaska's borough, census area, and Native populations, by age and sex, are presented.

Population projections are distinct from population estimates in that population estimates use current and historical data to make statements about the present and past, while projections use expected or extrapolated data to make statements about the future. There is much uncertainty in population projections, as it is not possible to predict future events, but projections based on reasoned assumptions are an important tool for planners and policy makers.

To create this set of population projections, a "cohort component" technique was used. Under this approach, the population of each sex is separated into age groups and aged forward in time, with projected births and in-migrants added, and projected deaths and out-migrants subtracted. The projection began with Alaska's 2005 population estimates and ended with the 2030 population projections. Technical details are provided in Appendix A at the end of the text.

Projections presented here are for the resident population of Alaska. The "July 1" projection dates represent an annual average population for each year, rather than the population on July 1. Seasonal populations may be higher than the annual average permanent resident population.

Statewide Projections

Alaska's statewide population is projected to most likely increase over the projection period, from 670,053 in 2006 to 838,676 people in 2030. As Alaska's population ages in the coming years, annual growth is expected to slow. Alaska's population aged 65+ is expected to grow at the highest rate over the projection period, followed by the population aged 0-17, and then the population aged 18-64. There is a great deal of uncertainty regarding what the actual levels of growth over the period will be, and statistical confidence intervals were estimated to express that uncertainty.

For the statewide projections, the population was divided into, and stepped forward in, single year increments. The process was repeated 2,000 times with random combinations of potential fertility and migration paths, and a fixed mortality path. This process provided a probability distribution for Alaska's future population, by sex and single years of age.

Alaska Native Projections

Alaska's Native population is expected to continue to grow over the projection period, from 118,884 people in 2006 to 162,820 in 2030. Similarly to the state as a whole, as the population ages, growth among Native Alaskans is expected to slow over time.

To create the Native and non-Native projections, the Native population was divided into, and stepped forward in five-year increments. This yielded population projections by sex and five-year age groups. Single paths, based on recent time series data and knowledge of the specified populations, were applied for each component of change.

Projections for Smaller Areas

Alaska's individual regions, boroughs and census areas are projected to grow at very different rates. The highest population growth is expected to occur in the Anchorage/Mat-Su Region, and the greatest (and only) population loss is expected to occur in the Southeast Region.

To create the borough and census area projections, the population of each area was stepped forward in five-year increments, using the cohort component method. This provided population projections by five-year age groups and sex. As with the Alaska Native projections, single paths, based on recent time series data and knowledge of the specified populations, were applied for each component.

Each of the borough and census area populations was projected independently, and the sum of these at each projection step matched closely to the median, or middle, statewide projections of that step. Any discrepancies between the median statewide projections and the sum of these smaller area projections were eliminated with a statistical fitting technique (described in Appendix A).

Outline

The report begins with a description of the components of population change for the statewide projections, then the results of the projections are described. Next, the components of population change that were applied to the Native Alaskan projections, and the results of the population projections for Native and non-Native Alaskans, are presented. Finally, the components of population change that were used in the borough and census area projections, and the results of the projections at the borough and census area level, are described.

Section 1

Alaska State Population Projections

Introduction

As of July 1, 2006, the State of Alaska was estimated to have a total population of 670,053. How Alaska reached a population of this level, and how this level will change in the future, is equal to the sum of four distinct processes, or "components" of change: fertility, mortality, in-migration and out-migration. Historical data regarding the level, trend and variability of each component of change was employed in these projections.

