INTRODUCTION

This catalog lists routinely determined parameters of earthquakes occurring within and adjacent to the areas encompassed by the network of seismograph stations operated and/or recorded by the Geophysical Institute of the University of Alaska (UAGI). Our goal in generating this catalog is to provide a convenient reference source for the earthquake activity in the areas covered and to provide a quantitative set of information on the basis of which interested researchers, administrators, planners, and others can judge to what extent related data files residing on the Geophysical Institute's computer system, might be useful for their various needs. We therefore not only provide hypocentral parameters but also information about the quality of input data and accuracy of the derived parameters, so that potential users of both raw and derived data can obtain some idea as to which type of further data analysis these data would lend themselves. While, on account of the number of events, the present catalog is the result of routine processing, reasonable care has been taken to locate earthquakes accurately and to use as many useful data as possible. This is especially true for events of magnitude 3 and larger. Additional data, primarily from networks operated by other agencies, and more sophisticated methods of analysis might, however, in many cases lead to more accurate locations.

DATA

The data used in preparing this catalog are derived from two principal sources: from seismic stations operated by the Geophysical Institute and from seismic stations operated by other agencies but continuously recorded by us under various data sharing or data exchange agreements. Also, for events of about magnitude 3 or larger, arrival times for many stations of NOAA's Tsunami

Warning System are made available to us in the form of copies of their daily TELEX message of arrival times sent to the National Environmental Information Service in Boulder.

Figure 1 shows all stations of the University of Alaska network, and all stations operated by various other agencies (with the exception of the NOAA station Nikolski which locates just outside the map areal from which data have been used for the preparation of this catalog.

Geographic coordinates and other pertinent information about these stations are given in Table 1.

Signals from the various, usually remotely located, stations are transmitted by means of a combination of UAGI operated VHF radio links and leased commercial telephone circuits to one of the two recording centers of the University of Alaska network in Homer and Fairbanks. Remote stations are serviced and calibrated once a year, stations with year-round road access are serviced more often if necessary. In the case of malfunctioning, the difficulties of access associated with many stations can lead to lengthy data losses and, in turn, to lower detection thresholds and solution qualities for earthquakes located in the affected regions. In order to discern such conditions we provide a station use record in Figure 2. Stations with lengthy outages can be identified on this figure. It should be noted, however, that especially in the case of stations not operated by the University of Alaska non-use does not necessarily imply station outage but rather that no data were required for earthquake location purposes.

The data are recorded on 16 mm film on several Teledyne Geotech Uvelocorders, each of which has a maximum capacity of 20 channels. Satellite linked clocks provide timing marks which are superposed on the records. Figure 3 gives the typical response of the total system from transducer to recorder.

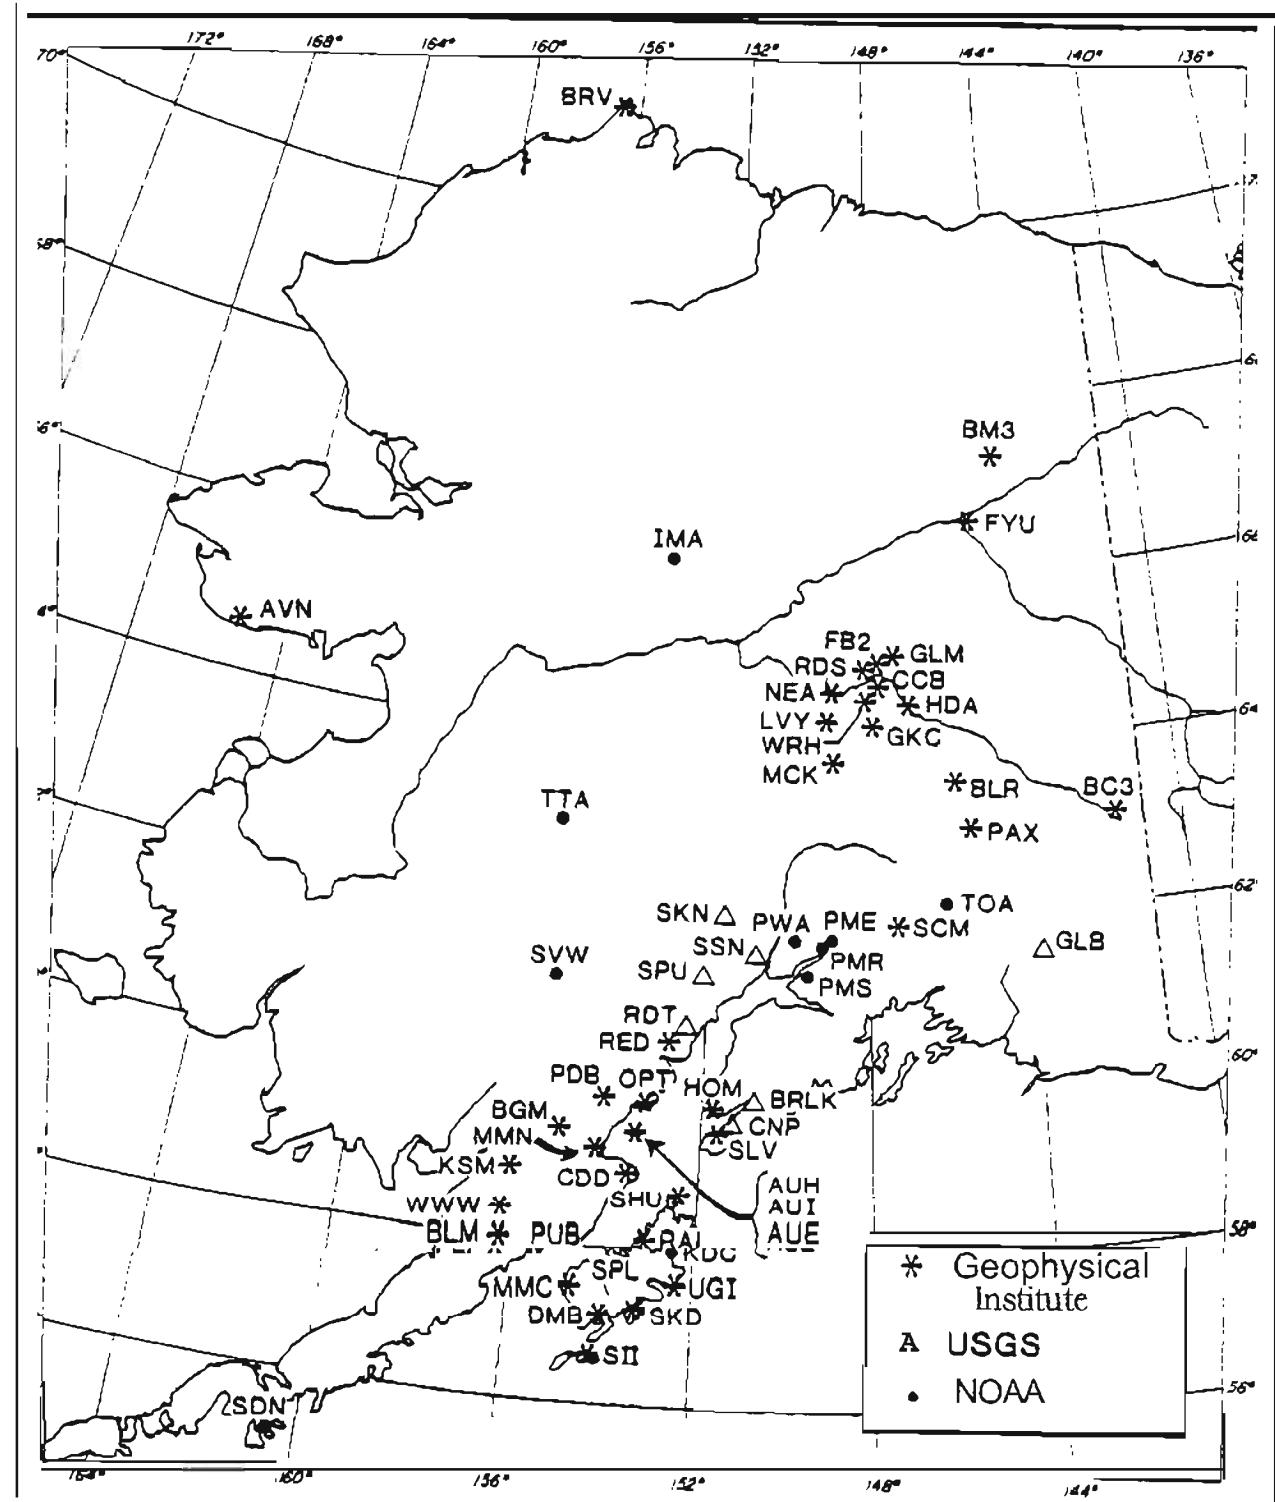

Figure 1: All seismograph stations operated by the University of Alaska and stations of other organizations from which data were used in preparing this bulletin. The stations BGM, PDB, and SLV were originally installed and operated by USGS and are presently maintained by the University of Alaska.

