eers

Appendix A

Final DA Permit Application

- Notice of Availability
- Department of the Army Permit Application
- Preliminary Jurisdictional Wetland Determination

Note to Readers:

The Department of the Army 404/10 permit application and the Preliminary Jurisdictional Wetland Determination (PJD) provided in this appendix were developed by the Applicant. The Corps recognizes that there are minor quantitative differences in the description of the Applicant's proposed project (Alternative B in the Draft EIS) when compared to the permit application in this Appendix. These differences include things such as:

- Description of gravel infrastructure sizes
    - The Draft EIS used generalized gravel pad and gravel road footprints to allow for equal comparison of all alternatives, while the permit application and is based on more detailed engineering design
    - The Draft EIS and permit application/PJD delineate boundaries between pads and roads differently
- Footprint impacts of other infrastructure such as VSMs and trenches (the Draft EIS discusses general impacts whereas the permit application and PJD provide estimates based on more detailed engineering design)
- Wetland impacts (methodology differences in delineation of beginning/ending of roads and Applicant use of detailed vs. preliminary engineering design)

These differences reflect efforts by the Corps to clearly differentiate between various project components (e.g., roads from pads) to support the analysis of project impacts. The Corps believes that these differences are minor (the Applicant's pad footprints and road alignments were used in the EIS impact analysis) and that they do not substantively affect the impact analyses of the proposed action.

Additionally, the permit application, which was submitted on October 26, 2011 and reflects the Applicant's ongoing detailed engineering efforts, includes the potential addition of six temporary support piles at the sealift bulkhead. Analysis of this additional project component will be included in the Final EIS.

Alaska District**

Public Notice of Application for Permit

ANCHORAGE
Regulatory Division (1145)
CEPOA-RD
Post Office Box 6898
JBER, Alaska 99506-0898

PUBLIC NOTICE DATE: 18 November 2011

EXPIRATION DATE: 3 January 2012

REFERENCE NUMBER: POA-2001-1082-M1

WATERWAY: Beaufort Sea

The public in hereby notified a Department of the Army (DA) permit application has been received for proposed work in waters and navigable waters of the United States (US), including streams, wetlands, and marine waters, as described below and shown on the enclosed project drawings.

Comments on the described work noting US Army Corps of Engineers (USACE) file number POA-2001-1082-M1, Beaufort Sea, need to be submitted no later than the expiration date of this Public Notice (shown above) to become part of the administrative record and be considered in our permit decision. Please submit comments to the USACE Project Manager listed immediately below by the communication method of your choice.

USACE PROJECT MANAGER: **Harry A. Baij Jr.** Submit comments to the US Mail address above, by calling 907-753-2784 (office), 907-350-5097 (cell), toll free in Alaska at 800-478-2712, by fax at 907-753-5567, or by e-mail address at **harry.a.baij@usace.army.mil**. Comments and requests for information can be sent directly to Mr. Baij at the above e-mail address.

APPLICANT: Exxon Mobil Corporation and PTE Pipeline LLC.

APPLICANT'S AGENT: Mr. Lee Bruce, Senior Project Manager, Point Thomson Project, ExxonMobil Development Company (EMDC), a wholly-owned subsidiary of ExxonMobil Pipeline Company; 3301 C Street, Suite 400, Anchorage, AK 99503; telephone 832-868-2270.

APPLICANT'S POINT OF CONTACT: Mr. Brien Reep, Environmental and Regulatory Manager, ExxonMobil Development Company, Point Thomson Project, Post Office Box 190267, Anchorage, AK 99519-0267, telephone 907-564-3617.

LOCATION: Alaska's Beaufort Sea coastline, North Slope Borough, approximately 60 miles east of Prudhoe Bay and 60 miles west of Kaktovik, Alaska. The development would consist of 3 coastal gravel pads:

1. The Central Pad would be located at approximate Latitude 70.1713° N., Longitude 146.2568° W. in Sec. 34, T. 10 N., R. 23 E. and Sec.03, T. 09 N., R. 23 E., Umiat Meridian.

2. The East Pad would be located at approximate Latitude 70.1467° N., Longitude 146.1084° W., in Sec. 8, T. 09 N., R. 24 E., Umiat Meridian.

3. The West Pad would be located at approximate Latitude 70.1806° N., Longitude 146.4394° W., in Sec. 36, T. 10 N., R. 22 E., Umiat Meridian.

4. A proposed export pipeline would extend west 22 miles from the Central Pad to connect with an existing common carrier pipeline to the Trans Alaska Pipeline System.

5. The airstrip, mine site, and support pad would be located approximately 2.5 miles south of the Central Pad.

Vicinity and smaller scale maps are attached. Tabs 15, 16, and 17 of the permit application provide additional information on the geographic coordinates and legal description of the other proposed facilities. These include gravel fill roads, gravel pads, airstrip, mine site, elevated pipelines, processing facilities, and supporting infrastructure.

APPLICANT'S PURPOSE: Initiate commercial hydrocarbon production (natural gas condensate) and delineate and evaluate hydrocarbon resources in the Point Thomson area.

PROPOSED WORK: Total acreage of wetland fill would be approximately 267.5 acres. Fill would include gravel for drilling/production pads and connecting roads, airstrip, gravel mine and overburden replacement, vertical support members (VSM's) for in-field pipelines and an export pipeline, and pilings for a proposed barge offloading facility and service pier. Fill material would come from a new mine site located at approximately 2.5 miles inland at approximate Latitude 70.146.65° N. and Longitude 146.2528° W. Minor dredging and screeding in marine waters will be required in the barge docking area offshore of the Sealift Bulkhead and Service Pier with a small amount of fill placed onshore.

The project comprises the two major components of production facilities and an export pipeline. These include three gravel pads, 5 development wells, infield gathering lines, 12 miles of infield gravel roads, a 5,600 foot airstrip, a gravel mine, and processing facilities and support infrastructure. Two of the wells were drilled from the existing Central Pad in 2009-2010 under State and local approval and did not require new fill or additional DA authorization.

The use of Long Reach Direction Drilling (LRDD) allows development of the primarily offshore Thomson Sand Reservoir from three onshore pads located near the coast. The Central Pad (total 56 acres including 13.2 acres of existing fill) involves the expansion of an existing pad (Point Thomson Unit No. 3) to accommodate additional drilling, processing facilities, and support infrastructure (e.g. camps, utilities, warehouses, storage, and waste management facilities). At the Central Pad, processing facilities will separate hydrocarbon liquids from the natural gas, re-inject residual gas, and stabilize the liquid hydrocarbons for transport in the Point Thomson Export Pipeline.

The West and East Pads are strategically located to access the western and eastern extents of the Thomson Sand Reservoir. The West Pad (approximately 19 acres) would be a new pad to support drilling and production. It would be located 4 miles west of the Central Pad at 20+ feet elevation. The East Pad would include a new 11-acre pad on the sea coast at 17+ feet elevation connected to the existing 4.6 acre North Staines River No. 1 exploration pad, which will be utilized for temporarily staging equipment and camps during drilling. Gathering pipelines would be elevated a minimum of 7 feet above the wetland tundra surface on VSMs to transport hydrocarbons produced from the West and East Pads to the Central Processing Facility at the Central Pad.

Other proposed production infrastructure includes:

- A 5,600-foot gravel airstrip for all-season transportation;
- An onshore bulkhead and offshore mooring dolphins for offloading facility modules from sealift barges;
- A service pier and mooring dolphins for offloading smaller coastal re-supply barges;
- A boat launch to support access by emergency response vessels;
- An infield gravel road network (approximately 12 miles) for transport of personnel, equipment (including drilling rigs), materials and supplies between the three Pads and other field locations in support of drilling, operations and emergency response;
- A gravel mine site; and
- A Class I injection well (already permitted) for disposal of produced water, domestic wastewater and other authorized waste streams.

Construction activities are proposed to commence in the winter of 2012/13 and be completed by the winter of 2015/2016. Civil construction, including gravel placement and gravel mining, would be mainly conducted during the winters of 2012/13 and 2013/14. Production infrastructure construction would commence in early 2013 and be completed in winter 2015/2016. Sealift of large processing facility modules would take place in the summer of 2015. Drilling operations are planned to commence in early 2015 and be completed in early 2017. Facility module installation, commissioning, and startup are planned in 2015 to early 2016 followed by production and construction demobilization in 2016.

The export pipeline would be a common carrier pipeline and therefore subject to additional regulation (Federal Energy Regulatory Commission) from the infield gathering pipelines. The 22-mile long, 12-inch nominal diameter export pipeline would receive processed liquid hydrocarbons from the Central Processing Facility to a connection with the British Petroleum’s Badami Facility, Sales Oil Pipeline. The export pipeline would also be elevated a minimum of 7 feet above the wetland tundra surface on VSMs. Other export pipeline facilities would include a small dill pad at Badami for a leak detection and metering skid and a small pipeline crossing pad to allow ice road crossings. The export pipeline construction would be conducted from ice roads over two winter seasons in 2012/13 and 2013/14.

ADDITIONAL INFORMATION: Additional information is available from the Environmental Impact Statement (EIS) website established by the USACE for this proposal at www.pointthomsonprojecteis.com, or by contacting the USACE Project Manager above.

More information is also contained in the complete DA permit application, including a more detailed description of proposed facilities, additional technical plans and figures, and proposed mitigation. The complete application is available at the above cited website and published in the Draft EIS under the file number POA-2001-1082-M1, Beaufort Sea.

In addition, the Applicant has provided the USACE with supporting documentation to supplement its permit application. This documentation includes:

1. Point Thomson Project, Project Description (October 2009), as updated by the Point Thomson Project Addendum (September 13, 2010) and Point Thomson Project Update (February 11, 2011).

2. Point Thomson Project Environmental Report (November 2009) provides Applicant's analysis of relevant environmental impacts of the Project.

3. Point Thomson Project Export Pipeline Right-of-Way Lease Application (August 4, 2010).

4. Point Thomson Project Environmental Mitigation Report (June 17, 2011).

5. Point Thomson Project Section 404(b) (1) Practicability Analysis of Point Thomson Project Preliminary Draft Environmental Impact Statement Alternatives (May 13, 2011).

6. The Point Thomson Oil Spill Preparedness Report (June 17, 2011).

7. Applicant has also supported the National Environmental Policy Act and USACE Regulatory Program processes with submissions of technical information, responses to requests for information, and workshops, including a Hydrology Workshop (March 8, 2011), and a Gravel Mining and Rehabilitation Plan Workshop (March 15, 2011).

APPLICANT PROPOSED MITIGATION: The Applicant has proposed mitigation measures to avoid and minimize impacts to waters of the US from activities involving discharge of dredged or fill material in the Point Thomson Environmental Mitigation Report (June 17, 2011). The major avoidance, minimization, and compensatory mitigation measures are outlined below.

a. Avoidance: Avoid the use of significant offshore development structures and facilities to minimize impacts in the Beaufort Sea. The three pad configuration on the coast provides the optimal location for development of the predominantly offshore reservoir using LRDD and is intended to avoid the need for additional drilling pads to accommodate any potential future full field development.

b. Minimization: Project design, supported by wetlands, hydrology, and other studies, has been focused on minimizing environmental impacts. This includes minimizing the total area of wetlands fill and construction in marine/navigable waters. Examples include:

1. Remote project development without proposed permanent gravel road construction to the Prudhoe Bay infrastructure by reliance on seasonal ice roads, a gravel airstrip, and barging with minimal offloading facilities.

