## National Marine Fisheries Service, Special Scientific Report-Fisheries

The major responsibilities of the National Marine Fisheries Service (NMFS) are to monitor and assess the abundance and geographic distribution of fishery resources, to understand and predict fluctuations in the quantity and distribution of these resources, and to establish levels for optimum use of the resources. NMFS is also charged with the development and implementation of policies for managing national fishing grounds, development and enforcement of domestic fisheries regulations, surveillance of foreign fishing off United States coastal waters, and the development and enforcement of international fishery agreements and policies. NMFS also assists the fishing industry through marketing service and economic analysis programs, and mortgage insurance and vessel construction subsidies. It collects, analyzes, and publishes statistics on various phases of the industry.

The Special Scientific Report-Fisheries series was established in 1949. The series carries reports on scientific investigations that document long-term continuing programs of NMFS, or intensive scientific reports on studies of restricted scope. The reports may deal with applied fishery problems. The series is also used as a medium for the publication of bibliographies of a specialized scientific nature.

NOAA Technical Reports NMFS SSRF are available free in limited numbers to governmental agencies, both Federal and State. They are also available in exchange for other scientific and technical publications in the marine sciences. Individual copies may be obtained (unless otherwise noted) from D825, Technical Information Division, Environmental Science Information Center, NOAA, Washington, D.C. 20235. Recent SSRFs are:

WILLIAM R. NICHOLSON ${ }^{1}$

#### Abstract

The menhaden purse seine fishery in the Gulf of Mexico, primarily for Gulf menhaden, Brevoortia patronus, extends from about early April to early October. From 1964 to 1973 the catch fluctuated between 317,000 and $728,000 \mathrm{t}$ and the number of vessels ranged from 65 to 82 . Larger and faster refrigerated vessels replaced most of the smaller nonrefrigerated vessels and modern methods of fishing were adopted. Population levels were high and there were no large fluctuations in year class abundance. Age-1 and -2 fish supplied from 95 to $99 \%$ of the catch by weight. Over $97 \%$ of the fish were between 120 and 225 mm fork length. The mean age and size generally were slightly greater in the center of the fishery (central and eastern Louisiana) than in the eastern (Mississippi) and western areas (western Louisiana and Texas). Mean age decreased as the season progressed.

## INTRODUCTION

The menhaden purse seine fishery in the Gulf of Mexico, dating prior to 1900 , underwent a rapid expansion after World War II. New plants for processing meal and oil were built and larger and more modern vessels were added to the fleet. By 1964 the annual catch had risen to $410,000 \mathrm{t}$, a 10 -fold increase over the 1946 catch.

Although three species of menhaden inhabit the area, only the Gulf menhaden, Brevoortia patronus, is important to the fishery. Yellowfin menhaden, B. smithi, occurs east of the Mississippi delta, and finescale menhaden, B. gunteri, west of the delta (Christmas and Gunter 1960). These two species together, however, probably supply, on the basis of numbers observed in catches or found in catch samples, less than $1 \%$ of the menhaden processed.
Because of general concern that the resource would be overfished and that catches would undergo a decline similar to that of Atlantic menhaden, B. tyrannus, an investigation was begun in 1964 by the National Marine Fisheries Service and centered at the Beaufort, N.C., laboratory. Many of the procedures and techniques developed for collecting and compiling information on the Atlantic menhaden fishery were followed. Catches of individual vessels dating from 1945 were compiled from confidential company records, and information on improvements in fishing methods, such as the use of spotter planes, fish pumps, and power blocks, were collected. A systematic sampling of catches for age, size, and sex was begun in 1964 and still continues.

The purpose of this paper is to document changes that have occurred in the fishery, update records of landings,

[^0]describe methods of sampling the catch and estimating the number of fish landed at each age, and discuss differences or similarities in age and size composition of catches throughout the fishery. Some preliminary data on catches, number of vessels and airplanes, and age composition of catches have been published in annual reports of the Beaufort Laboratory and by Chapoton (1972). Previous reports on age composition, however, were inaccurate, particularly for the years 1964-69, because a majority of fish had been over-aged during preliminary aging procedures. Subsequent reading showed a greater number of age-1 fish, fewer fish over age-2, and none over age-3.