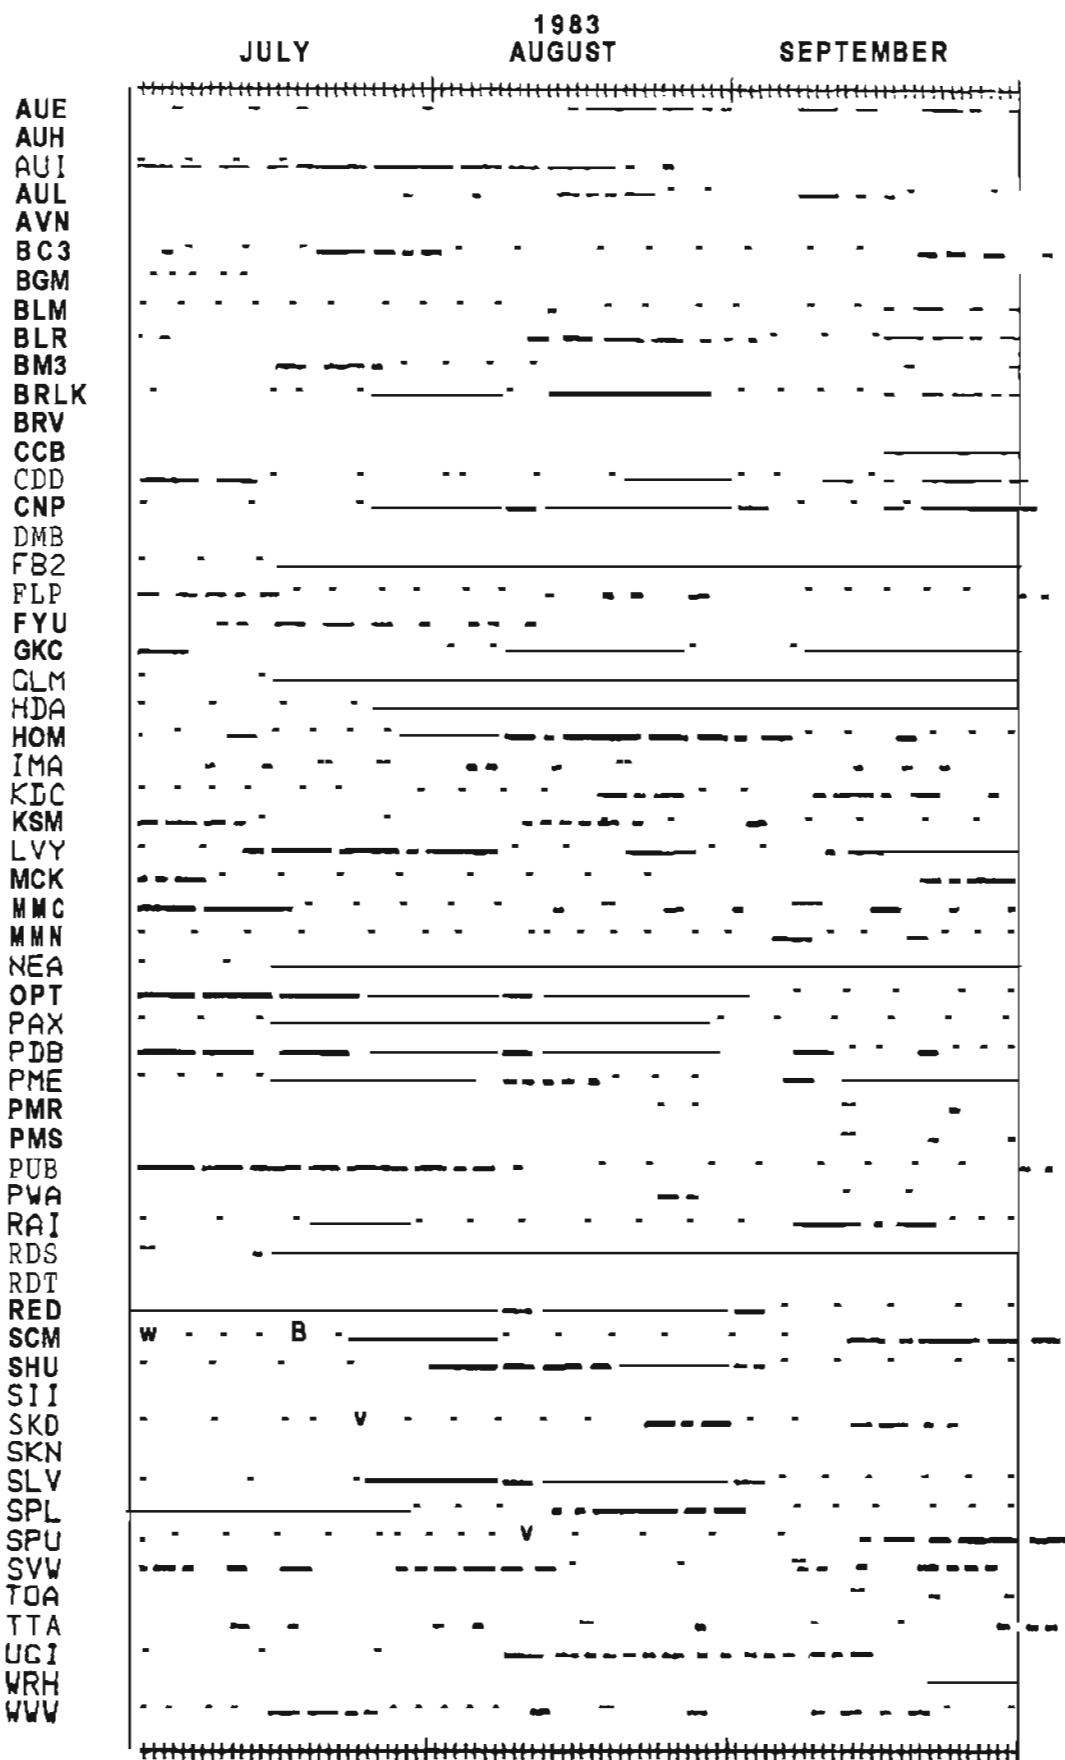

Figure 2: Station use record. A dash associated with a particular station on a particular date means that at least one arrival-time reading from that station was used on that date.