2. Use of three existing gravel pads, minimizing the need for new overall tundra wetland fill footprint by more than 20 acres.

3. Minimizing gravel pad size through optimization of facility and equipment layout.

4. Designing and locating pads, roads, bridges, and culverts to maintain natural drainage patterns and stream flows to the extent practicable.

5. Routing the infield gravel roads to minimize overall length and fill footprint, with consideration for hydrology impacts and wetlands values.

6. Limiting permanent structures in marine waters to vertical piles for the service pier, mooring dolphins, sealift barge ramp, and small boat launching ramp.

c. Compensatory Mitigation: Payment of an in-lieu fee to The Conservation Fund (TCF). TCF is the only in-lieu fee sponsor currently authorized to provide compensatory mitigation for impacts to waters of the US on Alaska's North Slope. The Applicant would work with TCF and the USACE to develop an appropriate Mitigation Plan to satisfy compensatory mitigation requirements. This would include opportunities which may be available on the North Slope.

WATER QUALITY CERTIFICATION: A permit for the described work will not be issued until a certification or waiver of certification, as required under Section 401 of the Clean Water Act (Public Law 95-217), has been received from the Alaska Department of Environmental Conservation.

CULTURAL RESOURCES: Section 106 of the National Historic Preservation Act and its implementing regulations (36 CFR 800) require Federal agencies to consider the effects of their undertakings on cultural resources that are eligible for the National Register of Historic Places. Consultation with the State Historic Preservation Officer (SHPO), tribes and other parties regarding plans to avoid, minimize, or mitigate any impacts to eligible cultural resources occurs throughout the Section 106 process. Issuance of a Federal permit qualifies as an "undertaking" under Section 106; therefore the impacts of the proposal on historical, cultural, and archaeological resources are being addressed in the EIS and will be considered in the decision whether to issue a permit. The USACE, as Lead Federal Agency for the Point Thomson Project EIS, has initiated consultation with the SHPO.

The Applicant has prepared and submitted a Cultural Resource Management Plan (CRMP), including a data gap analysis and fieldwork, to identify cultural resources in the project area. The CRMP was reviewed by North Slope Borough (NSB), Inupiat History, Language, and Culture (IHLC) Division and the Alaska Office of History and Archaeology (OHA) during its preparation. There are potentially eligible properties in the project area and a determination of effect will be made in consultation with the SHPO. Review of the applicant's CRMP and review of the Alaska Heritage Resources Survey (AHRS) constitutes the extent of cultural resource investigations by the USACE at this time. Any comments the SHPO or other

consulting parties may have concerning presently unknown archeological or historic data that may be lost or destroyed by work under the requested permit will be considered in our final assessment of the described work.

ENDANGERED SPECIES: The project area is within the known range of the Spectacled eider (Somateria fischeri) and Polar bear (Ursus maritimus). The project area is also within the historical range of Steller's eider (Polystic stelleri). All three species are listed as threatened under the Endangered Species Act (ESA) of 1973. One other species that may occur near the Project, the Yellow-billed Loon (Gavia adamsii), is a candidate for listing under the ESA.

The project area is also within the range of the Bowhead whale (Balaena mysticetus), Ringed seal (Phoca hisipida), and Bearded seal (Erignathus barbatus). Bowhead whales are listed as endangered, while Ringed and Bearded seals have been proposed for listing by NMFS as threatened under the ESA.

The Applicant has been designated by the USACE as the non-federal representative to prepare Biological Assessments (BAs) for the listed species, subject to review and approval by the USACE, to support the ESA Section 7 consultation process. Two BAs have been drafted for approval by the USACE for consultation with the USFWS and NMFS respectively:

- Point Thomson Project Biological Assessment of the Polar bear (Ursus maritimus), Spectacled eider (Somateria fischeri), Steller's eider (Polysticta stelleri), and Yellow-Billed loon (Gavia adamsii) - October 2011

- Biological Assessment of the Bowhead whale (Balaena mysticetus), Ringed seal (Phoca hispada), and Bearded seal (Erignathus barbatus) - October 2011

These draft BAs provide data on the distribution, abundance and habitat use of the listed and candidate species, and describe the effects of the project and proposed mitigation to minimize impacts on those species.

For species under the jurisdiction of US Fish and Wildlife Service, it has been preliminarily determined the proposal is "not likely to adversely affect" the Polar bear, Spectacled eider, and the Yellow-billed loon. The preliminary determination for the Steller's eider is "not likely to affect". It has also been preliminarily determined the activity "may affect, but is not likely to cause destruction or adverse modification" of designated Polar bear critical habitat.

Preliminarily, a determination of "not likely to adversely affect" the Bowhead whale, Ringed seal, and Bearded seal has been made in the draft BA for the National Marine Fisheries Service.

This application is being coordinated with the USFWS and the NMFS. Any comments they may have concerning endangered or threatened wildlife or plants or their critical habitat will be considered in our final assessment of the described work.

ESSENTIAL FISH HABITAT: The Magnuson-Stevens Fishery Conservation and Management Act, as amended by the Sustainable Fisheries Act of 1996, requires all Federal agencies to consult with the NMFS on all actions, or proposed actions, permitted, funded, or undertaken by the agency, that may adversely affect Essential Fish Habitat (EFH).

A review of fish species and studies in the Point Thomson Project area and a preliminary determination with respect to potential Project impacts on fish and EFH is included in the Point Thomson Project Draft EIS (DEIS).

TRIBAL CONSULTATION: The Alaska District fully supports tribal self-governance and government-to-government relations between federally recognized Tribes and the Federal government. Tribes with protected rights or resources that could be significantly affected by the proposed Federal action (e.g., a permit decision) have the right to consult with the Alaska District on a government-to-government basis. Views of each Tribe regarding protected rights and resources will be accorded due consideration in this process. This Public Notice serves as notification to the Tribes within the area potentially affected by the proposed work and invites their participation in the Federal decision-making process regarding the protected Tribal right or resource. Consultation may be initiated by the affected Tribe upon written request to the District Commander during the public comment period.

PUBLIC HEARING: Any person may request, in writing, within the comment period specified in this notice, that a public hearing be held to consider this application. Requests for public hearings shall state, with particularity, reasons for holding a public hearing. The USACE has public meetings to receive comments on the Point Thomson Project Draft EIS Barrow, Nuiqsut, Kaktovik, Fairbanks, and Anchorage, beginning on 05 December in Barrow.

EVALUATION: The decision whether to issue a permit will be based on an evaluation of the probable impacts, including cumulative impacts, of the proposed activity and its intended use on the public interest. Evaluation of the probable impacts, which the proposed activity may have on the public interest, requires a careful weighing of all the factors that become relevant in each particular case. The benefits, which reasonably may be expected to accrue from the proposal, must be balanced against its reasonably foreseeable detriments. The outcome of the general balancing process would determine whether to authorize a proposal, and if so, the conditions under which it will be allowed to occur. The decision should reflect the national concern for both protection and utilization of important resources. All factors, which may be relevant to the proposal, must be considered including the cumulative effects thereof. Among those are conservation, economics, aesthetics, general environmental concerns, wetlands, cultural values, fish and wildlife values, flood hazards, floodplain values, land use, navigation, shore erosion and accretion, recreation, water supply and conservation, water quality, energy needs, safety, food and fiber production, mineral needs, considerations of property ownership, and, in general, the needs and welfare of the people. For activities involving Clean Water Act Section 404 discharges (dredged and fill materials), a permit will be denied if the discharge that would be authorized by such permit would not comply with the Environmental Protection Agency's 404(b) (l) Guidelines. Subject to the preceding sentence and any other applicable guidelines or criteria (see USACE regulations at 33 CFR Parts 320.2 and 320.3), a permit will be granted unless the District Commander determines that it would be contrary to the public interest.

The USACE is soliciting comments from the public; Federal, State, and local agencies and officials; Alaska Native Tribes; and other interested parties in order to consider and evaluate the impacts of this proposed activity. Any comments received will be considered by the USACE to determine whether to issue, modify, condition or deny a permit for this proposal. To make this decision, comments are

used to assess impacts on endangered species, historic properties, water quality, general environmental affects, and other public interest factors listed above. Comments are used in the preparation of the Environmental Impact Statement for the proposal pursuant to the National Environmental Policy Act. Comments will also be used to determine the overall public interest of the proposed activity.

The USACE has determined the proposal may have significant impacts to the quality of the human environment and required an EIS be prepared. A Notice of Intent to Prepare an EIS was published in the Federal Register on December 4, 2009. The EIS process is ongoing and the public notice for this application is being published concurrently with the Point Thomson Project Draft EIS.

AUTHORITY: This permit will be issued or denied under the following authority:

(X) Perform work in or affecting navigable waters of the United States – Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. 403).

(X) Discharge dredged or fill material into waters of the United States – Section 404 Clean Water Act (33 U.S.C. 1344). Therefore, our public interest review will consider the guidelines set forth under Section 404 (b) of the Clean Water Act (40 CFR 230) and Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. 403).

Project drawings and Notice of Application for State Water Quality Certification are enclosed with this Public Notice.