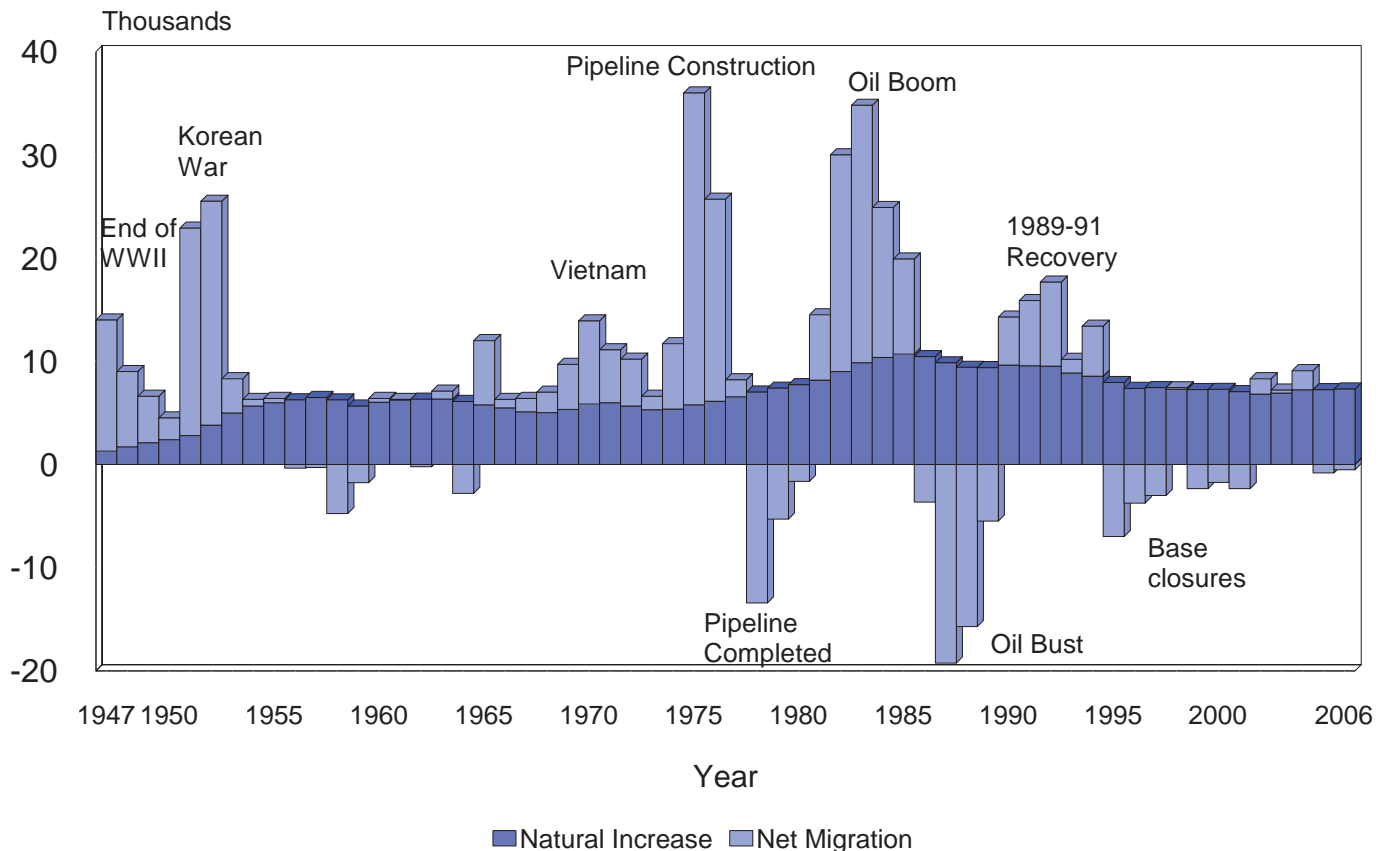

This section begins with a brief description of Alaska's recent population background. Alaska's mortality, fertility and migration levels, and their impact on the projections for Alaska's population, are then described. Finally, the results and interpretation of the statewide projections are presented.

Background

Since statehood in 1959, when Alaska's population level stood at roughly 224,000, there has been great variation in the rate of the state's growth. As shown in Figure 1.1, both "natural increase" (the difference between births and deaths) and "net migration" (the difference between in-migration and out-migration) have played important roles. The impact of natural increase has been steady and powerful. Numbers of births and deaths have not changed much from year to year, yielding a smooth, and to date positive-sided, path in the impact of natural increase on Alaska's population size.

In- and out-migration have been far more uncertain components of population change for Alaska. The rates and numbers of persons moving into and out of the state have varied greatly from year to year. In certain years, net-out-migration has been strong enough to even reverse the trend of annual growth.

But as Alaska develops, it is expected that both in- and out-migration levels, and consequently net-migration levels, will experience less dramatic annual shifts.

The discovery of oil in Prudhoe Bay in 1968, and the subsequent construction of the Trans-Alaska Oil Pipeline in the 1970's, had a massive impact on Alaska's population. The impact was seen both in the immediate term and, less directly, in the two decades that followed. Tens of thousands of workers and their dependents poured into the state for the construction of the pipeline, and many left the state at its completion. In the years that followed, Alaska would experience a huge in-flow of migrants with new oil revenues and increased oil prices, and also a large out-flow of migrants when oil prices dramatically fell in 1985.

The conditions of these projections do not include any likely events on the scale of the Trans-Alaska Pipeline. It is believed to be very unlikely that Alaska will experience such a powerful occurrence in the next 25 years. At the same time, it should be recognized that events of great magnitude do happen. The impact of the Trans-Alaska Pipeline helps to demonstrate that what is judged here to be unlikely, should not at all be judged as impossible.

Cohort Component Method

To create this set of population projections, a "cohort component" technique was used. Under this approach, the population of each sex is separated into specified age groups and aged forward in time, with projected in-migrants added, and projected out-migrants and deaths subtracted. Newborns are projected by applying projected rates of fertility to the female population at each projection step, then adding projected in-migrants, and subtracting projected out-migrants and deaths.

Two of the distinct benefits of this approach are its careful disaggregation of the components of population change (births, deaths and migration), and its production of population projections by age and sex.

To estimate the impact of mortality and fertility on population change, distinct rates of mortality and fertility are applied to each age-sex group as they are aged forward in time. To estimate the impact of migration, the number of persons resulting from annual rates of in- and out-migration for the total population are applied to age-by-sex profiles. The calculated number of in-migrants is added to the respective age-sex group, and the number of out-migrants is subtracted from the respective age-sex group.¹

Quantifying Uncertainty

With these population projections, as with all projections, uncertainty is a major factor. Traditionally,

demographers have summarized their uncertainty about future population levels by presenting high and low "variants," along with a most likely "middle" projection. This approach has been strongly criticized for not providing any statement on the likelihood of the high and low projections occurring. In recent years, demographers have developed techniques to create conditional probability distributions of future population, which better describe their level of uncertainty about the future.

The most common technique for creating such a "probabilistic" population projection is through the simulation of thousands of combinations of potential future paths for fertility, mortality and migration (the components of population change). Potential paths for these components are most often found through the use of historical data and expert judgment summarizing the level, trend and variance of each component. Many random combinations of potential paths are generated and implemented in a cohort component model, yielding a probability distribution for future populations.²

For the statewide population projections, such a simulation technique was used, where 2,000 potential paths for both fertility and migration were applied, with a fixed path for mortality. Uncertainty regarding future population is reported through 90% confidence intervals. Clearly, the level of certainty that is reported is subject to the historical data and statistical time series models used, and to the judgments that were made regarding uncertainty.

A single, most likely path of change is used to project rates of mortality. Mortality is the most predictable component of change, and though uncertainty regarding the future level of mortality is important for longer-term projections, and for projections of populations with large proportions of elderly persons, fertility and migration continue to dominate uncertainty about the future population of Alaska.

While probabilistic methodologies for population projection have been applied by non-governmental institutions for several nations and sub-national entities, to date they have rarely been used by government organizations in the U.S. It is hoped that data users find the approach useful.