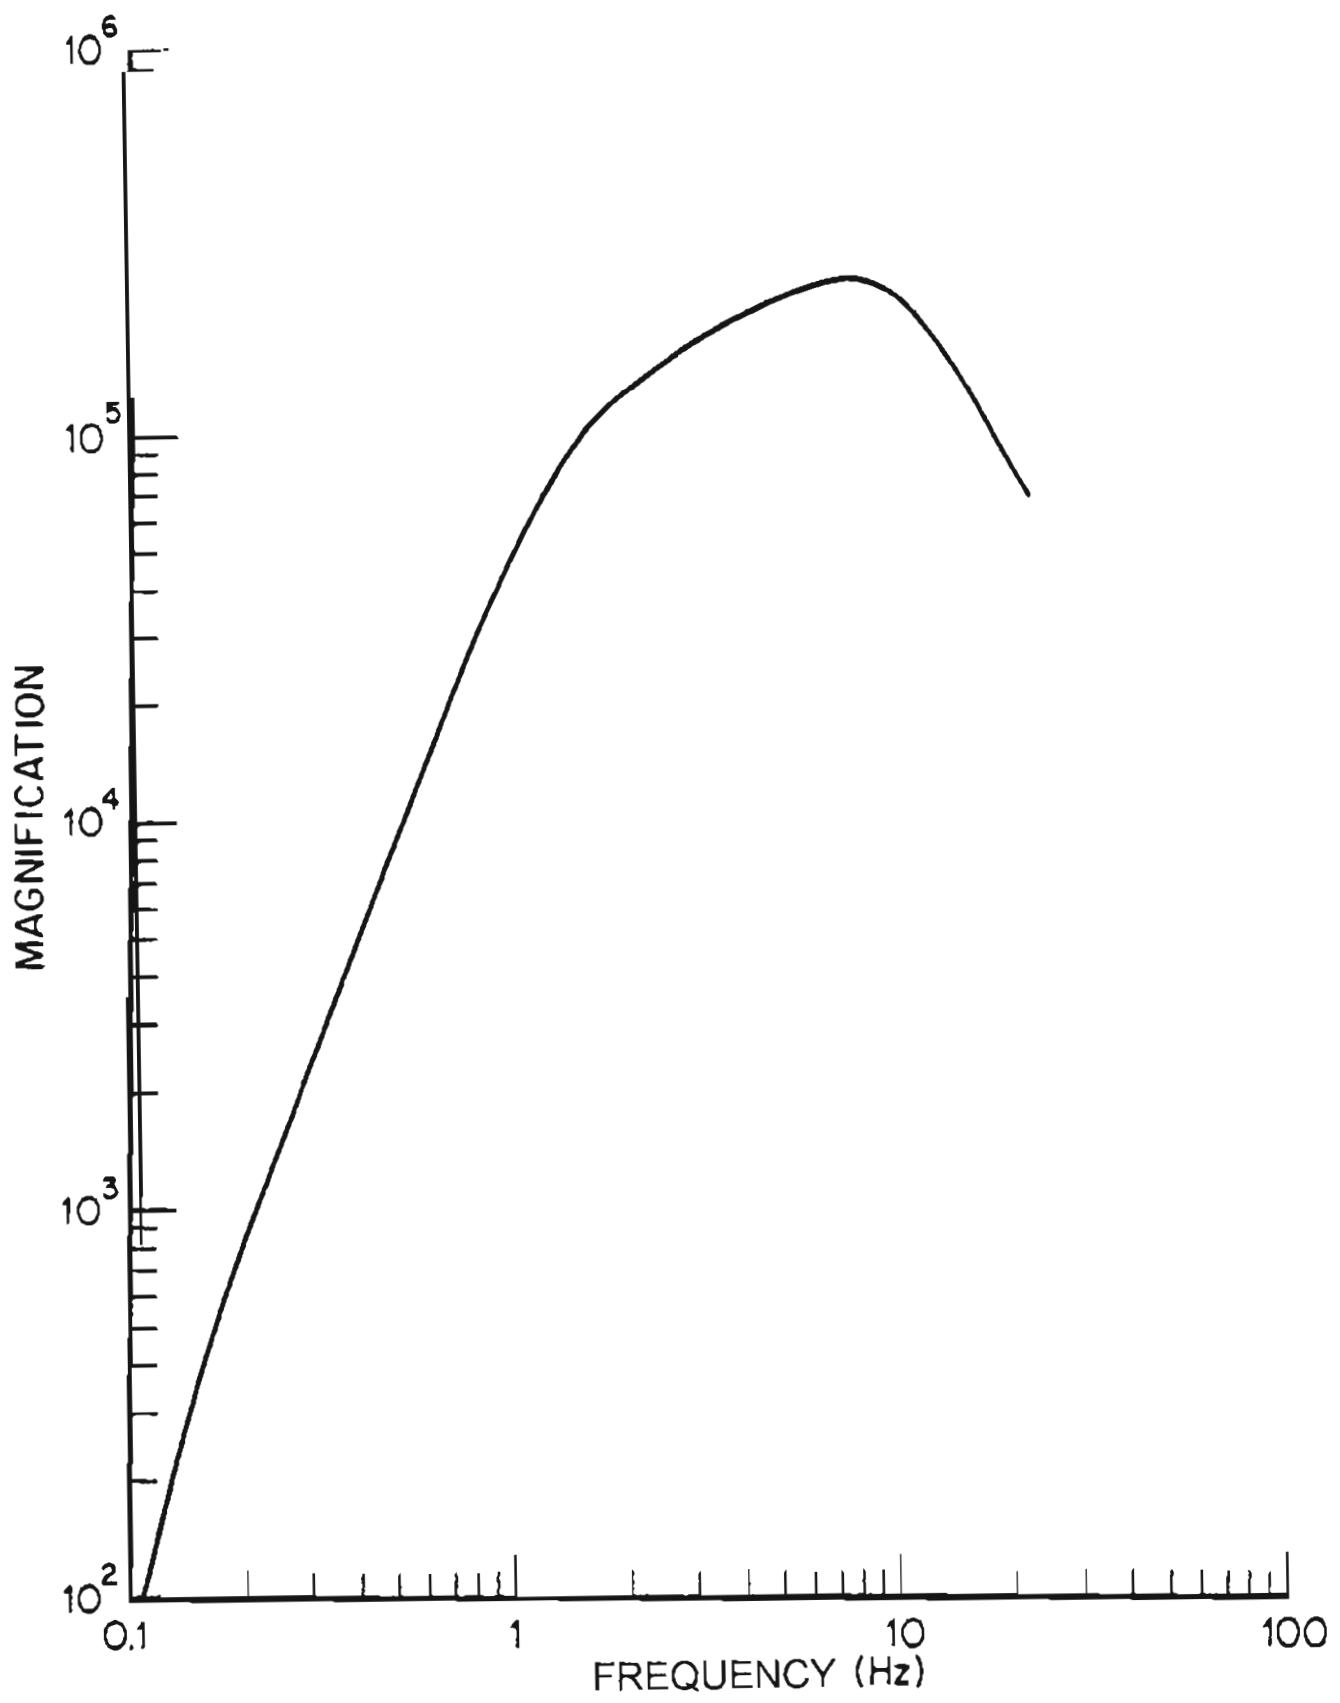

Figure 3: Typical system response curve for University of Alaska stations.

Table 1. Names and pertinent parameters of seismic stations used in preparing this catalog. For description of velocity models see text.

DATA PROCESSING

Arrival times are read on Geotech filmviewers which provide a resolution of up to 3 lines per millimeter. Thus, the most impulsive arrivals can be read to .05 sec.

Earthquake locations are based on P and S arrivals. As many S arrivals as possible are used to help constrain hypocentral depth. The large majority of the S readings are obtained from vertical components since only few three component systems are recorded. Owing to the nature of the multichannel film recordings in the case of a large event, traces overlap each other making the identification of S arrivals very difficult. The gradual transition to a digital tape recording system, presently underway, will greatly improve this situation.

After identification of events and determination of arrival times, phase data are processed by computer to obtain the earthquake parameters using the computer program HYPOELLIPE (Lahr, 1980). Each solution is checked for travel time residuals greater than or equal to 0.5 sec and for the spatial distribution of stations used. Events that produce large residuals are re-read and for shocks with poor station distribution readings are sought from additional stations, not recorded by the University of Alaska. Events recorded by only five stations or less receive little additional attention. Events of magnitude 3.5 and larger are processed very carefully, sometimes by changing various control parameters in the computer program.

VELOCITY MODELS

Since most computer algorithms for locating earthquakes are based upon some iterative scheme of minimizing the difference between calculated and observed travel times between hypocenter and the stations, a seismic velocity structure has to be provided.

The tectonic regime and geological setting vary greatly throughout the area covered by the University of Alaska network. Although our knowledge of the details of the seismic velocity structure is rather limited, considerable variation seems to exist. To take this variation into account each of the University of Alaska stations, depending on its location, is associated with one of three different velocity models. Regardless of the location of the hypocenter, that structure is used in calculating the travel time to that station. The models used are all one dimensional, varying only with depth, and lateral velocity variation (which is especially strong in the vicinity of the subduction zone) is not taken into account. For stations which are not part of the University of Alaska network we generally use models adopted by the operators of these stations. Column 6 of Table 1 indicates the particular velocity model with which each station is associated.

The University of Alaska presently uses the following models:

Model 1

Layer	Depth (km)	P Velocity (km/sec)
1	0-24	5.9
2	24-40	7.4
3	40-76	7.9
4	76-300	8.3
5	301-545	10.4
6	Below 545	12.6

This model is used primarily in central and northern Alaska. It was derived from travel-time studies to central Alaskan stations from teleseismic and regional earthquakes (Biswas and Bhattacharya, 1974).

Model 2

Layer	Depth (km)	P Velocity (km/sec)
1	0-2	2.75
2	2-4	5.3
3	4-10	5.6
4	10-15	6.2
5	15-20	6.9
6	20-25	7.4
7	25-33	7.7
8	33-47	7.9
9	47-65	8.1
10	below 65	8.3

This model is associated with stations located in the Cook Inlet-Kenai Peninsula area. It is based on the model of Matumoto and Page (1969) determined for the Kenai Peninsula from travel time studies of 1964 Alaska earthquake aftershocks. This model is used by USGS in this area for location purposes.

Model 3

Layer	Depth (km)	P Velocity (km/sec)
1	0-1.6	4.2
2	1.6-12	5.5
3	12-42	6.6
4	42-60	8.06
5	60-80	8.09
6	80-100	8.11
7	100-150	8.14
8	150-200	8.27
9	200-250	8.41
10	250-300	8.50
11	300-350	8.74
12	below 350	9.02

This model is used in connection with stations located on Kodiak Island and the Alaska Peninsula. This structure was obtained by Engdahl and Tarr (1970) from refraction experiments, in the central Aleutians.

For all models the S velocity is taken to be equal to the P velocity divided by the square root of three.

MAGNITUDE

Magnitudes are determined from the maximum amplitude of the body wave trace. The relationship derived by Richter (1954) for records of local California earthquakes from horizontal, standard Wood Anderson seismographs is used. Proper adjustments are made for differences in the response characteristics and magnification between the standard instrument and the system actually used. However, no corrections are made for any differences in attenuation properties between California and the various Alaskan regions or the fact that vertical rather than horizontal ground motion is measured.

For a given earthquake, its magnitude is usually calculated at several stations and then averaged.

In the case of large events, when the maximum trace amplitude saturates on most of our stations, we frequently list local magnitude as determined by NOAA's Palmer Observatory. When this is the case, it is indicated in the listings after the event. When available, we also list felt reports after the events and observations of the Modified Mercalli Intensity (Richter, 1958). The definitions of the various intensity levels are given in the Appendix.