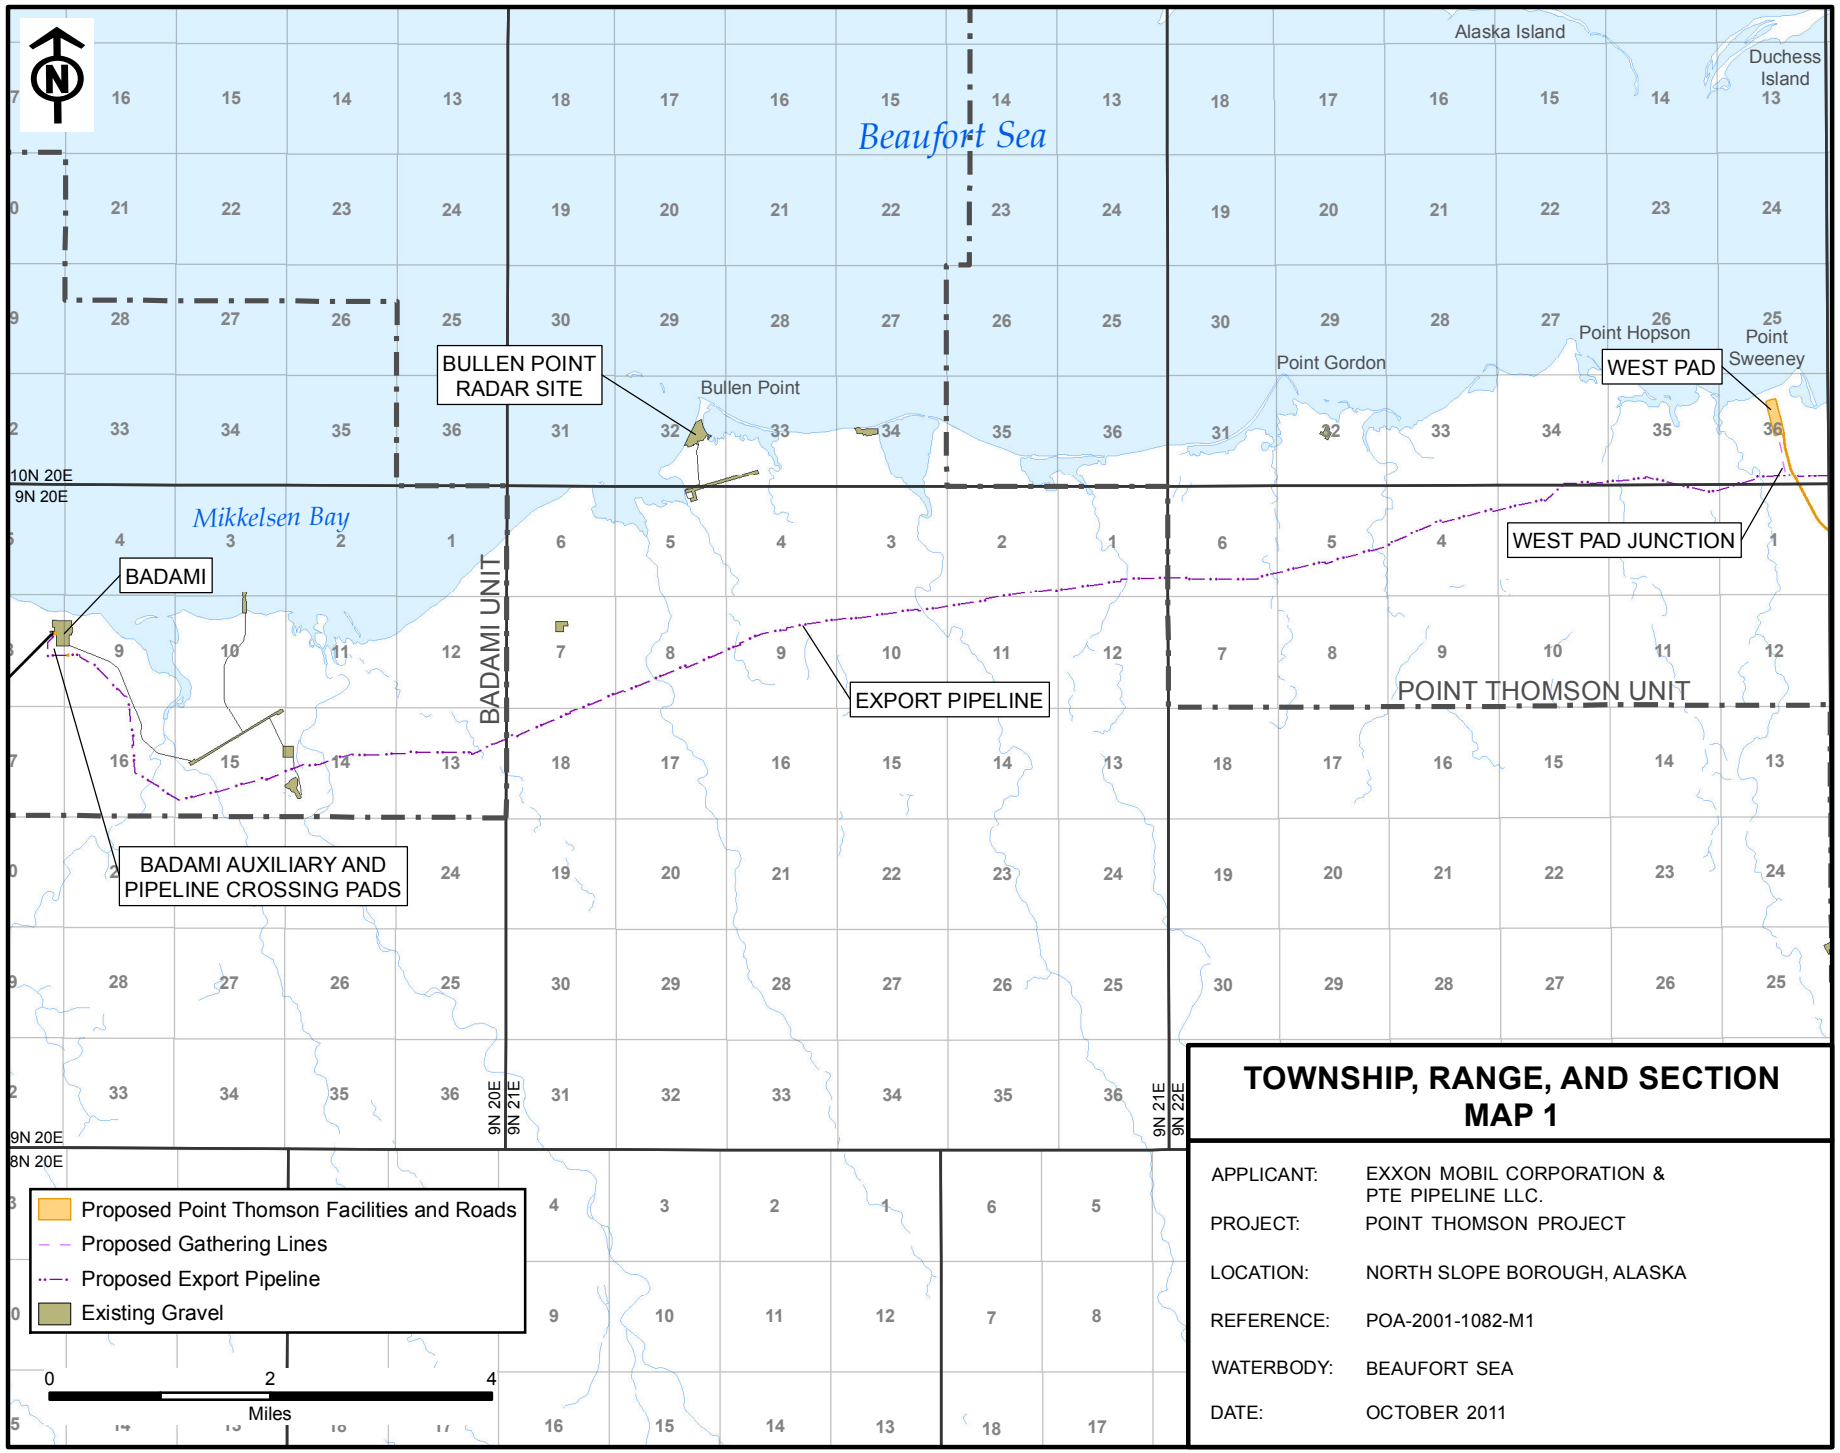
NOTICE OF APPLICATION FOR STATE WATER QUALITY CERTIFICATION

Any applicant for a federal license or permit to conduct an activity that might result in a discharge into navigable waters, in accordance with Section 401 of the Clean Water Act of 1977 (PL95-217), also must apply for and obtain certification from the Alaska Department of Environmental Conservation that the discharge will comply with the Clean Water Act, the Alaska Water Quality Standards, and other applicable State laws. By agreement between the U.S. Army Corps of Engineers and the Department of Environmental Conservation, application for a Department of the Army permit to discharge dredged or fill material into navigable waters under Section 404 of the Clean Water Act also may serve as application for State Water Quality Certification.

Notice is hereby given that the application for a Department of the Army Permit described in the Corps of Engineers' Public Notice No. **POA-2001-1082-M1, Beaufort Sea**, serves as application for State Water Quality Certification from the Department of Environmental Conservation.



After reviewing the application, the Department may certify there is reasonable assurance the activity, and any discharge that might result, will comply with the Clean Water Act, the Alaska Water Quality Standards, and other applicable State laws. The Department also may deny or waive certification.

Any person desiring to comment on the project, with respect to Water Quality Certification, may submit written comments to the address above by the expiration date of the Corps of Engineer's Public Notice.

Re: Final Application for Department of the Army, Clean Water Act Sec. 404 and Rivers and Harbors Act Sec. 10 Permit – Point Thomson Project

Dear Mr. Baij:

ExxonMobil Development Company (EMDC) is pleased to submit to the U.S. Army Corps of Engineers (USACE) a final Clean Water Act Section 404 and Rivers and Harbors Act Section 10 permit application for the Point Thomson Project (Project). We are also pleased to provide the attached Preliminary Jurisdictional Determination (PJD) for the Project.

The final permit application incorporates revisions suggested by your office on a draft application submitted for USACE review on August 19, 2011. We greatly appreciate your efforts to review the draft application to assure that it meets USACE requirements in conformance with 33 CFR Parts 320-332.

As previously discussed, and explained in the application, EMDC is submitting the application as the authorized agent for Exxon Mobil Corporation and PTE Pipeline LLC. This is specifically authorized by USACE regulations at 33 CFR 325.1(d)(8).

The application and referenced documents provide information on the scope and nature of the Project for interested parties and the public. This includes the USACE as lead agency, cooperating agencies, other interested State and federal agencies, the North Slope Borough, and the neighboring communities of Kaktovik and Nuiqsut. We request that the USACE make the full application available on the Point Thomson Project EIS website so that interested members of the public may review the full document and attachments.

EMDC is providing the application submittal now to allow sufficient time for the USACE to initiate the Public Notice and public review of the application in coordination with the publication of the Draft Environmental Impact Statement for the Project.

As you know, EMDC has engaged in a comprehensive pre-application process starting with several meetings with the USACE and EPA beginning in March 2009. A pre-application draft permit application and Project Description were submitted to the

USACE in July 2009, which led to a determination by the USACE in the same month that an EIS would be necessary. A multi-agency pre-application meeting was held in August 2009, and subsequent meetings were held with individual agencies. A formal draft application was submitted to the USACE on October 19, 2009 to initiate agency review of the Project, including the federal review process under the National Environmental Policy Act.

Since the EMDC October 2009 submittal and the December 4, 2009 USACE Notice of Intent to prepare an EIS, EMDC has supported the EIS and Section 404/10 permitting processes by participating in scoping meetings, providing technical reports, responding to Requests for Information (RFI's), and participating in agency workshops and the inter-agency EIS Coordination Team meetings.

In submitting this application, EMDC also relies upon a number of technical documents and relevant information in Project permit applications provided to the EIS process during the timeframe of this Section 404/10 application. As we discussed, in the interests of brevity and document administration, we are limiting the attachments to this application. However, these documents, including the ones listed below, provide additional documentation and support for this permit application and are incorporated by reference. We request that these be included in the record for the permit application.