¹ Further description of the "cohort component" method is provided in Preston, Heuveline and Guillot (2001).

² Further description of the techniques used for probabilistic population projection is provided in Appendix A. Some general descriptions of probabilistic population projection methods are provided in Lee, R. (1999), Miller, T. (2002), and Lutz, W., Sanderson, W., Scherbov, S. (1999).

Mortality

The strength of mortality may be summarized by the “life expectancy at birth.” The life expectancy at birth (or period life expectancy at birth) for a given year is equal to the average number of years that a person would live if he or she lived an entire life according to the respective year’s age-specific mortality rates. While life expectancy varies greatly from group to group within Alaska, Alaska’s total state life expectancy has been fairly close to that of the United States.

As shown in Table 1.2, life expectancy in Alaska and the U.S. has been somewhat stable over recent time, with steady improvement over recent decades. Given the stable nature of mortality rates in Alaska, a single path for change, based on the U.S. Social Security Administration’s projected future change in U.S. mortality, was applied.

Table 1.2
Life Expectancy at Birth:
Alaska and the United States, 1970 - 2030

Alaska Total Population	Male	Female
1970	66.1	74.0
1980	68.8	76.5
1990	71.6	78.7
2000	74.9	79.7
2010*	75.8	80.3
2020*	77.3	81.3
2030*	78.3	82.2
Alaska Native Population	Male	Female
1970	NA	NA
1980	61.3	71.3
1990	64.0	74.2
2000**	67.2	73.7

2020*	76.5	80.8
2030*	77.5	81.7

* Projected

** With the 2000 U.S. Census, the approach to defining race changed; this change may impact the life expectancy by race.

Sources: U.S. Social Security Administration, National Center for Health Statistics, and Alaska Department of Labor and Workforce Development, Research and Analysis Section, Demographics Unit

Allowing only one path for mortality may yield a somewhat conservative estimate of uncertainty regarding the size of Alaska’s future older population, but as the variation in mortality is quite limited relative to migration in Alaska, this approach should not have a major impact. That is, the greatest factor for the future size of Alaska’s older population is very likely to be migration, and not mortality.

As indicated in Table 1.2, the U.S. Social Security Administration projects that between 2000 and 2030, life expectancy will increase by 3.5 years for American men, and 2.3 years for American women. Following fitted parameters based on this change, life expectancy in Alaska is projected to increase by 3.4 years for Alaskan men, and 2.5 years for Alaskan women between the years 2000 and 2030.¹

Fertility

The level of fertility may be summarized by the “Total Fertility Rate” (TFR). The TFR for a specified year is equal to the average number of children that a woman would bear if she experienced that year’s age-specific fertility rates throughout her lifetime. A TFR of roughly 2.1 (2.1 children per woman) would be necessary for natural increase to break even. Alaska’s actual TFR ranks among the highest in the U.S., allowing for robust and steady growth attributable to natural increase.

As with life expectancy, the Total Fertility Rate varies greatly across the state, with estimates for specific area TFR’s ranging from as high as 4.73 in the Wade Hampton Census Area, to as low as 1.74 in Haines Borough. Based on a general trend in movement from rural to urban Alaska (where fertility is generally lower) as well as on national and global trends in fertility, Alaska’s TFR is projected to most likely converge to the expected value of 2.3. Using a statistical model with recent time series data, an estimate of the level of uncertainty around this value was made.²

Figure 1.2 helps to describe the expectation and uncertainty regarding Alaska’s future fertility level. There is an estimated 90% probability that the TFR will fall between the “High” and “Low” trendlines in a given year. There is an estimated 10% chance that the TFR will fall beyond either of the bounds in a given year, so that over a twenty-five year period, it may be understood as likely that the TFR will at some points fall outside of the given bounds.

Migration

Migration is the most uncertain component of population change for Alaska.

¹The method for fitting the mortality parameters is provided in Appendix A.

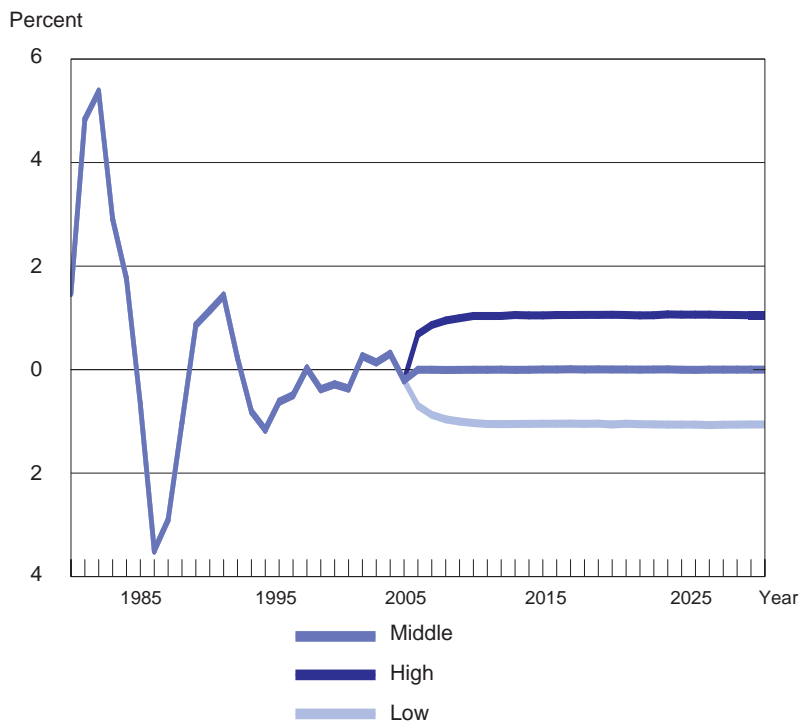

²The fertility model is provided in Appendix A.