DISCUSSION OF THE CATALOG

The Appendix lists hypocenter parameters, magnitude and quality parameters of earthquakes located during the third quarter of 1983. The listings are in two groups: one for events north of 61°N and one for events south of it.

Epicenters for the same time period are plotted in Figures 4 through 6. For the areas of Figures 4 and 5, the epicenters of events of $M_L > 3$ are shown in Figures 7 and 8 respectively. Figure 6 shows only events located outside the areas encompassed by Figures 4 and 5. These events are generally of poor quality and located either because our network appeared to be the only one

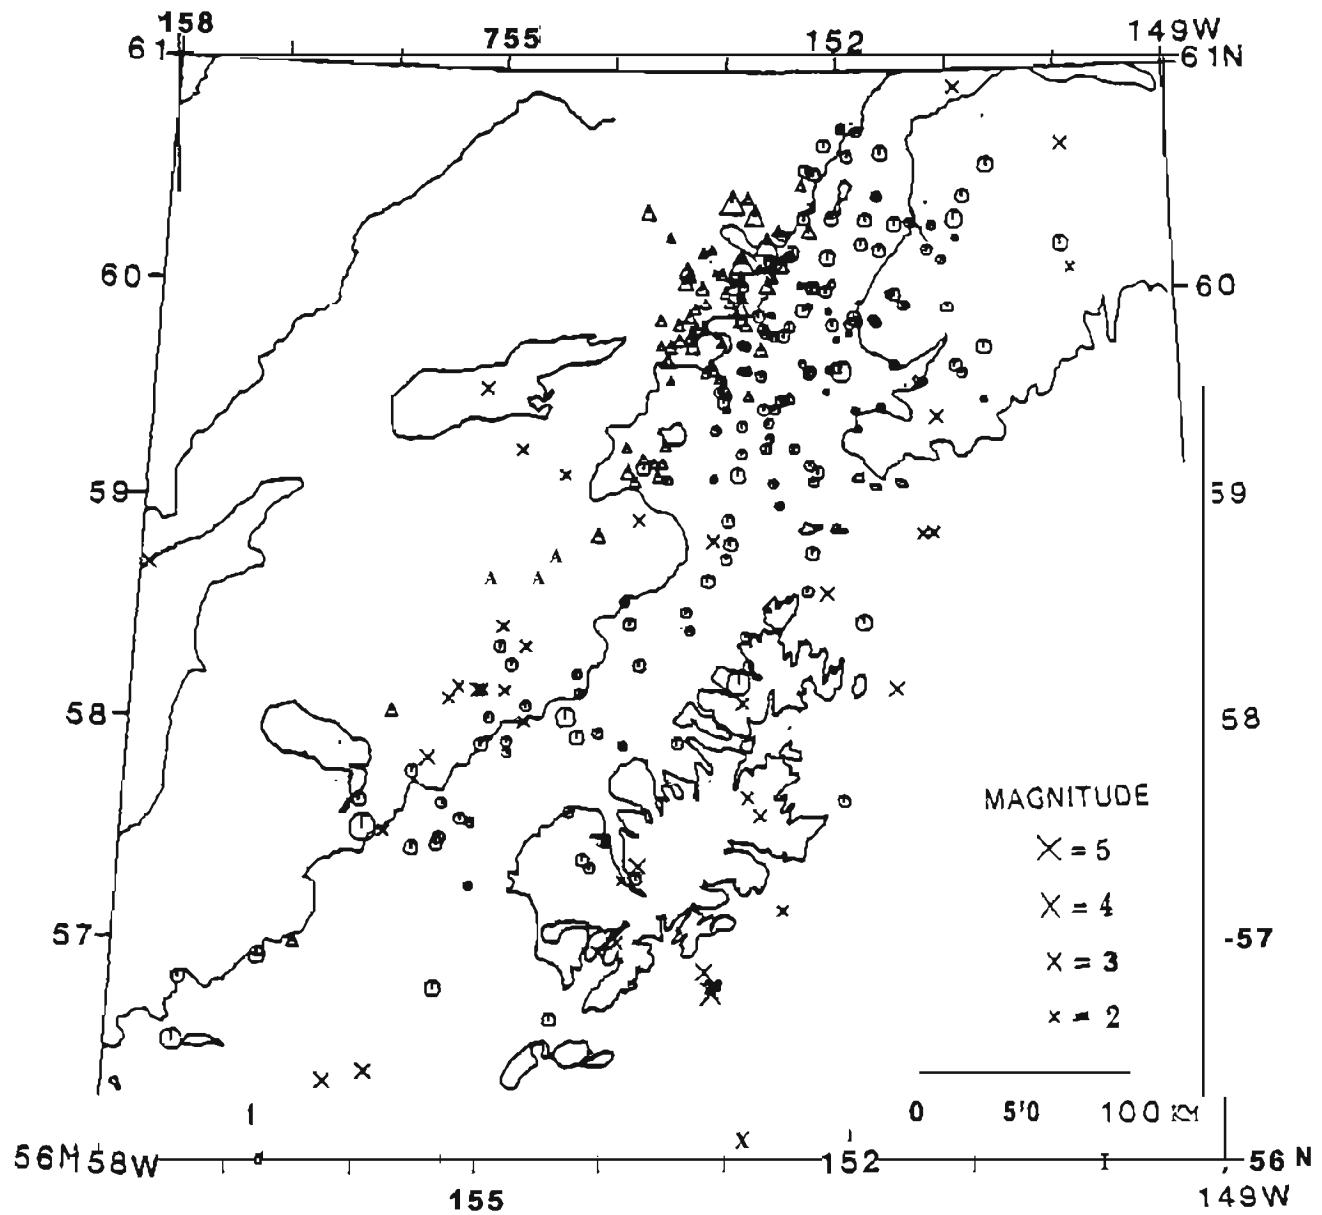

Figure 4: Epicenters of earthquakes south of 61°N located during the third quarter of 1983. Symbol size varies with magnitude as indicated. Different symbols are used for indicating depth range of earthquakes: \times for 0 to 35 km, \circ for 36 to 100 km, A for deeper than 100 km.