Documents Incorporated by Reference:

1. Point Thomson Project Export Pipeline Right-of-Way Application submitted to ADNR, SPCO (8/4/2010)

2. ExxonMobil's Section 404(b)(1) Practicability Analysis of Point Thomson Project Preliminary Draft Environmental Impact Statement Alternatives (May 13, 2011)

3. Technical Brief #1 – Well Pad Locations (June 25, 2010)

4. Oil Spill Preparedness (June 17, 2011)

As noted above, submitted with the permit application is EMDC's PJD for the Project. This is being provided to assist USACE in developing an approved Jurisdictional Determination. The attached PJD report prepared by OASIS Environmental, Inc. presents the results of wetland delineations and wetland and waters mapping for the purpose of identifying areas in the vicinity of the Project that are under the jurisdiction of Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act. Approximately 58,000 acres were evaluated for the PJD. The included acreage provides sufficient aerial coverage around the proposed project facilities to help the USACE understand the overall vegetation and wetland communities of the surrounding area, not just the relatively small areas directly impacted by the Project (267.5 acres).

The Department of the Army permit application and the introduction section to the PJD provides the USACE with detailed project location information, directions to the site and a detailed project description. The contact names for the PJD are the same as those for the application. Appendix A of the PDJ provides a series of maps that depict all the vegetation classes identified during the analysis. Accompanying tables provide acres of each vegetation type and the percent the vegetation type occupies within the complete mapped area.

If you have any questions, please contact me at (907) 564-3617 or via email (brien.e.reep@exxonmobil.com), or Steve Calder at (907) 564-3787 or via e-mail (steve.calder@exxonmobil.com).

Sincerely,

For and On Behalf of Exxon Mobil Corporation

POINT THOMSON PROJECT

ExxonMobil Development Company (EMDC), as agent on behalf respectively of Exxon Mobil Corporation (ExxonMobil) and of PTE Pipeline LLC, a wholly-owned subsidiary of ExxonMobil Pipeline Company, submits the following Application for a Department of Army (DA) Permit for the Point Thomson Project (Project) to the United States Army Corps of Engineers (USACE). This permit is requested to be issued pursuant to the Clean Water Act (CWA) Section 404 and the Rivers and Harbors Act Section 10. A draft Preliminary Jurisdictional Determination is being provided separately to USACE.

The Project comprises two major components: the Initial Production System (IPS), which includes development wells, infield gathering lines, processing facilities, and support infrastructure, and the Point Thomson Export Pipeline (PTEP). The IPS comprises facilities of the Point Thomson Unit (PTU). The PTEP is the common carrier pipeline used to transport hydrocarbon liquids from the Point Thomson area to, and interconnect with, the Badami Sales Oil Pipeline (BSOP), which connects to the Endicott Pipeline and the Trans Alaska Pipeline System (TAPS). Permit Number POA-2001-1082-M1, Beaufort Sea, has been assigned by USACE to the Project.

ExxonMobil is the operator and a working interest owner of the PTU. As operator, ExxonMobil is conducting operations on behalf of the PTU working interest owners for the IPS portion of the Project[1]. PTE Pipeline LLC, owns and will be the operator of the PTEP as a common-carrier pipeline which will be separately regulated under applicable law.

The two Project components are integral to, and necessary for, completion and operation of the Project. The Project as a whole is subject to a unified environmental review process pursuant to National Environmental Policy Act (NEPA) and USACE regulations. Both the IPS and PTEP will be constructed by EMDC acting under agreement with ExxonMobil and PTE Pipeline LLC. The respective companies have each designated EMDC as their agent for the purpose of submission of this application.

This application is consistent with USACE regulations at 33 Code of Federal Regulations (CFR) 325.1(d)(2) which provide that all activities which are reasonably related to the same project, and for which a DA permit would be required, should be included in the same permit application. The regulations at 325.1(d)(8) further provide that an application may include the activity of more than one owner provided the character of the activity of each owner is similar and in the same general area and each owner submits a statement designating the same agent. In addition, this application addresses USACE comments made in response to a draft application submitted to USACE in October 2009, and ongoing consultation with the USACE since that time.

[1] Other principal working interest owners of the Point Thomson Unit are BP Exploration (Alaska) Inc., Chevron U.S.A. Inc., and ConocoPhillips Alaska, Inc.

In addition, this application includes activities on existing gravel pads subject to USACE permits held by ExxonMobil listed below[2]:

- Pt. Thomson Disposal Site (permit no. 071-OYD-4-810264) (Exxon Company USA)
- Alaska State C-1 Pad (permit no. 071-OYD-4-800015) (Exxon Company USA)

In order to proceed on a unified basis with respect to DA permits for the IPS portion of the Project and the PTU, ExxonMobil requests that these permits be revised to be consistent with the planned IPS uses and relevant conditions, and incorporated in the final DA permit for the Project[3].

Organization of the Application

The application form is presented first, followed by signature pages, table of contents, and a list of acronyms and abbreviations. Several sections then follow providing information corresponding to the numbered tabs in the DA Application form. Following those sections is a set of figures. Lastly, there are two appendices:

A. Point Thomson Project Environmental Mitigation Report, June 17, 2011
B. Point Thomson Project Mining and Rehabilitation Plan, Point Thomson Gravel Mine Site (October 2011)

[2] The Pt. Thomson Disposal Site and Alaska State C-1 permits were previously issued to Exxon Company USA, a former operating division within Exxon Corporation, and are therefore held by Exxon Mobil Corporation.

[3] In addition, the North Staines River Well Pad No. 1 is subject to Corps permit no. 071-OYD-2-810203 issued to Phillips Petroleum Company. Phillips (now ConocoPhillips Alaska, Inc.) is a Point Thomson Unit working interest owner. As a Point Thomson Unit Operator, ExxonMobil has authority to undertake activities on the pad, and ExxonMobil will coordinate with ConocoPhillips as appropriate with respect to this permit. Further details on activities on existing pads are provided in Tab 18.

APPLICATION FOR DEPARTMENT OF THE ARMY PERMIT
(33 CFR 325)

OMB APPROVAL NO. 0710-0003
EXPIRES: 31 August 2012

Public reporting burden for this collection of information is estimated to average 11 hours per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Department of Defense, Washington Headquarters, Executive Services and Communications Directorate, Information Management Division and to the Office of Management and Budget, Paperwork Reduction Project (0710-0003). Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. Please DO NOT RETURN your form to either of those addresses. Completed applications must be submitted to the District Engineer having jurisdiction over the location of the proposed activity.

PRIVACY ACT STATEMENT

Authorities: Rivers and Harbors Act, Section 10, 33 USC 403; Clean Water Act, Section 404, 33 USC 1344; Marine Protection, Research, and Sanctuaries Act, Section 103, 33 USC 1413; Regulatory Programs of the Corps of Engineers; Final Rule 33 CFR 320-332. Principal Purpose: Information provided on this form will be used in evaluating the application for a permit. Routine Uses: This Information may be shared with the Department of Justice and other federal, state, and local government agencies, and the public and may be made available as part of a public notice as required by Federal law. Submission of requested information is voluntary, however, if information is not provided the permit application cannot be evaluated nor can a permit be issued. One set of original drawings or good reproducible copies which show the location and character of the proposed activity must be attached to this application (see sample drawings and instructions) and be submitted to the District Engineer having jurisdiction over the location of the proposed activity. An application that is not completed in full will be returned.

TAB 15: LOCATION OF PROPOSED IPS

TAB 16: OTHER LOCATION DESCRIPTIONS

TAB 17: DIRECTIONS TO SITE

The proposed Project is located at a remote site on the North Slope of Alaska, with the initial production system (IPS) Central Processing Facility (CPF) located approximately 50 miles east of Prudhoe Bay and approximately 22 miles east of Badami (Figure 1). The Point Thomson Export Pipeline (PTEP) extends about 22 miles from the CPF to a point of connection with the existing Badami Sales Oil Pipeline (BSOP) at the Badami Central Facilities Pad. Badami is located approximately 20 miles east of the Endicott Causeway. The Project is currently accessible by seasonal ice roads, coastal barging, tundra travel and helicopter.

The IPS location is further defined as being located on the eastern North Slope of Alaska on the mainland between Bullen Point and Brownlow Point. Flaxman Island and a chain of barrier islands, known as the Maguire Islands (including Challenge, Alaska, Duchess and North Star Islands), lie offshore of the proposed IPS development. The CPF will be located immediately south of Mary Sachs Entrance. The point of origin of the PTEP is the Point Thomson CPF. The point of termination of the PTEP is at the point of connection with the existing Badami Pipeline.

The Project location is determined by the need to access the Thomson Sand reservoir, which is predominantly an offshore, underwater reservoir (Figure 5). Figures 1-3 show the Project's major facilities' general vicinity and township, range, and section numbers; Table 1 lists their latitude and longitude (North American Datum 1983) and township, range, and section numbers; Figure 4 shows the IPS facilities layout including the proposed location of the gravel roads, gravel pads, gravel airstrip, gathering (flow) lines, and the related PTEP; Table 2 lists the legal description alignment of the construction and operational right-of-way (ROW) of the PTEP.

TAB 18: NATURE OF ACTIVITY

The Project comprises two major components: the IPS, which includes development wells, infield gathering lines, processing facilities, and support infrastructure, and the PTEP, which is the common carrier pipeline used to transport hydrocarbon liquids from Point Thomson to Badami. Hydrocarbon liquids will then be transported through the BSOP, the Endicott Pipeline, and the Trans Alaska Pipeline System (TAPS).

Initial Production System

The proposed IPS will initiate commercial hydrocarbon production from the Thomson Sand reservoir of the PTU. The Thomson Sand is a high-pressure gas condensate reservoir that underlies state lands onshore and state waters offshore. Oil may also be present in two distinct intervals: the Thomson Sand oil rim and the Brookian hydrocarbon sands. See Figure 5 for location of the Thomson Sand reservoir.

ExxonMobil, as PTU operator and working interest owner, proposes to produce gas from the Thomson Sand reservoir, recover liquid hydrocarbons, and re-inject the residual gas back into the Thomson Sand reservoir, with the injected gas available for future production. The Project will also delineate and test other hydrocarbon resources encountered, and obtain information about reservoir connectivity and the effectiveness of production of gas condensate that is essential in determining subsequent development plans. The IPS will help address the significant technical uncertainties associated with development of the reservoir and processing facilities. The Project will establish a design footprint that facilitates future full development of the reservoir and delineation of the hydrocarbon resources of the PTU with the least environmental impact practicable.

The IPS includes the necessary infrastructure to drill and produce five development wells from three pads (Central, East and West Pads). The first two wells at the Central Pad (PTU-15 and PTU-16) were drilled, cased, flow-tested, and suspended in 2009 and 2010. The CPF separates hydrocarbon liquids from the natural gas, re-injects the residual gas, and stabilizes the liquid hydrocarbons for transport. This is accomplished by four large facility modules for separation, compression, power generation and utilities.

The CPF is being designed with the capacity to process 200 million standard cubic feet per day of natural gas for recovery of approximately 10,000 barrels per day (bpd) of condensate. Condensate is the hydrocarbon liquid that condenses from the produced natural gas as pressure and temperature fall below original reservoir conditions during production and surface handling at processing facilities.