## THE FISHERY

Although a menhaden fishery has existed along the Gulf coast since the late 1800's, records of catches, the location and number of plants, and the number and types of vessels before 1946 are fragmentary. One plant is known to have operated in Texas from around the turn of the century until at least 1923. Another operated intermittently in the vicinity of Port St. Joe and Apalachicola, Fla., from at least 1918 until 1961. Another operated in the Pascagoula, Miss., area from sometime in the 1930's until 1959.

The modern purse seine fishery began after World War II as the world demand for fish meal and oil increased. Fishing usually begins in April and ends in early October. The first plant in Louisiana opened in 1946. In the next few years additional plants were built in Mississippi, Louisiana, and Texas (Fig. 1). Since 1950 the number of plants operating each year has fluctuated between 9 and 13 (Table 1), with some plants being closed or destroyed and new ones being built. The general trend has been toward larger and more efficient plants.

${ }^{1}$ Number of vessels that landed fish 9 or more weeks.

## Distribution of Fishing

From 1964 to 1969 logbooks and maps were placed aboard vessels and the captain or pilot was asked to record, among other things, the location of each purse seine set. Squares on the maps, formed by even degrees
of latitude and longitude, were divided by 10 minute intervals into 36 subareas, identified by a letter (A to F) and a number ( 1 to 6 ). The location of a given set could be referenced within a $100 \mathrm{mi}^{2}$ subarea, identified by latitude, longitude, and subarea (for example 29-84-B2). Although all vessels did not keep logs and some kept only
partial records, the locations of over 48,000 sets were recorded for the $6-\mathrm{yr}$ period.

To show the relative distribution of fishing activity, particularly in reference to distance from shore, I organized the data by degrees of longitude to show the percentage of sets made less than $10,20,30$, and 40 mi from shore (Table 2). Since longitude 89 is divided by the Mississippi Delta, I treated the data from east of the delta (89a) and west of the delta (89b) separately. West of the Mississippi delta (longitudes 89b-94), 44 to $93 \%$ of the sets were less than 10 mi from shore, 90 to $98 \%$ less than 20 mi , and 99 to $100 \%$ less than 30 mi . East of the delta (longitudes $84-89 \mathrm{a}$ ), $100 \%$ of the sets were made less than 10 mi from shore.

In effect, the fishing area west of the delta is restricted to a narrower band adjacent to shore than is indicated by the data. Because the shoreline usually passes through subareas rather than along their boundaries, the actual distances from shore are considerably less than the maximum. Therefore, a majority of the sets are in reality less than the maximum possible distance. Probably 85 to $90 \%$ are made within 15 mi of shore. Undoubtedly many reported in subareas more than 20 mi were due to errors in recording.

## Catches

Records of annual catches were compiled from confidential company sources of individual vessel landings for years 1945-73 (Table 3). In a few cases where plant records were missing (one plant in Mississippi 1949-50, one plant in Louisiana 1954-55, and one plant in Texas 1948-51), I estimated catches by multiplying the mean catch of similar vessels at nearby plants by the number of vessels that normally fished at plants whose records were missing. For Florida in 1946-47 and Mississippi in 1946 where only one plant operated, I was unable, however, to make any estimates and no published records were available.

Published records (Anonymous 1918-38, 1939-44) prior to 1945, although fragmentary and incomplete, suggest annual landings from 1918 to 1944 of about 2,000 to $12,-$ 000 t , all in Florida, Mississippi, or Texas. There was litthe increase until 1948, when the catch was $103,000 \mathrm{t}$, mainly as a result of new plants being built in Mississippi, Louisiana, and Texas. It had increased to $481,000 \mathrm{t}$ by 1962 and thereafter fluctuated between 317,000 and 728,-

'Records not available.

000 t . More vessels, larger and more efficient vessels, and improved fishing technology were primarily responsible for increased catches after 1947.