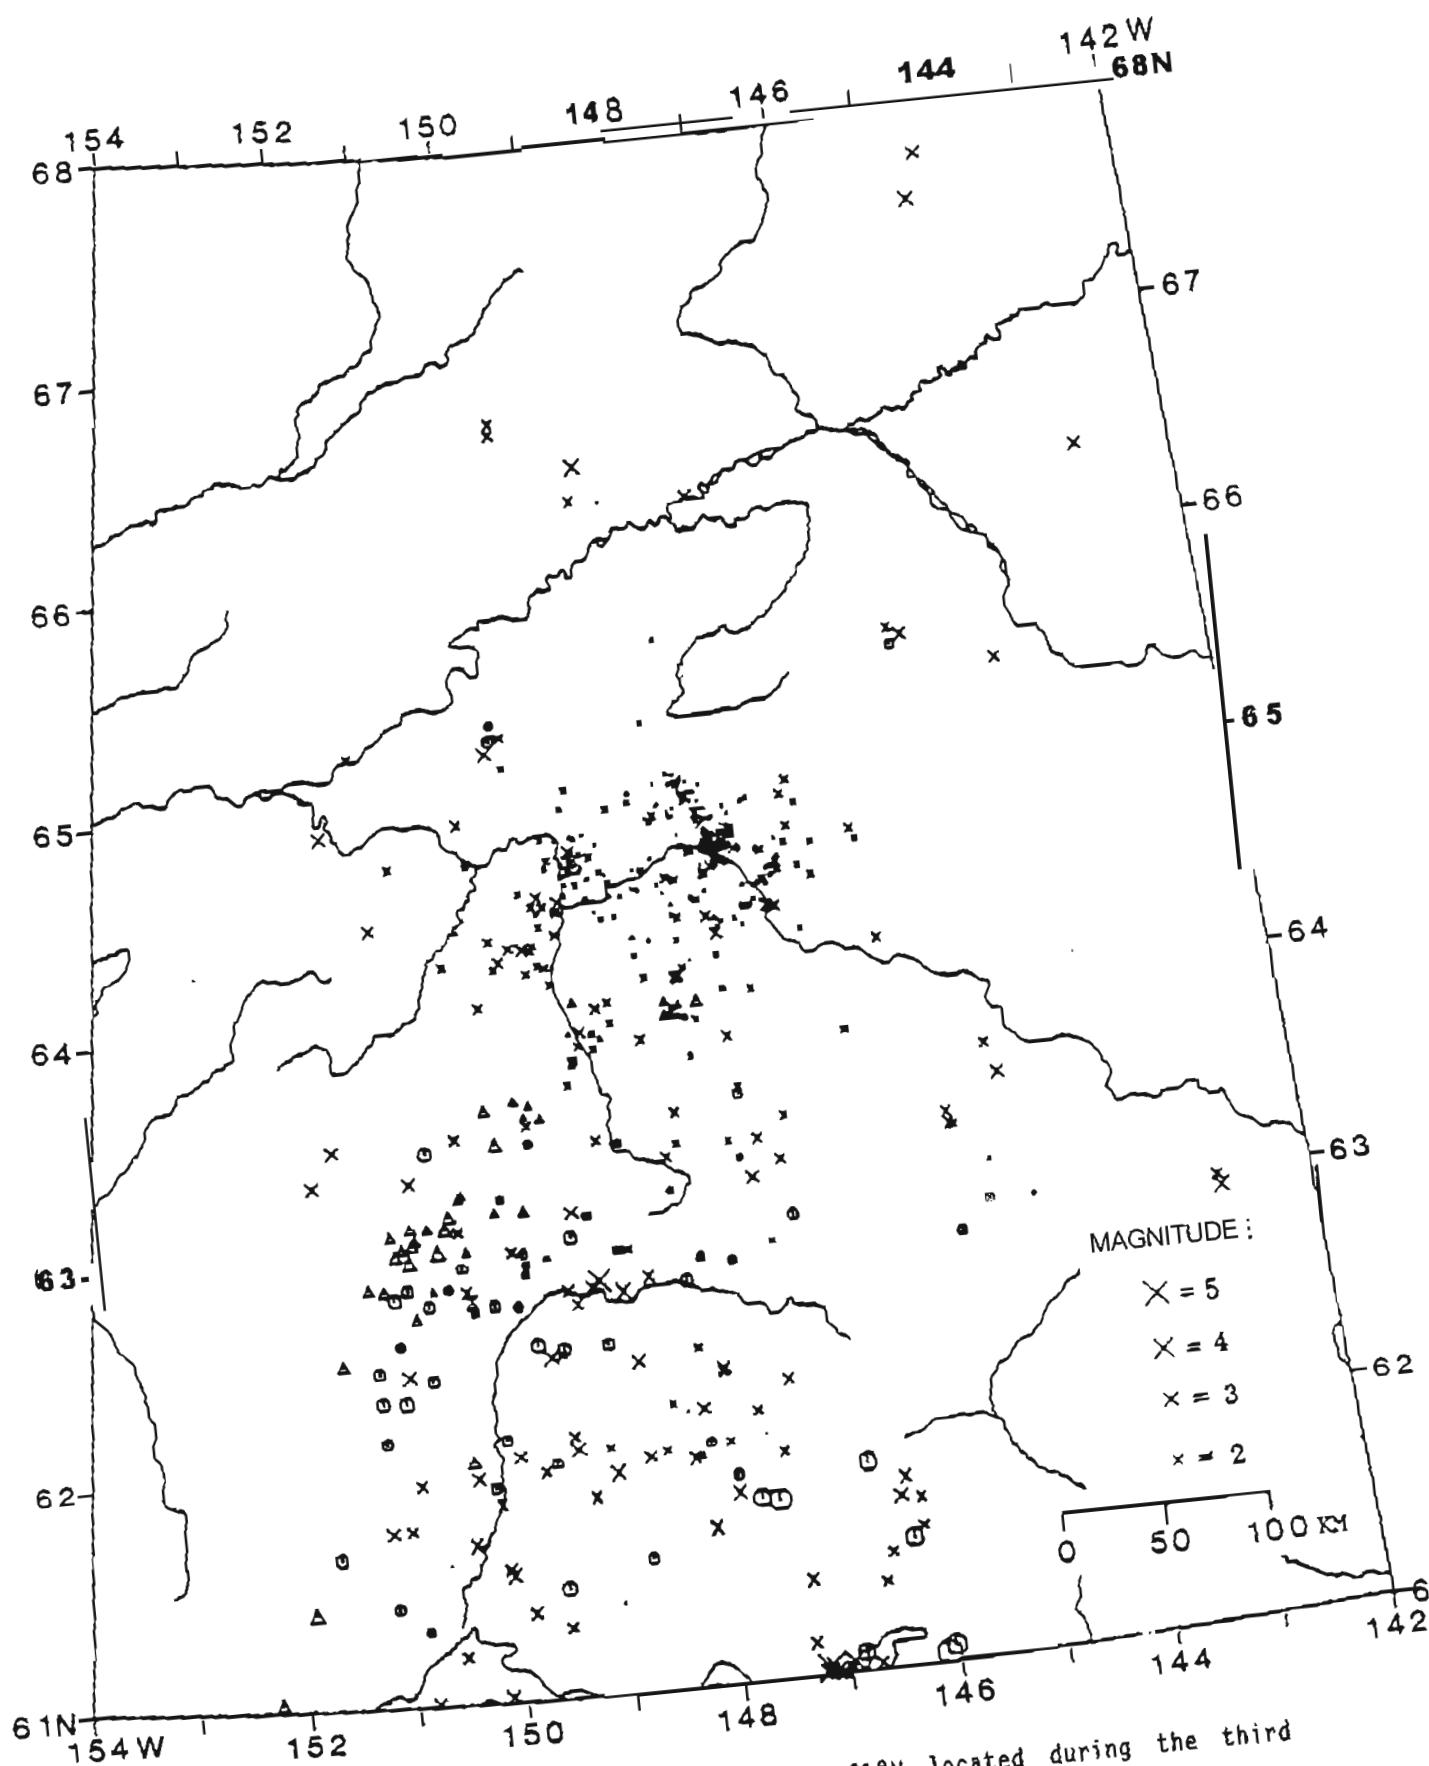

Figure 5: Epicenters of earthquakes north of 61°N located during the third quarter of 1983. Symbols as in figure 4.