At the CPF, the three-phase stream (gas, water, and hydrocarbon liquids) produced from the wells will be separated and hydrocarbon liquids will be recovered and stabilized to meet pipeline tariff specifications from PTEP to the TAPS Pump Station 1. Produced water will be injected into a Class 1 disposal well. Produced gas will be compressed and re-injected into the Thomson Sand reservoir through the gas injection well at the required injection pressures of approximately 10,000 pounds per square inch gauge

(psig). Produced natural gas will be used as the primary fuel source for the facility. A connection to the gas injection well also allows use of natural gas as fuel when the production operation is shutdown, with diesel fuel used for an additional backup in case of an emergency.

In addition to the CPF, the Central Pad will also include the infrastructure to support remote drilling and production operations, such as: camps, offices, warehouses, and maintenance shops; electric power generating and distribution facilities; diesel fuel, water, and chemical storage; treatment systems for drinking water and wastewater; waste management facilities; and communications facilities. Project design factors that minimize the size of the Central Pad are described in Appendix A, Environmental Mitigation Report (EMR). In addition to accommodating drilling operations, both the East and West Pads will include areas required for production and metering facilities that accommodate full wellstream production to the CPF, as well as necessary supporting infrastructure. Smaller gravel pads, including the Alaska State C-1 Pad and the Water Access Pad, will support staging, storage and water supply operations.

The proposed configuration of the three production pads is necessary (and strategically located) to delineate the Thomson Sand reservoir and effectively access its offshore portions from onshore locations utilizing long-reach directional drilling (LRDD). The Central Pad is located to access the core of the reservoir; the East and West Pads are located to access the eastern and western extents, respectively (Figure 4). Gathering lines are planned to transport hydrocarbons produced from the East and West Pads to the CPF (Figures 33-38, 40-42). The proposed three-pad configuration, combined with LRDD technology, will allow the hydrocarbon resource to be evaluated and developed with minimal expansion required to meet reasonably foreseeable future field development scenarios (e.g., expanded gas cycling and/or gas sales). The locations of the Central and East Pads were also chosen to allow utilizing existing exploration well pads, which reduces new gravel footprints.

From the IPS, stabilized hydrocarbon liquids will be transported through the approximately 22-mile long PTEP to existing common carrier pipelines for delivery to the TAPS. The PTEP is further described in a later section.

Other infrastructure essential for Project site and infield access will include:

- A gravel airstrip for all-season transportation and emergency response (Figures 21-24).
- An onshore bulkhead and mooring dolphins for offloading sealift modules (Figures 11-13).
- A service pier and mooring dolphins for offloading smaller coastal barges (Figures 11-13).
- A boat launch to support access by emergency response vessels (Figures 15-16).
- An in-field gravel road network to provide a reliable and safe year-round means to transport personnel, equipment, and drilling rigs between the Central Pad and

field locations in support of operations, drilling, and emergency response activities. No gravel road between Point Thomson and other Alaska North Slope infrastructure is planned (Figures 43-60).

- Use of a former gravel mine (Alaska State C-1 pit) as a fresh water source (Figure 25-26).
- A new gravel mine to support construction, with the mined pit reclaimed as a freshwater habitat and backup water source (Figures 61-66).
- Single season winter ice roads and pads used for construction, operations and other activities, as needed.

Activities on Existing Permitted Pads

The IPS component of the Project includes proposed activities on three existing pads already subject to United States Army Corps of Engineers (USACE) permits.

The existing Central Pad is subject to Permit No. 071-OYD-4-810264 issued to Exxon Company USA on November 9, 1981, and modified on January 22, 1982. On November 20, 2008, USACE issued ExxonMobil a letter advising that use of the Central Pad for the Point Thomson drilling program did not require further USACE permitting. ExxonMobil subsequently drilled Wells PTU-15 and PTU-16 on the Central Pad in 2009-10. As set forth above, the Central Pad will be expanded in the Project to accommodate production facilities and additional drilling.

The existing C-1 Pad is subject to Permit No. 071-OYD-4-800015 issued to Exxon Company USA on April 9, 1980. The gravel pad was used to drill an exploratory well. The well was determined capable of producing in paying quantities by the State of Alaska in 1981. The underlying lease was subsequently included in the PTU in 1984. The effect of each of these actions was to extend the term of the lease[4]. The site also contains a reserve pit, which has been closed out with the approval of the Alaska Department of Environmental Conservation (ADEC). Including the existing pad in Project plans provides about four acres of valuable gravel pad space with virtually no additional wetlands impacts. Use of existing gravel pads is a key avoidance mitigation measure employed in the Project.

During Project construction, the C-1 Pad will be used for equipment lay down and storage space. The central location of the C-1 Pad, adjacent to the planned infield gravel road system, close to the airstrip and away from the active drilling and production pads, make it important and strategically located for construction, drilling and long-term operations. In addition to staging and storing equipment and supplies, it could also serve as a location for a seasonal camp or temporary shelter if there were an emergency on

[4] Alaska Statute (AS) 38.05.180(m) provides, "An oil and gas lease shall be automatically extended…if the lease is committed to a unit approved by the commissioner. A lease issued under this section covering land on which there is a well capable of producing oil or gas in paying quantities does not expire because the lessee fails to produce oil or gas unless the lessee is allowed reasonable time to place the well on a producing status."

one of the other pads. During the recent drilling program, the C-1 pad was a designated safe haven in the event of an emergency on the Central Pad and was used to store well control emergency response equipment. The C-1 Pad would also support reasonably foreseeable future development including production beyond the planned scope of the current Project.

Because of the expanded area of the Central Pad, and the continued use of these two pads for Unit operations, ExxonMobil requests that the existing permits, with any appropriate conditions, be incorporated into permit POA-2001-1082-M1. Because the permits were issued to Exxon Company USA, a former division of Exxon Mobil Corporation, they can be incorporated into a new ExxonMobil permit for the Project without need for any further legal formalities. ExxonMobil as permittee and Unit Operator will maintain responsibility for the permits and any conditions, as indeed it already does.

Incorporation of these two permits into the new permit will simplify administration of permit obligations for the Project. It also serves another very significant purpose. Under State law, the Point Thomson field and leases have been unitized to form the PTU. Unitization refers to the consolidation of leasehold interests in oil or gas covering a common source of supply so that the supply is explored, developed, and produced as a single unit without regard to separate ownerships. This serves the fundamental purpose of conservation—the maximization of hydrocarbon recovery and the minimization of costs and environmental impacts—by avoiding competing, piecemeal, and redundant development on separate leases[5]. Basic legal principles regarding unitization provide that activities performed on one of the leases are treated as being performed on all of the leases[6].

Incorporation of all Project activities into a single permit will ensure the permit addresses Project activities as a whole, not in terms of activity of individual pads, with permit conditions applicable to the field activities as a whole—in accordance with the fundamental purpose of unitization. This will also ensure consistency with State law, which provides for treatment of Unit obligations on this basis. This will avoid any conflict between federal and state permitting by acknowledging the unitized nature of the field

[5] As explained by a leading treatise, "The purpose of unitization is to permit the entire field … to be operated as a single entity, without regard to surface boundary lines. Both economics and property rights require the integration of a field in order for such operations as gas cycling, pressure maintenance, and secondary recovery to be conducted…" Williams and Meyers, *Oil and Gas Law*, Vol. 6, §901, pages 3-4 (1993).

[6] Federal law recognizes the same principles of unitization. For example, the IRS code at 26 U.S.C. § 614, "Definition of property," addressing rules for operating mineral interests in oil and gas wells, provides that "if one or more of the taxpayer's operating mineral interests participate, under a voluntary or compulsory unitization or pooling agreement, in a single cooperative or unit plan of operation, then … (i) **they shall be treated for all purposes of this subtitle as one property**…" *Id*. at 614(b) (3) (emphasis added). In another example, federal leasing regulations under the Outer Continental Shelf Lands Act are required to contain provisions "for unitization, pooling, and drilling agreements." 43 USC 1334(a) (4).

and the accompanying recognition that remediation or rehabilitation obligations under the permit will be addressed consistent with unitization of the field.

The existing North Staines River No.1 pad is subject to USACE permit no. 071-OYD-2-810203 issued to Phillips Petroleum Company. The proposed East Pad will be adjacent to the North Staines pad, which will be utilized for staging of equipment and camps during drilling. The North Staines pad will not be expanded in size although a small amount of gravel may be placed on it to level it and to provide a ramp for travel between the East Pad and North Staines pad. As PTU Operator, ExxonMobil has authority to undertake proposed activities on the North Staines pad, and ExxonMobil will coordinate with ConocoPhillips with respect to the proposed use of this pad and permit.

Point Thomson Export Pipeline

The PTEP will transport liquid hydrocarbons processed at the CPF to existing common carrier pipelines for delivery to TAPS. The PTEP will be owned and operated by PTE Pipeline LLC[7], under terms of an ROW lease issued by the Alaska Department of Natural Resources (ADNR) State Pipeline Coordinator's Office (SPCO) under Alaska Statute (AS) 38.35. The PTEP ROW Lease approval process addresses pipeline design basis, route, directly associated facilities and environmental considerations. The information that follows provides a general overview of the PTEP. The Figures in this application include updates to the PTEP since the ROW lease application was submitted on 4 August, 2010.

The ROW operational footprint will be a 100-foot corridor along the pipeline. The temporary construction ROW will be a nominally 400 foot wide corridor along the pipeline. The PTEP will be constructed using typical winter North Slope construction practices, utilizing ice roads and pads. Additional temporary storage and staging lay down areas on seasonal ice pads will be required to support pipeline construction. However, space on existing or new gravel pads at the Point Thomson Central Pad or the Badami Central Facilities Pad may be used for temporary storage along with existing staging and storage pads in Deadhorse.

The pipeline will be made of carbon steel (API 5L-X65) with a nominal 12-inch diameter (12.75-inch actual outside diameter) and be covered with 3 inches of insulation to yield an overall outside diameter of 18.75 inches. The pipeline will have a maximum allowable operating pressure of approximately 2,035 pounds per square inch gage. The minimum mainline pipeline wall thickness will be 0.406 inches, which includes a corrosion allowance of 0.125 inches. The pipeline will have an initial throughput of approximately 10,000 bpd. However, the pipeline has the capacity to handle a larger throughput commensurate with full field development. The PTEP wall will be thickened, where

[7] PTEP ownership begins between the custody transfer meter skid and pig launcher in Module 103 (at the IPS Central Processing Facility), at the transition from carbon steel to low temperature carbon steel and includes all facilities downstream of this point to the connection point at the Badami Sales Oil Pipeline.

necessary, based generally on proximity to the coast, to prevent leaks in the event of accidental bullet strikes from coastal hunters. An external coating of fusion-bonded epoxy (FBE) and polyurethane foam insulation, with a bonderized sheet metal outer jacket, will be employed on the PTEP to coincide with best available North Slope practices. Figures 31-34 show an overview of the pipeline. Figures 36-39 show cross sections of the export pipeline; and Figures 40-42 show typical export pipeline road crossings.