## Size and Number of Vessels

The number of vessels increased rapidly from 1945 to 1950, and then more slowly, reached a peak of 82 in 1965, and thereafter fluctuated between 65 and 82 (Table 1). Because many vessels often made only a few landings each year in the early years of the fishery, I have excluded all vessels that fished less than 9 wk . Including them would have indicated greater changes in the composition of the fleet than actually occurred.

The shift to larger vessels of greater carrying capacity was the most striking change. Vessels less than 75 net tons constituted over $50 \%$ of the fleet until 1956. In the following years the number of vessels in this size class declined continually, dropping to 1 in 1966 and finally disappearing completely in 1972. The number of vessels between 75 and 200 net tons increased until 1960, remained fairly stable through 1964, and then declined steadily. By 1973 they composed only $22 \%$ of the fleet. Vessels over 200 net tons first appeared in 1955, increased gradually over the years, and by 1973 numbered 51 , or $78 \%$ of the fleet. Most of the vessels in this size class after 1965 were greater than 300 net tons, and one was more than 400 net tons.

## Improvements in Fishing Methods

Fish pumps, power blocks, refrigeration, nylon purse seines, aluminum purse boats, and airplane spotting were introduced in the Gulf menhaden fishery in the 1950's (Table 1). These techniques and equipment increased efficiency by reducing the time spent searching for fish, steaming to and from fishing grounds, and completing purse seine sets.
Fish pumps replaced the time-consuming method of brailing fish from the purse seine to the hold of the carrier vessel-(Robas 1959), and first appeared on gulf coast vessels in 1951. By 1960 they were standard equipment on nearly all vessels.

A power block is a mechanical device that retrieves the net and concentrates the fish in it so they may be pumped or brailed aboard the carrier vessel. Its use reduces the average time required to concentrate the fish by about 6 min and the crew by 6 to 10 men (Schmidt 1959a, b), and permits a quick retrieval of the net if a school of fish is missed. Power blocks were introduced in
the Gulf menhaden fishery in 1956. Although their use did not spread rapidly, they were standard equipment on over $80 \%$ of the vessels by 1964 .

Refrigerated vessels are able to fish greater distances from their home ports and to spend up to a week on the fishing grounds. Generally larger than nonrefrigerated vessels, they increased steadily in number after their introduction in 1957. Their use has been more extensive in the central and eastern Gulf regions, where vessels travel farther to the fishing grounds, than in the western Gulf.

Aluminum purse boats can encircle a school of fish faster and can operate in rougher waters better than wooden or steel boats. They were first employed in 1956, but their use spread slowly, and all vessels were not equipped with aluminum purse boats until about 1970.
Information was difficult to obtain on the use of nylon seines by individual vessels. A few were reported to have used them in 1956. The changeover was rapid in 1957 and 1958, and by 1959 nearly all vessels were using them.
The use of airplanes for locating schools of menhaden greatly reduced the amount of vessel searching time and was one of the more important improvements in fishing methods. Spotter planes were introduced in the Gulf menhaden fishery in 1949 and rapidly increased in number. Most plants chartered planes part time until about 1955, but employed two to four planes full time by 1960. Initially, planes only guided vessels to large concentrations of fish, but in recent years pilots have used twoway radios to direct the purse boats in setting the seine.

## SAMPLING PROCEDURE

Catches of Gulf menhaden were sampled by seasonal employees who followed the procedures described for sampling catches of Atlantic menhaden (June and Reintjes 1960). For each vessel sampled, fish were taken

${ }^{1}$ Plant did not operate:
from the top of the catch, which came from the last set made by the vessel, measured (millimeters, fork length), weighed (grams), and sexed. Scales were taken for aging (Nicholson and Schaaf in press). In 1964, 1965, and 1971, two samples of 20 fish ( 1 sample per boat) were taken daily. From 1966 to 1970, three samples of 20 fish were taken. Beginning in 1972, three samples of 10 fish each were taken. The location of the last set made by the vessel was recorded to the nearest 10 minutes of latitude and longitude.

All plants were not sampled equally. Usually, four samplers were employed and stationed at locations where they could cover two or more plants, arbitrarily grouped into ports. Locations were chosen so that plants throughout the entire range of the fishery could be sampled. The number of samples depended, in part, on the duty station of the sampler and ranged from 0 to over 150 per plant and from 386 to 1,004 per year (Table 4).