 Source: Alaska Department of Labor and Workforce Development, Research and Analysis Section, Demographics Unit

As discussed earlier, the level of migration to and from Alaska has been greatly influenced at certain times by very distinct historical events, which have caused massive fluctuations in migration. Over the past two decades though, Alaska has experienced a relatively stable level of net migration, and these projections reflect this more recent stability.

To project migration for Alaska, two values were used: the annual ratio of in-migrants (the number of in-migrants divided by the mid-year in-state population), and the annual rate of out-migration (the number of out-migrants divided by the mid-year in-state population). The difference between the in- and out-migration values may be characterized as a net migration ratio, which is equal to the total number of in-migrants minus the total number of out-migrants, divided by the mid-year population. Using a statistical model with recent time series data, an estimated level of uncertainty around this value was determined.¹

Figure 1.3, shows the projected middle value of roughly zero for the net-migration ratio, with a 90% probability that it will fall within approximately plus or minus 1% of Alaska's population in any given year. Just as for the TFR, this means that for any given year, there is a one in ten chance that net-migration will fall beyond the high and low bounds.

After observing recent time series, major events (such as those that caused the erratic migration flows of the 1970's and early 1980's) were judged to be quite unlikely over the projection period. The effects of the construction of a natural gas pipeline in Alaska are not expected to be on the scale of the Trans-Alaska Oil Pipeline. It should be reiterated though, that even very unlikely events may occur over the next 25 years. Revisions will be made as new information becomes available.

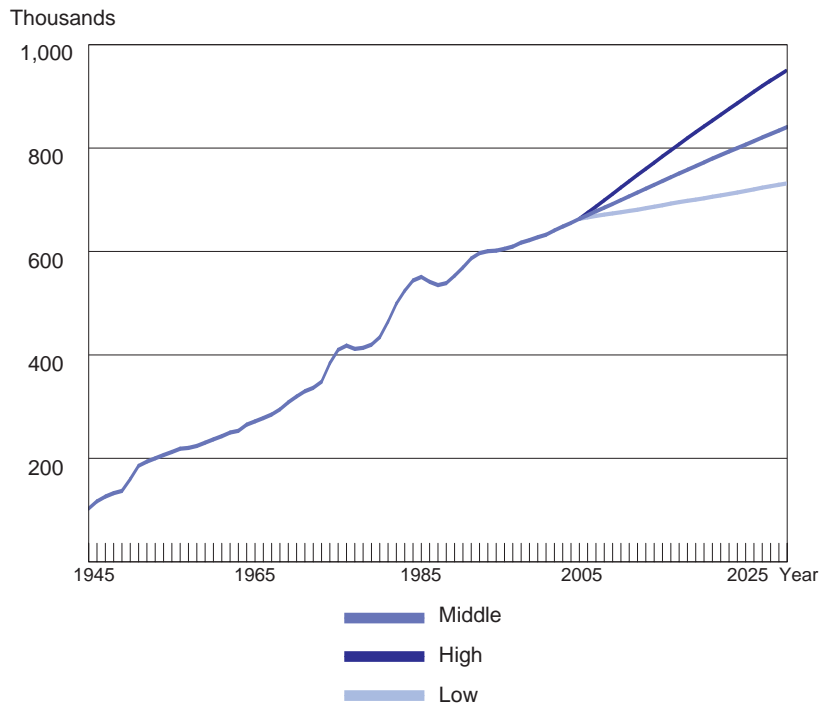

Components of Change

Table 1.3 displays estimates of potential future levels of births, deaths and net-migration. Looking first at future births, a likely increase in the number of births is projected to occur over the projection period, with greater uncertainty as time goes on.

The middle, or median, values for the given years indicate an estimated 50% probability that births will fall above or below the given value for the respective year. There is an estimated 90% probability that the actual values will fall within the high and low bounds for each respective year.

¹The migration models are provided in Appendix A.

Figure 1.4
Alaska Population 1945 - 2030*

* "Middle" is the median of the distribution, "High" and "Low" are the 90% confidence bounds.
Source: Alaska Department of Labor and Workforce Development, Research and Analysis Section, Demographics Unit

The generally rising number of births follows the trend of growth caused by a TFR above 2.1. Uncertainty in the number of future births over time is strongly influenced by uncertainty regarding the future of migration.

The number of deaths in Alaska is expected to increase greatly over the projection period. With the aging of the so-called "Baby Boom" generation (individuals born in the high fertility period of 1946-1964), Alaska, like all states, will gain a much larger elderly population. Uncertainty regarding the actual number of future deaths in Alaska is dominated by uncertainty with regard to future migration.

Migration, as demonstrated in Table 1.3, clearly yields the greatest amount of uncertainty. While the median value is close to zero throughout the projection period, there is great variation, with a 90% confidence interval as broad as nearly 17,000 people in 2030.

Alaska's Population Growth

Table 1.4 displays the projections for the levels of population growth in Alaska from 2006 to 2030, and the outcomes of this growth in the projected state population.

Table 1.3
Projected Annual Components Of Population Change For Alaska, 2006 - 2030*

July 1 to June 30 Year	Births			Deaths			Net Migration		
	Low	Middle	High	Low	Middle	High	Low	Middle	High

* "Middle" is the median of the distribution, "High" and "Low" are the 90% confidence bounds.
Source: Alaska Department of Labor and Workforce Development, Research and Analysis Section, Demographics Unit

With the expected increase in deaths relative to births, it is likely that the rate of growth will decline to some degree over the projection period. Still, putting migration aside, the most probable levels of fertility and mortality would yield continued growth.