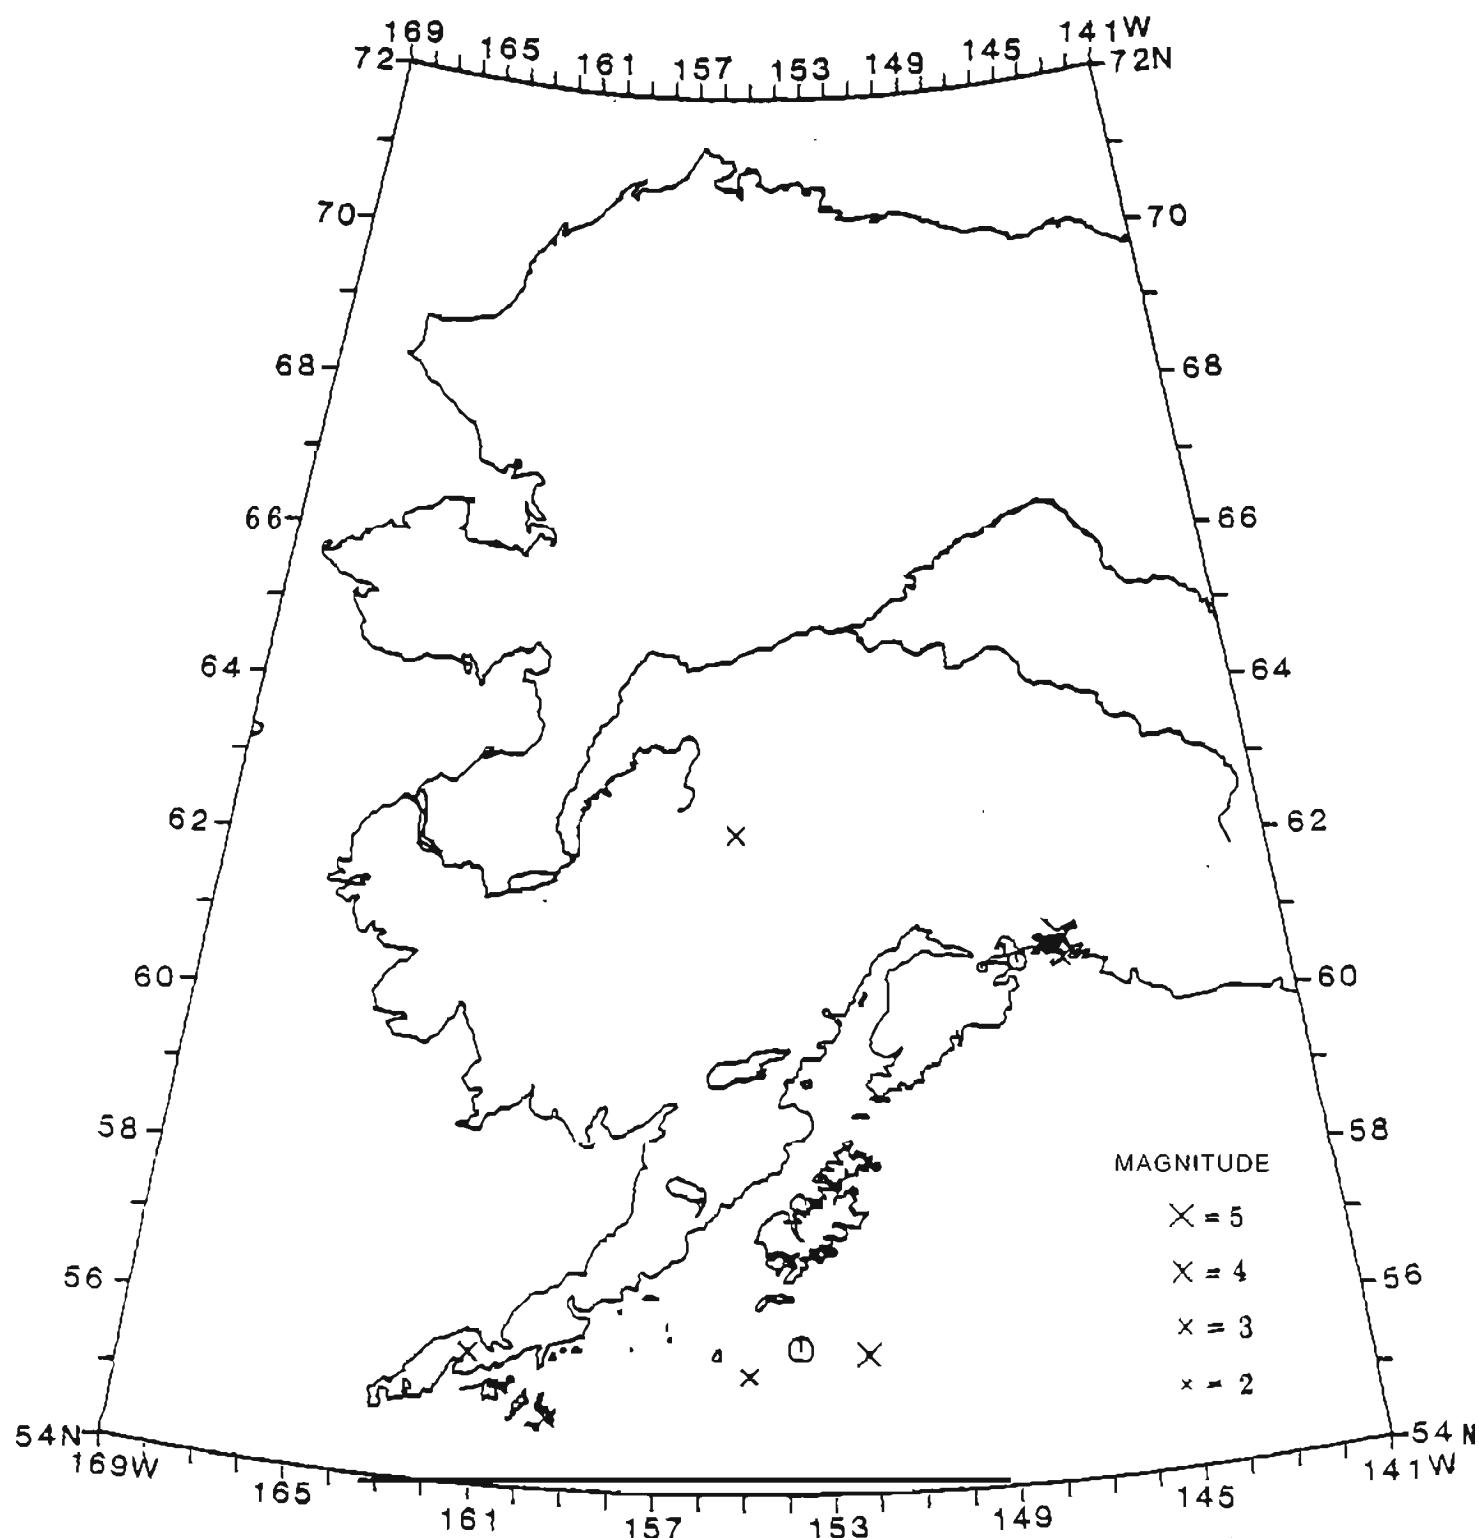

Figure 6: Epicenters of earthquakes located in the third quarter of 1983 and not shown in either Figure 4 or Figure 5. Symbols as in Figure 4.

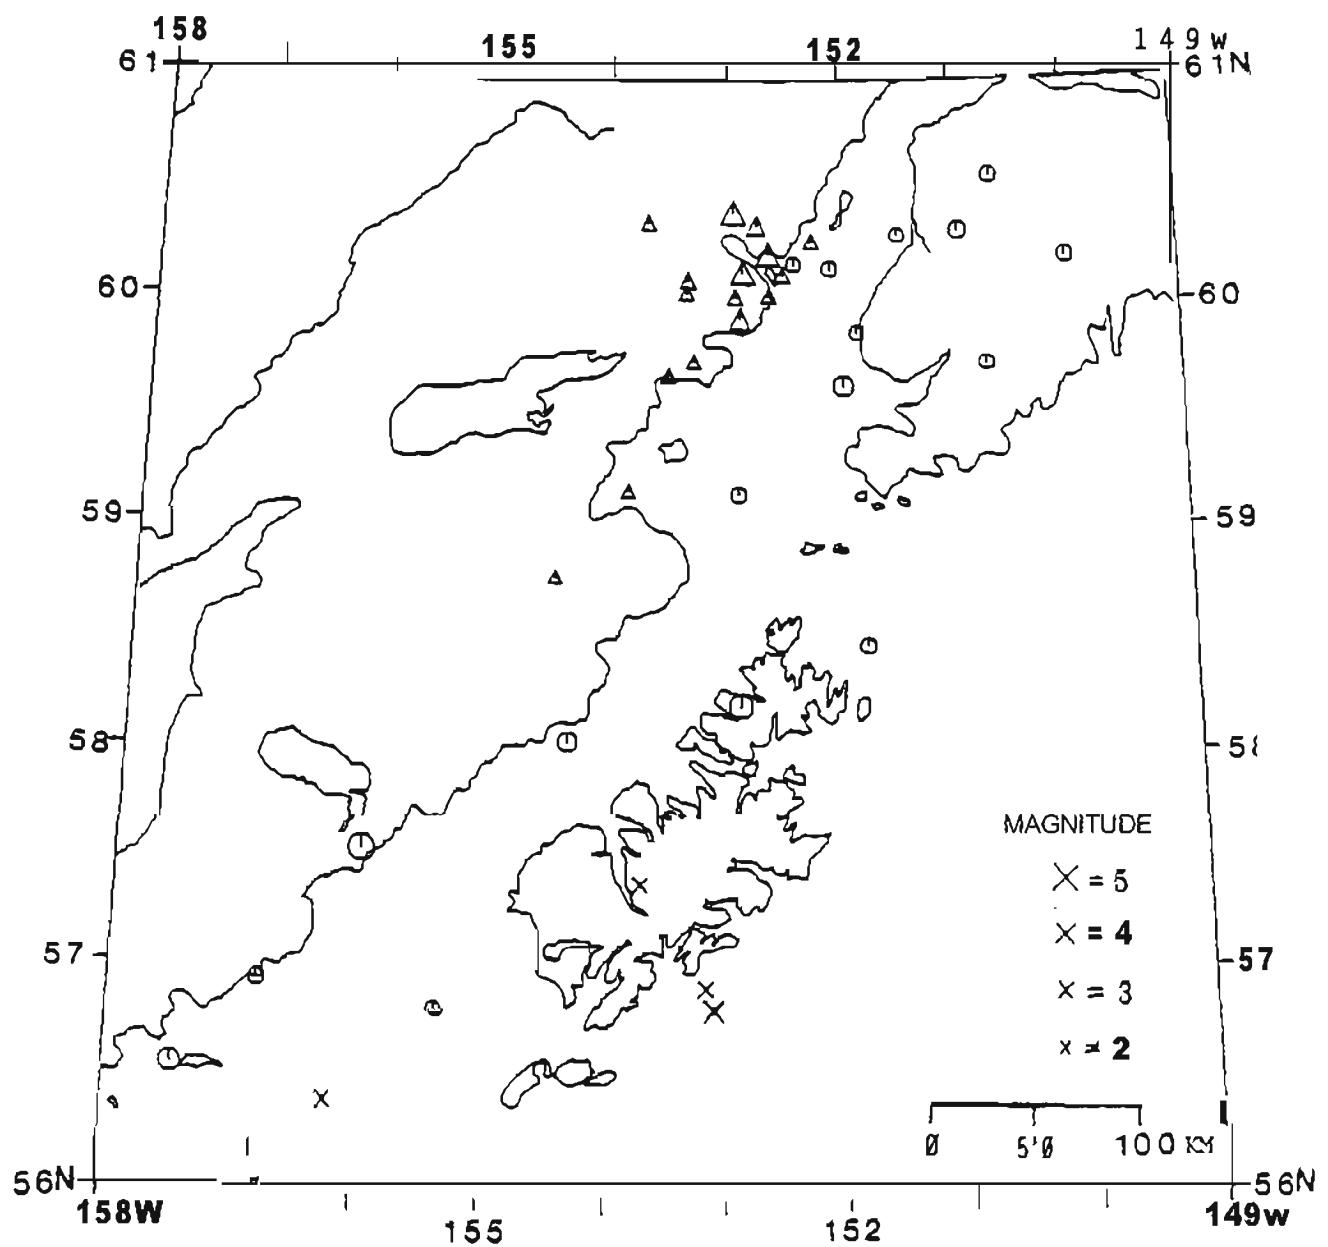

Figure 7: Epicenters of earthquakes of magnitude $M_L > 3$ south of $61^\circ N$ located during the third quarter of 1983. Symbols as in Figure 4.