## AGE AND SIZE COMPOSITION

The number of fish landed at each plant was estimated by dividing the total weight of fish landed weekly by the mean weight of fish in the weekly samples, either from that plant or from several plants arbitrarily grouped together. The number of each age was estimated by multiplying the total estimated number of fish by the percentage of each age in the samples. Weekly estimates were summed to obtain seasonal estimates. Since fish landed at plants in the eastern and western ends of the fishery tended to be smaller and younger than fish landed at plants in the middle, I summarized the data by grouping together plants in the eastern area (Mississippi and Florida), central area (Empire to Intracoastal City, La.), and western area (Cameron, La., and Sabine Pass, Tex.).

The total number of fish landed annually varied from 4,054.73 million in 1966 to $7,796.38$ million in 1971 (Table 5). Age-1 and -2 fish together supplied from 97 to $99 \%$ of the fish caught, and ages 0 and 3 supplied the remainder. Age- 1 fish supplied from 59 to $92 \%$ of the estimated number of fish caught annually, while age- 2 fish supplied from 6 to $40 \%$. These percentages are about the same, whether they are calculated from the estimated number of fish caught or from the number of fish in the samples (Table 6). The former method of calculating is more precise, since it corrects for differences in time and space between the ratio of weight of fish landed to number of fish in the samples.

There was remarkable little variation from year to year in the length range or mean length, either for individual ages or for all ages combined (Table 7). With few exceptions length ranged from about 115 to 215 mm . Mean annual lengths ranged from 147 to 165 mm for age- 1 fish, 181 to 188 mm for age- 2,201 to 214 mm for fish over age2, and 153 to 172 mm for all ages combined.

Weight also showed relatively little annual variation, ranging from about 20 to 250 g (Table 7). Means ranged from 65 to 101 g for age- 1 fish, 122 to 148 g for age- 2,170

Table 5.-Estimated number (in millions) of Gulf menhaden at each age landed annually, 1964-73, at plants in eastern area (Mississippi and Florida), central area (Empire to Intracoastal City, La.), and western area (Cameron, La., and Sabine Pass, Tex.).

to 217 g for fish over age-2, and 74 to 117 g for all ages combined.
The contribution of each age group to the total weight of the catch was estimated by multiplying the number of fish caught at each age by the mean weight of fish in the samples. Two age groups, 1 and 2, accounted for over $95 \%$ of the total weight of the catch. The annual variation ranged from 95.0 to $99.3 \%$. Age-1 fish contributed from 49 to $88 \%$, and averaged $63 \%$ for the $10-\mathrm{yr}$ period. Age-2 fish contributed from 12 to $50 \%$ and averaged $34 \%$. Age-3 fish contributed an average of $2.6 \%$, and age- 0 fish $0.2 \%$ (Table 8).

## AGE AND SIZE DISTRIBUTION BY LONGITUDE

To determine if fish were stratified by age and size along an east-west axis, I calculated the mean age and mean length of each age for each degree of longitude (dividing 89 into two parts: 89a east and 89b west of the delta) by month and year. For summarizing mean lengths I combined all months; for summarizing mean ages I grouped longitudes into three areas: eastern (8489a), central (89b-91), and western (92-94). Too few samples were obtained from longitudes $84^{\circ}-87^{\circ}$ and $94^{\circ}$ to calculate useful mean lengths for each longitude.

There were some differences in mean lengths by longitude, but they were small and not consistant for either age - 1 or -2 , although $10-\mathrm{yr}$ means of age- 2 fish were slightly greater for central longitudes (89b-91) than for the others (Table 9). Monthly means showed no trends.

The mean age tended to be highest in the central area and lowest in the western (Table 10). In all years it was

lowest in the western area. In 6 of 10 yr it was higher in the central than in the eastern area and in the other 4 yr it was about the same in both areas. In 1967, when the mean age was about the same in all areas, the fishery was dominated by the 1966 year class, which composed $92 \%$ of the fish caught. Monthly means generally declined as the season progressed.