By 2010, the most likely scenario has a population of 698,573, with 771,465 people in 2020, and by 2030, 838,676 people are projected to reside in Alaska. With time, uncertainty regarding Alaska's overall population size increases greatly. The projected population probability distributions follow a roughly "normal" (bell shaped) distribution. Figure 1.4 displays the projected path for Alaska's total population size, with an estimated 90% confidence interval.

Alaska's Future Population by Age and Sex

In Table 1.5, projections for population change in Alaska are broken down by age and sex. Two general qualities are apparent: (1) as the "Baby Boom" generation ages, Alaska's older-aged population will almost certainly grow greatly over the next 25 years, and (2) greatest uncertainty lies with regard to the population that is yet to be born—this group is dually impacted by the uncertain futures of both fertility and migration in Alaska. The median age of Alaska's population is projected to

increase at a steady pace from 33.5 to 34.6 between 2006 and 2030. The ratio of males per 100 females is expected to decline at a steady pace from 105.2 in 2006 to 102.4 in 2030.

Figures 1.5 through 1.10 show Alaska's projected "population pyramids" with associated 90% confidence bounds for the years 2007, 2010, 2015, 2020, 2025 and 2030.

Specific Age Groups

Figures 1.11 through 1.17 provide the projected population levels for specified age groups. Alaska's population aged 0-4 will most likely increase by 21%, from 53,456 to 64,425 people, between 2006 and 2030. As shown in Figure 1.11, there is relatively high uncertainty regarding this figure. High uncertainty for younger age groups is caused by the many possible future levels of both fertility and migration.

The population aged 5-13 represents children of elementary and middle school age. The most likely scenario for this group projects 25% growth, from 95,048 to 118,624 people between 2006 and 2030 (see Figures 1.12 and 1.13). While this group has decreased in size in recent years, this trend is not expected to continue.

Table 1.4
Population Growth Projections for Alaska, 2006 - 2030*

July 1 to June 30 Year	End of Period Population			Population Change			Average Annual Percent Rate of Change		
	Low	Middle	High	Low	Middle	High	Low	Middle	High

* "Middle" is the median of the distribution, "High" and "Low" are the 90% confidence bounds. The level of variance in the total population projections is slightly over-estimated (e.g. by approx. 10,000 persons for total population in 2030) to provide continuous, age-specific "variants." Further explanation is found in Appendix A. Source: Alaska Department of Labor and Workforce Development, Research and Analysis Section, Demographics Unit

The recent change in size has largely been the effect of the aging of the “echo boom” cohort, comprised of the children of the baby boomers. As this group moved into high school and college years, the population aged 5-13 experienced a temporary decrease in numbers.

The population aged 14-17 is comprised primarily of high school students. As shown in Figure 1.14, the population of these ages will most likely increase by 11%, from 46,243 people in 2006, to 51,320 in 2030. The size of this population in Alaska is currently at a historical high point, as the peak of the echo boom cohort is now of high school age. It is expected that the size of this age group will temporarily decrease in the coming years, and then enter a period of growth.

Alaska’s population aged 18-24 is largely made up of recent high school graduates and college students. The most likely scenario for this group projects 16% growth, from 66,231 to 77,022 people over the projection period (see Figure 1.15). As the echo boom moves through this age group, there will likely be a temporary increase, followed by a temporary decrease in the size of this population.

Alaska’s population aged 18-64 roughly represents the working-age population. Alaska’s working-age population is currently 429,817 people, and is expected to grow by 9% over the projection period, to 469,916 in 2030. As the baby boomers move into retirement years, the echo boomers will be moving into the working-ages, yielding almost no change in the working-age population for much of the period (see Figure 1.16). In the later years of the projection period it is expected that growth in this age group will pick up again.

The population aged 65+ is largely comprised of retirees. Very strong growth for this age group is expected throughout the projection period. Currently, Alaska’s population aged 65+ is comprised of 45,489 people. The most likely scenario for this group projects 134,391 people aged 65+ in 2030. As shown in Figure 1.17, this represents a more than tripling in size over the 25-year period. Growth in this age group is fully attributable to the large cohort of baby boomers, who are currently beginning to retire.

The massive change in the size of the population age 65+ will no doubt play a major role in shaping Alaska’s future. Because Alaska has historically had a relatively small old-age population, the state will need to prepare for the change. The growth of the senior population will surely present new challenges to find funding and build infrastructure in support of more retirees.

Dependency

Dependency ratios show how large a burden of support is placed on the working age population to care for the

young and old, both largely non-working populations. In 2006, every 100 Alaskans of working age supported 45.3 people under age 18, and 10.6 persons over age 65. Both of these figures are expected to rise over the next 25 years. The youth dependency ratio will most likely first decrease to 43.9 in 2010, then rise to 47.6 in 2020, and 49.9 in 2030. The aged dependency ratio is expected to increase to 12.1 by 2010, then 21.2 by 2020, and 27.9 by 2030. Though there is some uncertainty in these specific figures as well, the old age dependency ratio will almost certainly increase dramatically over the next 25 years.

Section 2

Alaska Native and non-Native Population Projections

Introduction

This section presents population projections for Alaska's Native (based on the Alaska "bridged" race estimates) and non-Native populations, by age and sex, from 2010 through 2030. While all Native Americans residing in Alaska are included in the Native projections, the group is dominated by Alaska Natives, and will be referred to here as Alaska Natives. The Alaska Native population currently represents approximately 18% of the state's total population. With high fertility and relatively low rates of migration, Alaska Natives represent a source of stable population growth for the state. Given the relatively consistent rates of change for the Native population over time, and inconsistent definitions of "Native" in historical data, it was decided to not create probability distributions or high and low variants for the Alaska Native projections. Users should be aware, though, that these projections are based on recent rates, which will vary to some degree over time.¹

Methodology

The Native population was divided into groups according to age and sex, and projected forward in five-year steps from the 2005 Alaska "bridged race" population estimates, using the "cohort component" method. Projected births and in-migrants were added, and projected deaths and out-migrants were subtracted at each step, for each age-by-sex group. The projections for Alaska's non-Native population are simply the "Middle" (median) projection for the total statewide population, minus projected Alaska Natives. Recent statewide Alaska Native fertility and mortality data by age were used to inform the projections of natural increase. In- and out-migration data from the Alaska Permanent Fund and the 2000 Census was used in projecting migration by age.¹

Mortality

Rates of mortality for Native Alaskans are among the highest in the United States. To project future life expectancy for Native Alaskans, model parameters, based on the U.S. Social Security Administration's projections for change in U.S. life expectancy over the projection period, were used.