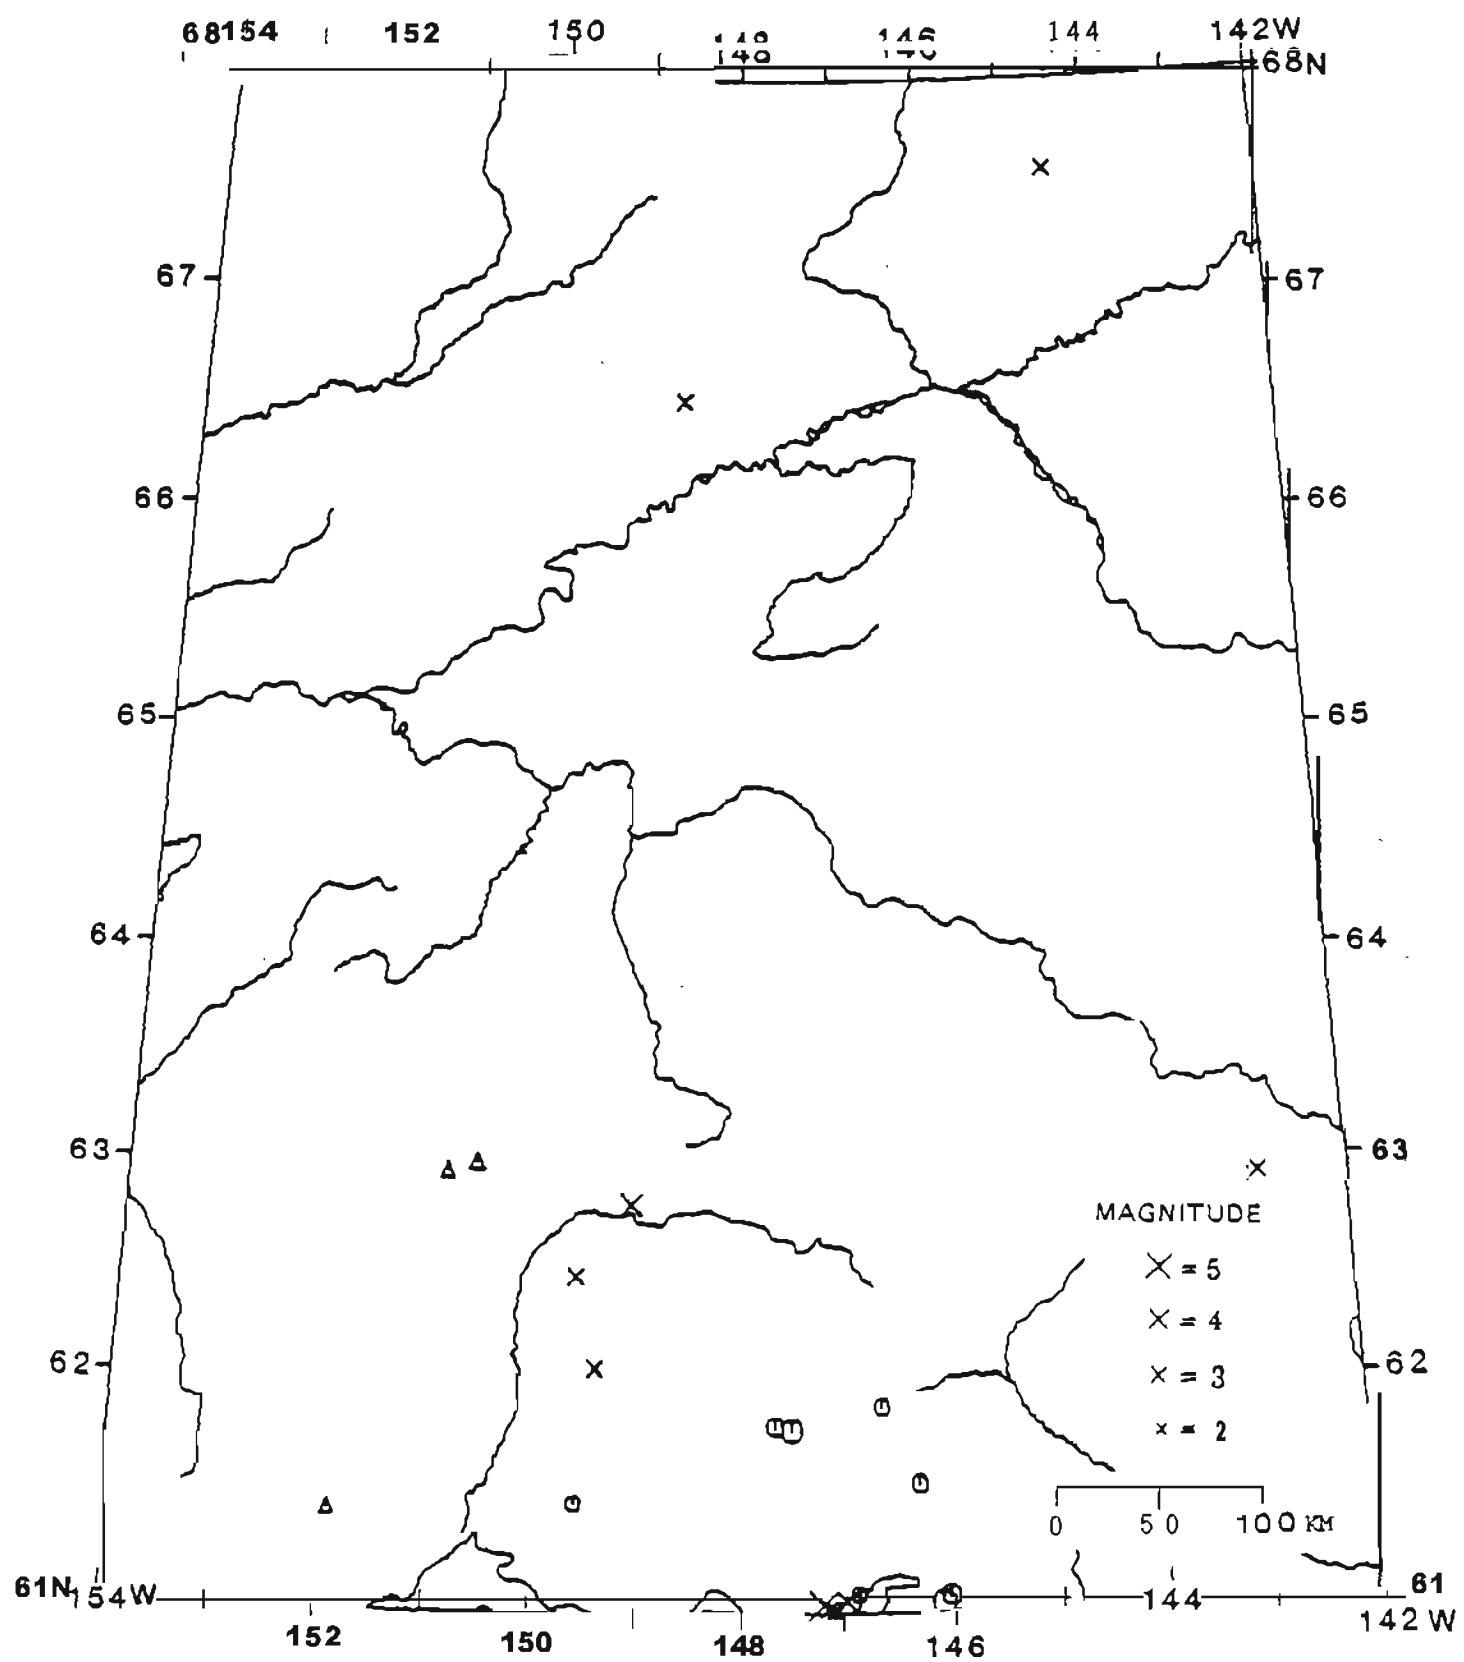

Figure 8: Epicenters of earthquakes of magnitude $M_l > 3$ north of $61^\circ N$ located during the third quarter of 1983. Symbols as in Figure 4.

capable of locating them or because a large number of station readings was available, a fact we thought useful to disseminate by incorporation into the catalog.

Detection threshold and quality of solution vary throughout the areas shown in Figures 4 through 6. For the areas of Figures 4 and 5 the catalog is probably complete for magnitudes larger than 3.0 to 3.5 (see Figure 7 and 8, respectively). As is apparent from Figure 1, station density varies considerably throughout these areas, and with it detection threshold levels.

The quality (i.e., reliability) of a hypocenter can be assessed from two sets of information provided in the listings for each earthquake: from the quality of the input data and from the results of certain statistical tests.