Mean lengths and weights of all ages combined also tended to be greater in the center of the fishing area, since mean ages were greater and catches contained a higher proportion of older, larger fish. The variation was similar to, but less than that for mean ages. Monthly means showed similar trends.

At ports in the center of the fishery (Empire to Intracoastal City) mean lengths were greater than at ports in
the eastern (Moss Pt.) or western (Cameron) areas, and the percentage of age-1 fish in most cases was less (Table 11). The tendency of fish to be older and larger at ports in the center of the fishery probably reflects the tendency of vessels to fish most often in areas close to their home ports. The percentage of age- 1 fish tended to be greatest at Intracoastal City, the most western port in the central area, than at other ports in the central area, but smaller than at Cameron.

## RECRUITMENT AND RELATIVE ABUNDANCE

Fish usually enter the fishery at age-1 at a minimum size of about 120 mm , although some age- 0 fish enter at about the same size in September and October. Since some age- 1 fish are still less than 100 mm in July, as shown by catch samples, a year class probably is not fully recruited until August or September. The removal of large and the recruitment of small age-1 fish during the fishing season tends to supress the amount of increase in the mean and modal lengths during the fishing season relative to actual growth.

If age groups are distributed equally in time and space throughout a fishery and if the distribution of fishing effort does not change each year, the catch per unit of effort (CPUE) for each age group is an estimate of relative year class abundance. Since these conditions are closely approximated in the Gulf menhaden fishery, I based estimates of year class abundance on the CPUE of each age group. As a measure of effort, I used the adjusted vessel week ${ }^{2}$ which was calculated from the CPUE of a selected group of vessels and the total catch of all vessels.

For the period covered, there was relatively little variation in year class abundance (Table 12). The total CPUE of all ages in a year class combined ranged from 2.577 million fish per week for the 1965 year class to 5.377 million for the 1968 year class, with a mean of 3.742 million for all years. The most abundant year classes appeared to be the 1964, 1968, and 1970, the least abundant the 1965 and 1971. On the basis of the CPUE of age-2 fish only, the 1962 year class also was probably strong.

There also was little variation in overall abundance. The CPUE for total number of fish, regardless of age, averaged 3.63 million for the 10 yr and ranged from 2.95 (1973) to 4.60 million (1969). Years of greatest relative abundance were 1965, 1969, and 1971 (4.42, 4.60, and 4.38 million, respectively); years of least abundance were 1966, 1972, and 1973 ( $3.02,3.01$, and 2.95 million, respectively).

[^1]Table 12.-Catch per unit of effort (millions of fish) of Gulf menhaden, at each age, 1962-72 year classes.

| Year <br> class | Age 1 | Age 2 | Age 3 | Total |

## NOAA SCIENTIFIC AND TECHNICAL PUBLICATIONS

NOAA, the National Oceanic and Atmospheric Administration, was established as part of the Department of Commerce on October 3, 1970. The mission responsibilities of NOAA are to monitor and predict the state of the solid Earth, the oceans and their living resources, the atmosphere, and the space environment of the Earth, and to assess the socioeconomic impact of natural and technological changes in the environment.

The six Major Line Components of NOAA regularly produce various types of scientific and technical information in the following kinds of publications:

PROFESSIONAL PAPERS-Important definitive research results, major techniques, and special investigations.
TECHNICAL REPORTS—Journal quality with extensive details, mathematical developments, or data listings.
TECHNICAL MEMORANDUMS-Reports of preliminary, partial, or negative research or technology results, interim instructions, and the like.
CONTRACT AND GRANT REPORTS—Reports prepared by contractors or grantees under NOAA sponsorship.

TECHNICAL SERVICE PUBLICATIONSThese are publications containing data, observations, instructions, etc. A partial listing: Data serials; Prediction and outlook periodicals; Technical manuals, training papers, planning reports, and information serials: and Miscellaneous technical publications.

ATLAS-Analysed data generally presented in the form of maps showing distribution of rainfall, chemical and physical conditions of oceans and atmosphere, distribution of fishes and marine mammals, ionospheric conditions, etc.