The proposed PTEP will be supported on Vertical Support Members (VSMs) with "Z-type" offsets/expansion loops to permit extension and shortening of the pipeline due to thermal effects. The VSMs will be designed and installed to provide at least 7 feet of clearance between the lowest point of any element being supported by VSMs (e.g., pipe insulation, including pipeline attachments such as tuned vibration absorbers, electrical communication cables, etc.) and the ground surface. Between the CPF and the junction to the West Pad, VSMs are designed to carry both an 8-inch nominal diameter gathering line and the PTEP (Figure 38). Since microwave communication will be used between Point Thomson and Badami, there will not be power/communications cables extending to Badami.

The configurations of pipelines on each VSM along with the site-specific geotechnical conditions govern the diameter, wall thickness and depth of embedment of the VSMs into the ground. Survey crews mark the VSM's location on the ground; drilling crews drill holes to the designed depth with either air drills or regular auger drills. After placement of the VSM into the hole, a slurry mix of sand, aggregate, and water is poured from a mixer truck into the annulus around the VSM and vibrated to remove any air pockets. The slurry then freezes and holds the VSMs in place to support the pipeline(s). Spoils are collected from the snow surface and will be transported to the Point Thomson gravel mine, combined with overburden, and placed in the gravel mine as part of the reclamation plan or disposed in other approved locations.

The PTEP will connect to BSOP through a piggable wye, which allows each pipeline to be internally inspected by means of pigging. A leak detection metering skid will be installed on a new small gravel pad (estimated to be less than 0.3 acres) near the existing Badami flare access road. Additionally, a 40 foot x 40 foot gravel pad (PTEP pipeline crossing pad) will be constructed with a cased pipeline crossing (Figures 29-30) providing structural protection to the pipeline. The pad will be located approximately 450 feet south of the existing Badami pad to facilitate the Badami Unit's ongoing development.

TAB 19: PROJECT PURPOSE AND NEED

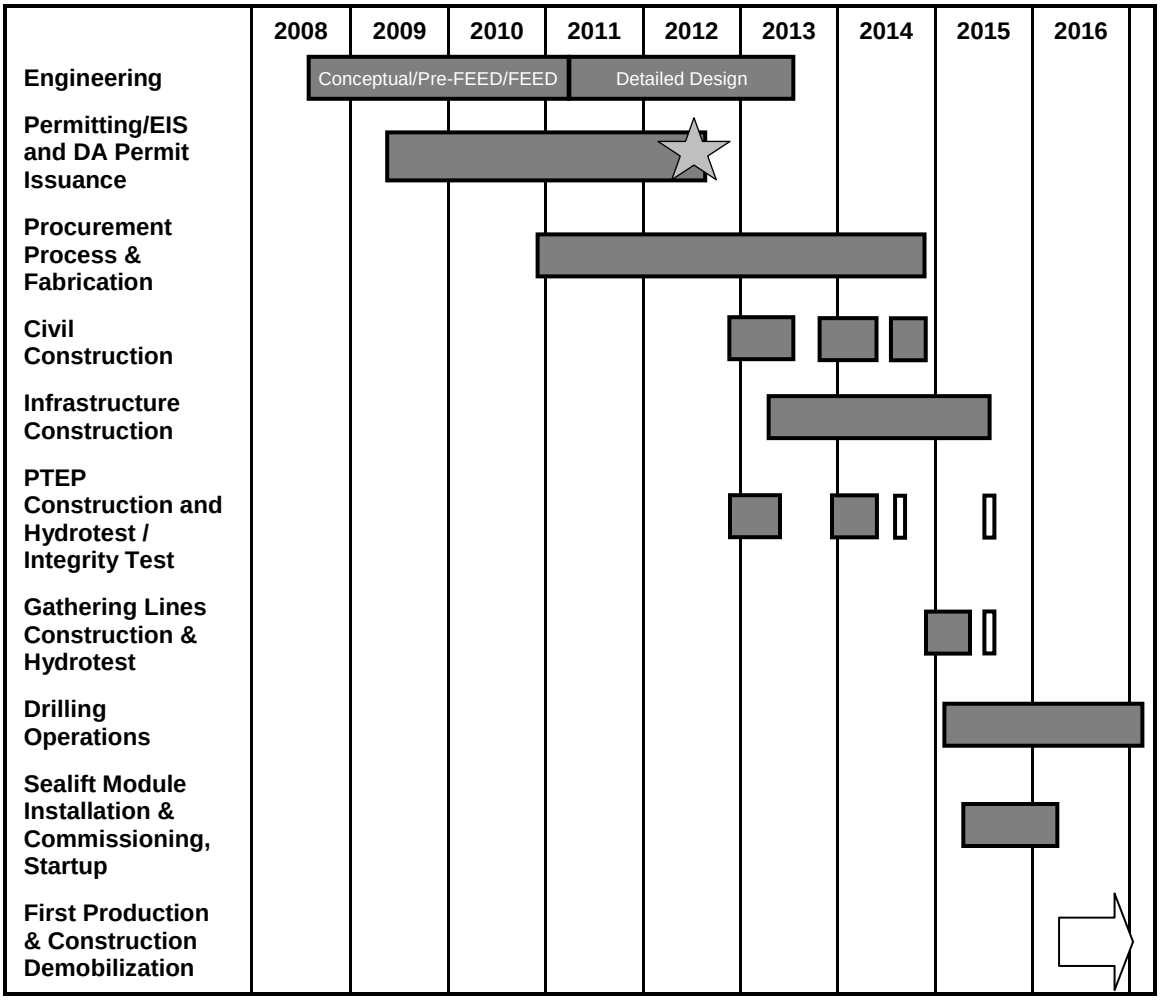
The Project will initiate commercial hydrocarbon production of the Thomson Sand reservoir by the winter season of 2015-16. The Project will deliver liquid hydrocarbons to TAPS Pump Station No. 1 at Prudhoe Bay for shipment to market. Initial production of liquid hydrocarbons is expected to be approximately 10,000 bpd. The Project will delineate and evaluate hydrocarbon resources in the PTU.

ExxonMobil as PTU operator and the PTU owners have committed to the production of liquid hydrocarbons from the Thomson Sand by winter season 2015-16. ADNR has recognized this commitment and has authorized production consistent with this schedule. The State's position is that production is required at the earliest feasible time. The proposed Project will achieve this important purpose.

Production of liquid hydrocarbons at Point Thomson serves other public purposes and needs. Development of this resource will help the U.S. meet domestic energy demand and reduce dependence on foreign sources of oil. Production at Point Thomson will help offset declining production from Alaska's North Slope reservoirs, and will help maintain the throughput of TAPS.

The Project will provide economic benefits to the state, North Slope Borough (NSB), and local communities through the creation of new jobs and tax revenues. The Project will provide an important source of employment for Alaska businesses, workers, and local residents. This will include both temporary jobs during drilling, engineering, procurement, and construction, and long-term jobs supporting permanent operations. The Project will be a source of new revenue for the State of Alaska and the NSB, helping to offset declining revenue from existing hydrocarbon production and facilities.

ExxonMobil believes the Project represents the best plan for field development, considering geological, resource, commercial, and legal uncertainties. A principal goal of the Project is to establish a design footprint that facilitates future full development of the reservoir and delineation of the hydrocarbon resources of the PTU with the least environmental impact practicable. The Project's design and flexibility accommodates foreseeable options for production by winter season 2015-16 and beyond.



The Project features a three-pad configuration, the optimal development design for resource recovery, delineation and conservation, and encompasses the smallest footprint necessary for these purposes. The configuration of the Project is designed to delineate and produce reservoir resources by using LRDD techniques from onshore pads. While more direct access to the reservoir would be provided by offshore platforms, the approach chosen minimizes impacts in marine waters. The CPF is located on an expanded existing Central Pad, incorporating the recently drilled PTU-15 and PTU-16 wells.

Development of the PTU resources beyond winter season 2015-16 is dependent upon many factors that cannot be determined at present. Point Thomson is the largest discovered, undeveloped natural gas field in Alaska. No pipeline exists to bring Alaska

North Slope natural gas to market, and there is substantial uncertainty about whether or when such a pipeline may be constructed. Nevertheless, Point Thomson natural gas reserves are essential to the development of a gas pipeline. Should such a pipeline be built, natural gas from Point Thomson would be an important energy source for the U.S. and Alaska. Development of the Project can be expected to facilitate potential construction of a natural gas pipeline by providing an infrastructure footprint for potential future production of gas. However, gas production and delivery into a pipeline is not part of the Project.

Schedule

Estimated timeframes for major Project components are shown in the diagram below. This schedule assumes presently anticipated dates for receipt of permits and other regulatory approvals. While initiating production in winter 2015-16 is essential to achieving the Project purpose, the actual timing of some Project components may vary to accommodate execution plan contingencies.

FEED = front-end engineering design
EIS = Environmental Impact Statement

TAB 20: REASONS FOR DISCHARGE

North Slope Wetlands

Wetlands subject to regulation under Section 404 of the Clean Water Act (CWA) comprise the vast majority of the North Slope, including the Project area. Project area wetlands are regulated as Waters of the United States under the Clean Water Act and subject to permits administered by USACE under Section 404. The marine components of the Project, as summarized below, are also regulated by the USACE under Section 10 of the Rivers and Harbors Act.

Alaska's North Slope is underlain by continuous permafrost; this perennially frozen ground creates a near-surface confining layer, leading to the ubiquitous wetlands characteristic of the Arctic Coastal Plain (ACP). The near continuous wetland characteristics associated with the North Slope is further indicated by the results of numerous Project-specific wetland inventories and the National Wetland Inventory Maps. Both sources show that wetlands are continuous throughout the North Slope and specifically within the proposed Project area.

Proven Arctic engineering practices evolved through 40 years of oil and gas exploration and development on the North Slope have demonstrated that placement of gravel fill is necessary to preserve the thermal integrity of the permafrost, and to provide stable roads, working surfaces, and foundations for the installation of facilities. At the same time, technology and best management practices on the North Slope have evolved to avoid or minimize impacts of fill placement, specifically Project footprints and related impacts. Such measures are detailed in the attached *Environmental Mitigation Report* (Appendix A) and the *Mitigation Statement* provided in (Tab 23).

There are no practicable, non-wetland alternatives to the proposed Project, i.e., there are no upland alternatives that could be used to develop Point Thomson hydrocarbon resources. The nearest extensive upland areas (i.e., areas with limited jurisdictional wetlands) are in the northern foothills of the Brooks Range, approximately 20 miles south of the Project. This distance is far beyond the technological capabilities of directional drilling or practicable placement of non-drilling facilities.

The majority of the Thomson Sand reservoir lies offshore. Due to the areal extent of the reservoir and the inability to reach all bottom hole targets from a single drilling location, the IPS features a configuration of three drilling/production pads for optimum development design for resource recovery, delineation, and conservation, while disturbing the smallest footprint needed for these purposes. This configuration is designed to delineate and produce reservoir resources by utilizing LRDD techniques from onshore pads, which minimizes impacts to the marine environment. All three pads are necessary to delineate and develop the Thomson Sand Reservoir, for production testing, and to evaluate Unit hydrocarbon resources.