The number of P and S phases used in locating the earthquake (NP and NS, respectively in the listings), the largest azimuthal separation between stations as measured from the epicenter (GAP), and the distances from the epicenter to the closest and third closest station (D1, D3) are the most important aspects of the input data that control the hypocenter quality. A GAP of more than 180° means that the event lies outside the network and locations will be less reliable. Also, the higher the ratio of D1 to hypocentral depth is above unity the less reliable will be the depth of the event. Considering the unevenness of station coverage indicated in Figure 1, it is clear that the potential for high quality solutions varies greatly throughout the area of the figure.

The root-mean-square travel-time residual (RMS) and the horizontal (ERH) and vertical (ERZ) projections of the maximum axes of the one-standard-deviation confidence ellipsoid reflect the relative accuracy of the solution.

Since we use fairly simplified velocity models, it is likely that the RMS residuals measure primarily the incompatibility of these models and only secondarily random reading errors and phase misidentifications. While ERH and ERZ measure, respectively, the precision of epicenter and depth fairly well, it

is difficult to say what the absolute accuracy of the locations is, since we lack the proper calibration events (explosions) to perform studies in that regard.

The seismicity south of 61°N (Figure 4) is dominated by the subduction of the North Pacific plate beneath the North American plate. A well-defined Benioff zone dips below Cook Inlet and the Alaska Peninsula in a generally north-westerly direction with a dip of approximately 45 degrees. The relatively high level of seismic activity near 60°N at depths larger than about 70 km is a persistent feature of the area. The Benioff zone also dominates the seismicity of the southern portion of Figure 5 and terminates at about 64°N. A cluster of intermediate depth (> 50 km) seismicity near 63°N, below Mt. McKinley (Denali), is also a static feature of the seismicity of the area and pinpoints the region where the strike of the Benioff zone changes from north-northeasterly towards a more northeasterly direction. It should be noted that because of the large station spacing, the depth resolution of the hypocenters is rather poor between 62°N and 63°N. The cluster of shallow-depth earthquakes near Fairbanks is a long-term feature of the central Alaskan seismicity. While the relatively great station density near Fairbanks provides the lowest detection threshold throughout the network (with the exception of Augustine Volcano) the concentration of epicenters is indicative of a seismically very active zone.

The largest events to occur during the period were two shallow depth earthquakes in the vicinity of Columbia Bay in Prince William Sound. The first of these took place on July 12 and had a magnitude mb = 6.1. It was felt with intensity VI and caused slight damage in Valdez, 45 km to the east of the epicenter. The second event on September 7, had a magnitude mb = 6.0 and its epicenter was within approximately 10 km of the first event. It too caused slight damage in Valdez. The two events triggered several strong

motion instruments in Anchorage and Valdez, the second event generated a peak acceleration of .32 g at 45 km distance from the epicenter. This is apparently the largest instrumentally recorded peak acceleration recorded in Alaska.

Numerous aftershocks were associated with these two events but we located only a few of these since the events lie outside our network. The USGS operates a regional seismic network in that area and is therefore capable of locating these events very well. Other events with magnitude $ML > 5$ that occurred during this period were two magnitude $ML = 5.2$ earthquakes of intermediate depth (149 km and 118 km) below Iliamna Volcano and two events ($ML = 5.2$ and $ML = 5.4$) off the southwest coast of Kodiak Island.

ACKNOWLEDGEMENTS

We thank Tom Sokolowski and the staff of the NOAA Tsunami Warning System in Palmer for permitting and helping us to record several of their station signals on a continuous basis. We also thank John Lahr of the USGS for sharing several of his station signals with us and also for providing us with the HYPOELLIPE computer program.

The operation of the seismic networks and the preparation of this report were made possible by grants from the Division of Geological and Geophysical Surveys of the State of Alaska and by support from the Geophysical Institute of the University of Alaska. We are especially grateful to John Davies of the Division of Geological and Geophysics Surveys for his continued support.

APPENDIX

Catalog Format

Earthquakes are listed in chronological order. The following data are given for each event:

- (1) ORIGIN TIME in Universal Time (UT): date, hour (HR), minute (MN), and second (SEC). To convert to Alaska Standard Time (AST) subtract nine hours.
- (2) LAT N, LONG W: epicenter in degrees and minutes of north latitude and west longitude.
- (3) DEPTH, depth of focus in kilometers.
- (4) MAG, magnitude from maximum trace amplitude.
- (5) NP, number of P arrivals used in locating earthquake.
- (6) NS, number of S arrivals used in locating earthquake.
- (7) GAP, largest azimuthal separation in degrees between stations.
- (8) Ø1, distance in kilometers to the closest station to the epicenter.
- (9) Ø3, distance in kilometers to the third closest station to the epicenter.
- (10) RMS, root-mean-square error in seconds of the travel time residuals:

$$RMS = \sqrt{\sum_i (R_{P,i}^2 + R_{S,i}^2) / (NP + NS)}$$

where $R_{P,i}$ and $R_{S,i}$ are the observed minus the computed arrival times of P- and S-waves respectively at the i-th station.

- (11) ERH, largest horizontal deviation in kilometers from the hypocenter within the one-standard-deviation confidence ellipsoid. The quantity is a measure of the epicentral precision for an event. Values of ERH that exceed 99 km are tabulated as 99 km.
- (12) ERZ, largest vertical deviation in kilometers from the hypocenter within the one-standard deviation confidence ellipsoid. This quantity is a measure of the depth precision of the event. Values of ERZ that exceed 99 km are listed as 99 km.
- (13) Q, Quality of the hypocenter. This index is a measure of the precision of the hypocenters and reflects both the quality of the input data and the solution. These qualities are determined as follows:

Solution Quality	RMS	ERH	ERZ
A	< .15	< 1.0	< 2.0
B	< .30	< 2.5	< 5.0
C	< .50	< 5.0	
D	others		

Data Quality	NP + NS	GAP	D1
A	> 6	< 90	< depth or 5 km
B	> 6	< 135	< 2*depth or 10 km
C	> 6	< 180	< 50 km
D	others		

Q in the average (rounded to the poorer quality) of the solution and the data qualities.

MODIFIED MERCALLI SCALE, 1956 VERSION

- I. Not felt. Some very low frequency effects, such as seiching in lakes, may be observed resulting from large, distinct earthquakes.
- II. Felt by persons at rest, on upper floors, or favorably placed.
- III. Felt indoors. Hanging objects swing. Vibration like passing of light trucks. Duration estimated. May not be recognized as an earthquake.
- IV. Hanging objects swing. Vibration like passing of heavy trucks; or sensation of a jolt like a heavy ball striking the walls. Standing motor cars rock. Windows, dishes, doors rattle. Glasses clink. Crockery clashes. In the upper range of IV wooden walls and frame creak.
- V. Felt outdoors; direction estimated. Sleepers wakened. Liquids disturbed, some spilled. Small unstable objects displaced or upset. Doors swing, close, open. Shutters pictures move. Pendulum clocks stop, start, change rate.
- VI. Felt by all. Many frightened and run outdoors. Persons walk unsteadily. Windows, dishes, glassware broken. Knickknacks, books, etc., off shelves. Pictures off walls. Furniture moved or overturned. Weak plaster and masonry Ø cracked. Small bells ring (church, school). Trees, bushes shaken (visibly, or heard to rustle--CFR).
- VII. Difficult to stand, flattened by drivers of motor cars. Hanging objects quiver. Furniture broken. Damage to masonry Ø, including cracks. Weak chimneys broken at roof line. Fall of plaster, loose bricks, stones, tiles, cornices (also unbraced parapets and architectural ornaments--CFR). Some cracks in masonry C. Waves on ponds; water turbid with mud. Small slides and caving in along sand or gravel banks. Large bells ring. Concrete irrigation ditches damaged.
- VIII. Steering of motor cars affected. Damage to masonry C; partial collapse. Some damage to masonry B; none to masonry A. Fall of stucco and some masonry walls. Twisting, fall of chimneys, factory stacks, monuments, towers, elevated tanks. Frame houses moved on foundations if not bolted down; loose panel walls thrown out. Decayed piling broken off. Branches broken from trees. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes.
- IX. General panic. Masonry Ø destroyed; masonry C heavily damaged, sometimes with complete collapse; masonry B seriously damaged. (General damage to foundations--CFR.) Frame structures, if not bolted, shifted off foundations. Frames racked. Serious damage to reservoirs. Underground pipes broken. Conspicuous cracks in ground. In alluviated areas sand and mud ejected, earthquake fountains, sand craters.
- X. Most masonry and frame structures destroyed with their foundations. Some well-built wooden structures and bridges destroyed. Serious damage to dams, dikes, embankments. Large landslides. Water thrown on banks of canals, rivers, lakes, etc. Sand and mud shifted horizontally on beaches and flat land. Rails bent slightly.
- XI. Rails bent greatly. Underground pipelines completely out of service.
- XII. Damage nearly total. Large rock masses displaced. Lines of sight and level distorted. Objects thrown into the air.

Note: CFR in parentheses refers to supplemental comments by Charles F. Richter.