As shown in Table 1.2 (see page 10), between 2000 and 2030, the life expectancy at birth for Native Alaskans is projected to increase from 67.2 to 73.3 for males and from 73.7 to 77.5 for females. Due to the overall aging of the population, the annual crude death rate (number of deaths per 1,000 people) for Native Alaskans is expected to increase from roughly 6.5 in 2005 (based on recent Alaska vital statistics and population estimates data) to 7.3 in 2030.

Fertility

Fertility rates for Alaska Natives are also among the highest in the nation. In 2005, the total fertility rate, or average number of children per woman, stood at 3.2 for Alaska Natives. The total fertility rate is projected to decline to roughly 3.0 by 2030.

The expected decline in fertility for Alaska Natives is in part associated with Alaska's trend of rural to urban migration. As more Alaska Natives move to more urbanized environments, it is expected that their rates of fertility will decline, becoming more similar to those found in their new locality. With the slightly lowered fertility and aging of the Native population, the annual crude birth rate (number of births per 1,000 people) for Native Alaskans is expected to decrease slightly during the projection period, from 23.1 in 2005 (based on recent Alaska vital statistics and population estimates data) to approximately 21.1 in 2030.

Migration

Rates of migration into and out of Alaska by Alaska Natives are relatively low compared to the state population as a whole. Using data from the 2000 U.S. Census and the Alaska Permanent Fund, it is estimated that Alaska Natives leave the state at a rate of slightly more than one percent (of the in-state population) each year, and enter the state at just under one percent per year, yielding a very slight annual loss through migration. The projections continue these levels of migration through to 2030.

Overall Population Change

Alaska Natives are projected to experience stable growth over the projection period, from 118,884 in 2006 to 162,820 in 2030. Further, Alaska Natives are projected to grow as a share of the state's population, from 17.7 percent of the total state population in 2006, to 19.4 percent in 2030. Though both annual births and annual deaths are projected to increase strongly, numbers of births are consistently projected to be much higher than numbers of deaths.

Aging

Aging will play a major role in population change for Alaska Natives over the projection period. The median age for the population is projected to rise from 25.2 to 28.7 between 2006 and 2030. The proportion of Alaska Natives aged 65+ out of the total Alaska Native population is expected to increase from 6% in 2006 to nearly 12% in 2030.

¹Further description of the Native "bridged" estimates, the projection methodology, and the methods for estimating age-by-sex specific mortality, fertility and migration is provided in Appendix A.

Section 3

Alaska Region, Borough and Census Area Population Projections

Introduction

This section presents population projections for Alaska's economic regions, boroughs and census areas, by age and sex. With population projections of smaller areas, there is a much higher level of uncertainty. Inter-borough migration, highly specific policy and economic factors, and unique historical events all play an important role. Single projections, based on recent trends, are presented at the borough and census area level. Users of this data should be aware that there is a high degree of uncertainty regarding the future of these area populations. Countless factors could sway many of these populations quite dramatically.

The projected populations for each region, borough and census area are presented by age and sex, in five-year increments covering the years 2010 through 2030. High and low variants for the total populations of the areas are presented in Table 3.1, but they are not associated with any specified statistical confidence level.

Methodology

For each borough and census area projection, the population was divided into age-by-sex groups, which were projected forward in time from the year 2005 population estimates using the "cohort component" method. Projected births and in-migrants were added, and projected deaths and out-migrants were subtracted at each step, for each age-by-sex group. The projections for Alaska's economic regions are simply the sums of the boroughs and census areas that they cover.¹

Each of the borough and census area populations was projected independently, with recent age-specific fertility rates used to project births, recent and projected age-by-sex specific mortality rates used to project deaths, and recent annual migration data (adjusted for five-year intervals) and age profiles used to project migration. For some of the smaller boroughs and census areas, data is quite limited, and it was necessary in certain cases to pool data from similar areas. Furthermore, for the Aleutians East Borough and Aleutians West Census Area, the group quarters (population not living in households) populations were held constant in age and size throughout the projection period.²

The sum of the individual projections at each projection step matched very closely to the middle, or median, statewide projections of that step. Any discrepancies between the middle statewide projections and the sum of the borough projections were eliminated with a statistical fitting procedure.³

Births

In 2005, the crude birth rate, or number of births per 1,000 persons, was 15.4 in Alaska. With the overall aging of Alaska's population, this figure will most likely decline over time, with roughly 14.9 as the middle projected value for the year 2030. Among the particular boroughs and census areas, the highest crude birth rates in 2005 were found in Wade Hampton Census Area with 28.2, Bethel Census Area (24.5), North Slope Borough (26.0), and Nome Census Area (23.5). The lowest birth rates for the boroughs and census areas were found along the Aleutian Chain and in Southeast Alaska. In the Aleutians East Borough and Aleutians West Census Area, where much of the population lives in group quarters for fishing and fish processing employment, the birth rates were 7.9 and 6.2, respectively. In the Southeast Region, Haines Borough had a crude birth rate of 8.5, Wrangell-Petersburg Census Area 10.2, and Skagway-Hoonah-Angoon Census Area 10.5.