Project Components and Facilities

The number and location of facilities have been designed to incorporate requirements for safety, construction, operations, and environmental compliance and performance in a remote area of the North Slope. Unlike most North Slope operations where there is existing infrastructure, this Project will have to be self-sufficient. The proposed infield roads, pads, gathering lines and facilities are essential for safe and effective operations in this remote location. The infield gathering lines are needed to connect the pads for production flow testing and actual production. An infield gravel road system is required to provide a reliable year-round means to transport personnel, equipment and rigs among field locations in support of drilling, operations, safety and emergency response activities. The airstrip is critical for all-season access and emergency response. Lastly, the PTEP has been designed to be a direct route to Badami with the minimal number of VSMs in active stream channels.

As described below, Section 404 regulated discharges or structures associated with the Project include: gravel facilities (pads, roads, associated bridges and culverts, airstrip), VSM placement for infield gathering lines and the PTEP, dredging and screeding for safely grounding and docking barges[8], trenching for power and other cables, timber sleepers to support galvanized rigid steel conduit between the aircraft approach lights at the ends of the airstrip; steel piles installed in the tundra to support aircraft approach lights, concrete/gravel associated with the boat launch and the gravel mining operation. Spoils generated during drilling of holes for VSMs will be collected and deposited at the inorganic overburden stockpile for disposal in the mine site or other approved locations.

Section 10-regulated structures include the driven pilings for dolphins associated with the Barge Offloading Facility and Service Pier, and that portion of the concrete and gravel below mean high water (MHW) for the boat launch.

PTEP Gravel Infrastructure

Processed hydrocarbon fluids will be delivered to BSOP and ultimately to TAPS through the PTEP. The PTEP will be supported on approximately 2,200 VSMs as it runs from the CPF to BSOP connection point (Figures 31-33). The gravel footprint of these VSMs is a minor part of the overall Project footprint.

Survey crews mark the VSM's location on the ground; drilling crews drill holes to the designed depth with either air drills or regular auger drills. After placement of the VSM into the hole, a slurry mix of sand, aggregate, and water is poured from a mixer truck into the annulus around the VSM and vibrated to remove any air pockets. The slurry then freezes and holds the VSMs in place to support the pipeline(s). Spoils are collected from the snow surface and will be transported to the Point Thomson gravel mine, combined

[8] This activity is subject in part to both Section 404 and Section 10. The dredging and screeding activity is below mean high water, thus subject to Section 10, and the disposal of dredged and screeded material is above mean high water, thus subject to Section 404.

with overburden, and placed in the gravel mine as part of the reclamation plan or disposed at other approved locations.

The small PTEP Auxiliary Pad (estimated to be less than 0.3 acres) and another small (40 feet x 40 feet) pipeline crossing pad at Badami are the only structures, in addition to the drilled and slurried VSMs, involved in the construction of the PTEP that will result in discharges to Waters of the United States. Figures 29–30 show these Pads in greater detail. The purpose of the Auxiliary Pad is to provide space to install a leak detection metering skid. The small 40 feet x 40 feet pipeline-crossing pad provides a platform for rigs to safely pass over the pipeline to facilitate continued production development at Badami.

IPS Gravel Infrastructure

Most surface facilities will be located on gravel pads (exceptions include pipeline supports, timber sleepers for power lines to airstrip approach lighting and water lines, temporary ice pads and roads, and the offshore piling associated with the sealift module bulkhead and the Service Pier). Gravel pads, infield gravel roads, and the gravel airstrip will provide stable platforms through the Project design life. Gravel for these structures will be extracted from a new mine site (Figures 61-66). See Figure 6 for quantities of gravel extracted and quantities of gravel needed to build these structures.

The three main gravel pads associated with the IPS are the Central (Figures 7-8), East (Figures 17-18) and West Pads (Figures 19-20). These pads will support drilling facilities. In addition to supporting drilling facilities, the Central Pad will also provide a foundation for the CPF facilities and infrastructure to process fluids produced from the wells at Central, West and East Pads (Figures 7-8). The Central Pad is provided with slope protection for storm surges (Figures 9-10). The West Pad and the operational portion of the East Pad are set back from the coast to avoid coastal erosion over the Project life. The very conservative design criteria used as the basis to site these pads with respect to coastal erosion and storm surge is described in Section 4.5.3.2., of the *Environmental Mitigation Report* (Appendix A) and repeated below:

> 4.5.3.2 Planning and Design for Coastal Erosion
>
> Design criteria for the East and West Pads include accommodating LRDD for field development and sufficient setback from the coast to avoid the effects of coastal erosion, storm surge and wave run-up, and ice ride-up/pile-up.
>
> The new section of gravel fill for East Pad was located 250 feet from the coast, extending along a trend of higher ground to provide a buffer against coastal erosion over the life of the Project. East Pad is also located on high ground such that 100-year storm surge and wave run-up

are not expected to reach the pad[9]. The West Pad setback from the coast was 410 feet, which was determined by the 100-year storm surge and wave run-up, combined with the eroded shoreline location after 30 years. Slope protection is not required due to the higher elevation and the setback distance. Critical facilities at both pads will not be exposed to ice during a 100-year ice ride-up event.

Based on the average coastal erosion rate over the period of record (1955 to 2009) shoreline erosion is determined to be about 2 feet per year for the East Pad and 4 feet per year for West Pad. Using this average erosion rate, pad setback is sufficient to provide protection of critical facilities from coastal erosion for more than 80 years. However, to be conservative, ExxonMobil considered the worst-case erosion rates predicted to occur over the Project's 30-year design life. The worst-case erosion limits were determined by taking the maximum erosion rate observed (representing time periods of as little as 3 years) within the period of record (1955 to 2009) and applying that erosion rate over the entire Project life. Under this conservative design basis, the pad setback is sufficient to provide protection from coastal erosion during the 30-year design life.

Other siting and design factors include storm surge and wave run-up. East Pad is at +17 feet, Mean Lower Low Water (MLLW) elevation and is above the 100-year return storm surge and wave run-up limit. West Pad is at +20 feet, elevation and is above the 100-year return storm surge and run-up limit.

Because the Central Pad was designed to incorporate the existing PTU-3 Pad and to be close to the coast for barge access and launching emergency response boats, it was not possible to fully avoid coastal erosion by pad setback. Nonetheless, the existing pad will be elevated by adding 5 feet of gravel in order to be above the 100-year storm surge and wave run-up elevation.

The slope protection proposed for the Central Pad generally relates to protection from run-up and overtopping of storm surge events more than retreat of the coastline due to erosion. During the life of the Central Pad, coastal erosion will be monitored and mitigation will be employed if erosion begins to threaten the pad. Critical facilities will not be exposed to ice during a 100-year ice ride-up/pile-up event.

[9] The eastern edge of the North Staines River No. 1 Pad is susceptible to coastal erosion over the Project life, which makes it unsuitable for well and pipeline installation, but is sufficiently set-back for temporary use, such as drilling rig camps or staging/storing supplies (Section 4.2.3.2 East Pad, Environmental Mitigation Report).

Three additional pads to support construction and operations are the Alaska State C-1 storage pad (Figures 25-26), Water Access pad (Figures 27-28), and the Gravel Stockpile Pad (Figures 61-66). These pads, which are inland and not subject to coastal erosion, will be used for long-term equipment storage, year-round access to the water supply, and storage of gravel to be used for maintenance of all gravel structures.

A year-round gravel airstrip is essential for the transport and safety of personnel, transport of supplies, and for emergency response (Figures 21–24). Based on Federal Aviation Administration advisory circulars and aircraft operator's safety guidelines, the airstrip's surface dimensions will be approximately 5,600-feet long by 200-feet wide, with an apron, helicopter parking area, lighting, air traffic control building, and control and communication links to the Central Pad. After the gravel runway has been constructed, pilings for navigation aids (navaids) and approach lighting will be installed. Approach lighting pilings are placed at approximately 200 foot intervals with power and control cables contained in steel conduit supported on 12-inch by 12-inch by 6-foot timber sleepers, placed directly on the tundra, at approximately 10- to 20-foot intervals. To provide slope protection, organic overburden with jute mat and/or organic overburden without jute mat from the gravel mine will be placed along the south and north edge of the airstrip and seeded to promote revegetation.

All-season gravel roads will connect the IPS pads, airstrip, gravel mine, and freshwater supply source(s) to the Central Pad (Figures 43-49). Approximately 12 miles of in-field gravel roads will be constructed within the IPS area. Minimum fill depth of the roads is 5 feet with a 2H:1V slope ratio.

Bridges and Culverts

Cross-drainage culverts consisting of structural line pipe will be located, on average, at 500-foot intervals along the Project gravel roads to mitigate potential water impoundment. The distance between cross drainage culverts will vary slightly, based on site-specific conditions (Figures 43-48).

The Project area that will be impacted by gravel roads contains nine small, defined tundra streams that originate on the ACP. Four of these streams contain gravelly bottoms, while five have grassy bottoms. Bridges and culverts at stream crossings will be designed for a 50-year flood design flow to reduce impacts to natural drainage to the extent practicable.

The gravelly-bottom streams indicate sediment transport and have higher water flows, particularly during breakup, and infield roads will cross these streams using bridges 40 to 65 feet in length (Figures 50-54). Bridges will be designed with clear openings between vertical sheet pile abutments, with openings 15 feet shorter than the bridge length. The piles supporting the bridge girders will be placed behind the sheet piles, with no obstructions in the stream channels.

The grassy bottom streams indicate little to no sediment transport and commensurately lower flows, and infield road crossings will utilize culverts (Figures 55-60). Two streams containing fish will be provided with hybrid culvert batteries designed for fish passage.

Streams crossings 18A and 24A will use structural steel line pipe culverts, with a single corrugated, multi-plate culvert to meet fish passage criteria. The multi-plate culvert will be installed along the thalweg of the drainage. Culverts for the other three streams (Streams 23, 26, and 27) will use structural steel line pipe.

Gathering Lines

Hydrocarbons that are produced from wells located on the East and West Pads will be delivered to the CPF via gathering lines (which are also referred to as flowlines) (Figure 4). The 8-inch nominal diameter gathering lines are sized to handle production from a single production well. The gathering lines will be supported on VSMs, similar to the proposed PTEP. The VSMs will be designed and installed to provide at least 7 feet of clearance between the lowest point of any element being supported by VSMs (e.g., pipe insulation, including pipeline attachments such as tuned vibration absorbers, electrical communication cables, etc.) and the ground surface.

The vertical support may be single or dual pipe 8” to 12” in diameter depending on the configurations of pipelines on each VSM and site-specific geotechnical conditions. The gathering line VSMs will be spaced at approximately 55-foot intervals and are designed to minimize placement within the active channel of stream crossings. The gathering line VSMs will have single vertical pipe supports except that approximately every 2,000 feet (where anchors are placed in between Z bends) the VSM vertical support will be dual pipes. Locations for these VSM/gathering line configurations are shown in Figures 33-34. VSMs will be installed in the same manner as described above for the PTEP.