It is expected that there will not be much change in the rank-order of crude birth rates for Alaska's boroughs and census areas over the projection period. While there will certainly be change in these values as the population composition changes over time, places with relatively high birth rates will likely remain comparatively high, and those with low birth rates will likely remain low.

Deaths

In 2005, the crude death rate, or number of deaths per 1,000 persons, was 4.4 in Alaska. The greatest contributor to this figure is the ratio of elderly persons to the overall population. As Alaska's population gains a higher proportion of elderly persons, this figure will increase greatly over time. Alaska boroughs and census areas with the highest crude death rates in 2005 included Haines Borough with 10.3, Lake and Peninsula Borough (8.8), and Yakutat Borough (7.8). Those with the lowest crude death rates included Aleutians East Borough (2.3), Aleutians West Census Area (2.6), and Fairbanks North Star Borough (3.6).

With the aging of Alaska's population over the projection period, there will likely be increases in the crude rates of death for all of the boroughs and census areas.

¹Further description of the cohort component method is provided in Preston, Heuveline and Guillot (2001).

²Further description of the methods for estimating age specific mortality, fertility and migration rates are provided in Appendix A.

³A description of iterative proportional fitting is provided in Smith, Tayman and Swanson (2001).

Migration

As with statewide migration, migration into and out of Alaska's boroughs and census areas represents a highly unstable component of population change. To project migration for Alaska's boroughs and census areas, two values were used: the annual ratio of in-migrants (the number of in-migrants divided by the total population), and the annual rate of out-migration (the number of out-migrants divided by the total population). Both of these values were estimated annually for each borough and census area from 1990 to 2005, and this data was used to project migration through 2030. The rates are shared out proportionally to age-by-sex profiles to estimate migrants for specific groups. The migration levels applied for the projection period broadly reflect those experienced over recent history.

Areas expected to experience the positive levels of net migration throughout the projection period include the Matanuska-Susitna Borough and Kenai Peninsula Borough. Each of the boroughs and census areas of the Southeast Region are expected to experience negative values for net-migration strong enough to limit any population growth. Rural boroughs and census areas with high fertility rates, such as the Wade Hampton and Nome census areas, and the North Slope and Northwest Arctic boroughs, are projected to experience strong negative values for net-migration, but continue to grow through natural increase.

Overall Results

The general trends for Alaska's economic regions includes some degree of growth over the period for all of Alaska's regions except Southeast. As shown in Figure 2.1, strongest growth is projected to be in the Anchorage/Mat-Su Region, with the Matanuska-Susitna Borough projected to nearly double in size over the projection period. While the continuation of recent population trends yields no growth for Southeast Alaska, it is of course quite possible that such trends will change in the future.

No change in the population rank-ordering of the regions is expected to occur over the period. Though somewhat strong net losses by migration for the Northern and Southwest Regions are projected, the high fertility rates found in these areas will likely allow continued growth.

The boroughs or census areas with the highest levels of projected average annual growth over the period include: Mat-Su Borough (2.34%), Wade Hampton Census Area (1.33%), and North Slope Borough (1.10%). The boroughs or census areas with the greatest levels of projected average annual population loss over the projection period include: Skagway-Hoonah-Angoon Census Area (-1.8%) and Haines Borough (-1.46%).

Appendix A

Technical Notes

Introduction

This technical appendix provides information on the methods used to develop the 2007-2030 Alaska Population Projections. Models used to estimate statewide mortality, fertility and migration rates are first presented. Application of the modeled data in a “cohort component” projection model is then described. Next, the methods for projecting borough and census area mortality, fertility and migration rates, and applying these to borough and census area population projections are described. Finally, the “bridged” race estimates, and the methods for projecting Alaska Native births, deaths, migration and population are presented. All computations were made using the R statistical package, SPSS and Microsoft Excel.

Statewide Mortality

The method to model mortality made use of the Brass relational logit model for mortality (Preston, Heuveline and Guillot, 2001). Linear interpolation was used to estimate annual U.S. life tables for 2000-2030, based on the 2000, 2010, 2020 and 2030 U.S. Social Security life tables (Bell and Miller, 2005). Brass coefficients were then calculated for each year, with the interpolated 2004 U.S. table as the Brass standard. The next step was to apply the calculated annual Brass coefficients to an Alaska 2003-2005 life table, which was created with the use of Alaska vital statistics data. Applying the Brass coefficients to an Alaska standard life table produced age-specific rates of mortality for 2004 through 2030, based on projected change in U.S. mortality.

Statewide Fertility

To project fertility, the sum of the age-specific fertility rates, known as the total fertility rate (TFR), was used as an index value. A mean constrained autoregressive model was created to generate various potential future TFR's. That is, the strength of autocorrelation (correlation between TFR's of any two consecutive years) was estimated, and the mean of the annually projected TFR's was constrained to converge to a pre-specified, fixed value over time. Maximum likelihood fitting was used on Alaska's 1975-2005 annual TFR's to estimate fixed autocorrelation and variance. The mean constraint was set to 2.3, which is believed to be the most likely TFR level as time goes on. The following is the model for annual fertility ($F[t]$ is equal to the total fertility rate in a given year):

Total Fertility Rate:
 $F[t] = F[t-1] * .8762 + .2847 + \text{error}$
Standard error: .0727

Two thousand modeled paths for the TFR were then applied

to a fixed age profile of fertility, which generated various age specific fertility rates for each year from 2005-2030. The age profile for fertility was created by calculating proportional age specific fertility rates from Alaska vital statistics for the years 2000-2005.

Statewide Migration

To project migration for Alaska, two values were used: the annual ratio of in-migrants (the number of in-migrants divided by the mid-year population), and the annual rate of out-migration (the number of out-migrants divided by the mid-year population) as indices. Autoregressive fitting was applied to the 1980-2005 time series of these values. Using maximum likelihood estimation, parameters were estimated for a fixed level of autocorrelation and variance. Because it is believed that the net-migration level over the projection period will follow the level of variance experienced in the 1990-2005 period, a proportional adjustment of the error terms was made, such that they yielded a level of variance in net-migration similar to that experienced between 1990 and 2005. The mean levels of both in- and out-migration were fixed to equal the most recent levels of 5.3%. The following are the models for annual in- and out-migration ($M[t]$ is equal to the migration level in a given year):

In-Migration Ratio:
 $M[t] = M[t-1] * .7683 + .0122 + \text{error}$
Standard error: .0039

Out-Migration Rate:
 $M[t] = M[t-1] * .8234 + .0093 + \text{error}$
Standard error: .0020

Two thousand modeled paths for the in- and out-migration levels were applied to fixed age-by-sex share profiles for in- and out-migration, which generated projected age-by-sex specific migration values for each year from 2005-2030. The age-by-sex profiles for migration provide calculated shares of the overall number of projected migrants for each age and sex group. Estimation of the age-by-sex migration profiles was carried out with use of the Alaska Permanent Fund, by subtracting births and deaths from annual non-matches (persons not present in consecutive annual Permanent Fund files).

Statewide Projection Model

After calculating two thousand sets of component paths for each age and sex, they were applied to a cohort component projection model (Preston, Heuveline and Guillot, 2001). More specifically, Leslie Matrices were used to project natural increase, with projected vectors of migrants added at each step.

This process generated a distribution of two thousand potential population paths from 2005-2030, and estimates the conditional probability distribution for Alaska's future population. The sum of the boundaries of the 90% confidence intervals for each age-by-sex are reported as the 90% confidence high and low variants. This slightly over-estimates (by up to roughly 10,000 persons in 2030) the true confidence interval calculated for just the total population, as the correlation of population change across the ages is in actuality less than 1, but it provides users with continuous high and low variants.

Borough and Census Area Mortality

Given the very small populations of Alaska boroughs and census areas, it was not feasible to create age-by-sex specific mortality rates at the sub-state level. But rather than applying the statewide levels of mortality to each borough and census area, it was decided to account for the distinct racial composition of each area, and to adjust the levels of mortality accordingly. Levels of mortality were linearly interpolated between statewide Alaska Native and non-Native life tables, based on the total proportion of Alaska Natives in each borough or census area. The next step was to apply the Brass projection coefficients that were calculated for statewide mortality to the interpolated life tables. Applying the Brass coefficients yielded age specific rates of mortality for 2005 through 2030, based on the U.S. Social Security Administration's projected change in U.S. mortality.

Borough and Census Area Fertility

For fertility by borough, the age-specific rates of fertility were calculated for the years 2000-2005, and applied as the age-specific fertility rates for the boroughs through the projection period. For very small boroughs and census areas, it was necessary to pool the fertility data with similar areas. Because the projected decline in Alaska's total fertility rate is expected to come from migration from rural to urban Alaska over the period, and not any necessary lowering of borough-specific fertility, it was not necessary to lower the borough and census area fertility rates over time.

Borough and Census Area Migration

To estimate migration by borough, the Alaska Permanent Fund micro-data and the U.S. Internal Revenue Service migration data for 1990-2005 were used. Migration data was constructed from the annual Permanent Fund data by subtracting births and deaths from annual non-matches (persons not present in consecutive annual Permanent Fund files). This data was then averaged with the U.S. Internal Revenue Service annual estimates of migration rates. The overall levels of migration were applied to age-by-sex-share profiles that were calculated from the Permanent Fund data.

Borough and Census Area Projection

To project the population of each borough and census area, the cohort component method was applied in

the same manner as the statewide projections, but in five-year steps, and with fixed levels for fertility and migration. After projecting each of the borough populations from 2005 to 2030, the results were compared with the "Middle" (median of distribution) variant statewide projections, and were found to match very closely. To measure the closeness of the statewide and sum-of-borough population projections by age and sex, the "mean absolute percent error" (Smith, Tayman and Swanson, 2001) was calculated across the ages and sexes, and found less than 10% average error among the age-by-sex groups for each projection step. The data was fitted completely with the use of "iterative proportional fitting" (Smith, Tayman and Swanson, 2001). The "High" and "Low" borough and census area variants are simply proportionally adjusted based on the statewide 90% confidence bounds, and do not reflect any specified level of statistical confidence.

Alaska Native "Bridged" Estimates

With the year 2000 Census, the U.S. Census Bureau began allowing persons to be classified under more than one race category. Because vital and educational statistics (among others) do not have a multi-race option, data by race is much less clear from 2000 forward. The "Equal Proportion Bridge Series" race data series presented by the Alaska Department of Labor, Research and Analysis Section, attempts to address this problem. Further description, and data from 1990-2006 are provided online (<http://almis.labor.state.ak.us/?PAGEID=67&SUBID=171>).

Alaska Native Population Projections

To project the Alaska Native population, estimates were first made of age-by-sex specific mortality from 2003-2005 Alaska vital statistics data. The U.S. Social Security Administration Brass coefficients were applied to create projected mortality data for Alaska Natives through 2030. Fertility was then estimated with the use of 2000-2005 vital statistics data, and the levels were adjusted proportionally to match the level of projected change in statewide fertility over the projection period. Migration was estimated for Alaska Natives using 2000 U.S. Census and Alaska Permanent Fund data, with age profiles determined by the 2000 U.S. Census. The estimated 2000-2005 migration levels are continued through the projection period. The cohort component method is applied just as for the borough and census areas, to create the population projections. The difference by age and sex between the Alaska Native projections and the "Middle" (median of distribution) statewide projections is attributed to the non-Native population.