Sealift Barge Facilities

The Project will require the use of oceangoing barges for sealift of large, pre-fabricated facility modules. The oceangoing barges are considerably larger than the coastal barges, with deeper hulls, and can carry heavy loads with a relatively shallow draft during transport and delivery to the site. Ocean barges that are approximately 25 feet deep, 105 feet wide, and 400 feet long will be used for sealift of large modules and heavy equipment to the Point Thomson site.

Loaded ocean barges require several feet of draft and cannot directly access the beach. For landing and securing ocean barges, an onshore (above MHW) Sealift Bulkhead and four offshore mooring dolphins will be constructed (Figures 11-13). The Sealift Bulkhead will be made of sheet pile in an OPEN CELL® design, with a gravel backfill transition to the Central Pad surface. Shore protection will consist of a combination of sheet piles on the seaward face of the abutment and gravel bags on the east and west faces of the sealift bulkhead. The modules will be offloaded via a barge bridge system, which is a configuration of up to three barges linked end to end and temporarily connected to this bulkhead by a ramp. The three barges making up the barge bridge system will be temporarily grounded in place during the offloading operations.

Dolphins for mooring/breasting the barges are needed to ensure an accurate alignment of the barges for offloading operations and will be left in place for future use (Figure 13).

Dolphins will be installed in water depths of approximately 4 feet closest to shore and in water depths of approximately 7.5 feet furthest from shore using typical North Slope methods (i.e., driving piles or drill and slurry, through the ice in winter). For any dolphin installed by drill and slurry, the drilling spoils will be placed in the designated dredge spoil placement area as shown in Figure 14. If additional structural support between the sealift abutment and the first grounded barge is deemed necessary to support the loading ramp, then up to 6 temporary piles parallel to shore at a distance of 40 feet from the sealift abutment may be installed during construction using typical North Slope methods. These will be cut off 5 feet below the mudline or removed during the construction phase after all facility modules are transported to the Central Pad.

Service Pier

A Service Pier for offloading the smaller coastal barges will be constructed adjacent to the Sealift Bulkhead (Figures 11-12). The Pier will allow more fully loaded coastal barges (up to 800 tons) to access the site, substantially decreasing the number of seasonal coastal resupply barge trips, and can accommodate loads up to 1,100 tons as may be needed during construction. The docking facility will consist of a 120-foot long by 30-foot wide pier, extending approximately 70-feet offshore of the Central Pad shoreline. The Service Pier will be supported by nine vertical piles (six offshore and three onshore) which will be driven or drilled in the winter from grounded ice. The footprint of the three onshore piles is assessed in Tables 3 and 4. Four mooring dolphins will be driven or drilled to extend docking options to assist in securing barges. The deepest dolphin will be in a water depth of approximately 4-feet.

Dredging and Screeding

Barges transporting modules, equipment, materials or supplies to Point Thomson require a specified draft for offloading. Minor or shallow dredging, if needed, will be used to provide the required seabed depth profile. The actual dredging requirements can be expected to vary due to the changing coastal processes (sediment transport and storms) in the Beaufort Sea and will be determined on an annual basis. The permit application volumes are based on maximum (conservative) estimates.

Sealift barges transporting modules to the Sealift Bulkhead will be grounded and require 6 feet of water depth for the barge closest to shore. The sealift barges require a level seabed to safeguard the structural integrity of the barges. Coastal re-supply barges transporting equipment, materials or supplies to the Service Pier require a minimum 4 feet water depth to access the Pier. The coastal barges typically will not be grounded, however there may be a need to ground or ballast down coastal barges delivering certain modules such as the camp and tank modules that may exceed 800 tons. In such cases the barges will use local water if ballasting and de-ballasting is required.

Dredging and screeding will be conducted during the first winter construction season (through the ice) and could occur during the following second and third winter construction seasons in front of the Sealift Bulkhead and, possibly, in front of the Service

Pier. The area where screeding and/or shallow dredging could occur is approximately 154,000 square feet and starts at a location approximately 40 to 60 feet from the Sealift Bulkhead seaward (north) to about 500 feet, and in front of the Service Pier seaward (north) to about 300 feet, as shown on Figure 11.

Not all of the ice in the designated dredge area can be removed at the same time. Therefore, dredging and screeding will be conducted sequentially in different areas. As a result, in order to achieve the needed seabed profile, some of the dredged material may need to be temporarily placed in the onshore dredge spoils placement area (described below). As another area of the seabed is exposed after ice removal, some of these dredge materials may need to be placed back in the dredge area to fill low spots if insufficient dredge material at the work site is available. Thus there may be some double handling of dredge materials. The maximum dredged volume requiring disposal after dredging is completed to establish the needed seabed profile is conservatively estimated not to exceed 1,500 cubic yards (cy) during any construction season.

During construction, screeding and, possibly, some dredging may be needed in summer in the area in front of the Sealift Bulkhead prior to arrivals of the barges, and periodically throughout operations in front of the Service Pier. If summer dredging is needed, the maximum volume is conservatively estimated to be about half of that estimated for dredging during the winter construction season, or 800 cy.

The seabed material remaining after dredging and filling will be placed along the nearby shoreline above MHW. A stretch of beach approximately 0.75 miles west of the area dredged is proposed for dredged material disposal (Figure 14). Coastal studies indicate that this site far enough away from the barge offloading facilities that the dredged area would not be refilled from this deposited material. The disposal location may vary based on dredging season and volume, but approval will be sought from the USACE and ADNR prior to placement of spoils onshore.

Boat Launch

The Boat Launch will consist of an approximately 24-foot wide gravel/concrete panel ramp extending approximately 165-feet from the Central Pad into the bay to approximately 3.5-feet below the MLLW level (Figures 15-16). The Boat Launch will consist of a 108-foot long gravel ramp with concrete planks (24-feet wide by 57-feet long) extending into the water as a running surface. This facility will be adequate for launching the smaller emergency response vessels that will be stationed at Point Thomson. This location is in a protected lagoon, which affords an ideal access to launch these vessels.

Other Fill

Power cables to the water source and airstrip will be trenched; the trenching materials will be placed back into the trenches. Cables to navaids will be placed on 12-inch by 12-inch by 6-feet timber sleepers (Figure 24). The sleepers are placed at 10- to 20-foot

intervals. See Figures 67-68 for the Electrical Power Plan and Electrical Power Sections in relation to trenching of tundra.

Gravel Mine Site

Appendix B provides the *Point Thomson Project Mining and Rehabilitation Plan*. Gravel mining is planned to occur over a two-year period. Overburden will be placed on single-season ice pads during each year of mining. At the conclusion of the mining for each year, the overburden will be placed back into the mine pit and the ice pad will be allowed to melt during the summer season. The mine site will be rehabilitated following completion of mining activities. Should a change in construction plans require some additional mining of gravel or expansion of the mine beyond the second year, the mine may be left open and the rehabilitation completed when appropriate.

Approximately 200,000 cy of gravel will be stockpiled for future maintenance needs on an approximately 12.9-acre area adjacent to the mine site and accessible by the gravel mine access road (Figure 61). As gravel is consumed over the years, the vacated area may be used for storage and staging of equipment and materials. The gravel stockpile area could also serve as an expansion area for the Mine Site for future development (i.e., a new cell).

Project Component Figures

The set of figures in this application include site maps, plan views and cross-sections for all gravel structures, including the roads, airstrip, Central Pad, East and West pads, gravel maintenance stockpile, mine site overburden, and components for barge offloading and boat launching. Table 3 provides the Project gravel footprint by vegetation type in acres. See Tab 21 Discharged Materials and Table 4 for a further description of the Project footprint and gravel placement requirements. The Central and East Pads will involve construction over, and expansion of, the existing PTU-3 Well Pad and North Staines River State No. 1 Pad, respectively. The existing Alaska State C-1 Pad will receive additional fill for leveling but will not be expanded in area.

Timber Sleepers	(placed on tundra)	<0.1	Wood	Loader and Manpower
Gathering Line and Export Pipeline VSMs	3,600	0.1	Sand Slurry and Steel	Power Auger hole, place VSM, then place slurry from Mixer Truck
Badami Auxiliary Pad and Pipeline Crossing Pad	3,100	0.4	Gravel Fill	Dump Trucks, Fill Dozer, and Graders
Gravel Mine Footprint	(extracted)	49.6	Gravel Fill	Dump Trucks, Fill Dozer, and Graders
Gravel Mine Access Road Footprint and Fill	23,000	3.3	Gravel Fill	Dump Trucks, Fill Dozer, and Graders
Gravel Stockpile Footprint	204,000	12.9	Gravel Fill	Dump Trucks, Fill Dozer, and Graders
[4]Organic Overburden Stockpile	105,000	(on ice pad)	Organic Materials	Dump Trucks, Fill Dozer, and Graders
[4]Inorganic Overburden Stockpile	937,000	(on ice pad)	Inorganic Materials	Dump Trucks, Fill Dozer, and Graders
TOTAL	**3,300,500**	**267.5**		

[1]This pad will be constructed using an existing pad structure.

- Central Pad footprint will encompass the entire existing 13.2 acre PTU-3 gravel pad.
- East Pad footprint will encompass 4.63 acres of the existing 4.8 acre of North Staines River State No. 1 gravel pad.
- Alaska State C-1 Pad will not have any additional footprint. It will encompass the entire existing 4.1 acre Alaska State C-1 Pad.

[2]During construction, up to 1,500 cy will be placed annually in 2012, 2013 and 2014. Annual maintenance of the Service Pier may require up to 800 cy of material to be dredged per year after 2014. The seafloor footprint of dredging and screeding will be 3.2 acres. The seafloor footprint of screeding will be 2.3 acres.

[3]The area affected by the three Service Pier piles that are onshore are shown here, the six additional piles will be offshore.

[4]The inorganic and organic overburden stockpiles will be placed on a seasonal ice pad during the development of the gravel mine. This area is not taken into account in Table 3 as a footprint affecting vegetation because of its seasonality (one year). When rehabilitation of the gravel mine takes place, the overburden will be considered fill, as it is placed within the mine's pit.

TAB 23: MITIGATION STATEMENT

Introduction

This mitigation statement describes the appropriate and practicable steps ExxonMobil proposes to avoid and minimize potential adverse impacts to the aquatic ecosystem and Waters of the United States, including wetlands, for the proposed discharge of fill for the Project. ExxonMobil's statement describing how unavoidable impacts are to be compensated is set forth at the end of this Tab.

Supporting Documents

ExxonMobil's *Environmental Mitigation Report (June 17, 2011)* (Appendix A) submitted to USACE provides comprehensive information on how the Project is designed, and will be constructed and operated, to avoid and minimize impacts of fill into Waters of the United States. Section 4.2 (Wetlands and Other Waters of the U.S.) specifically addresses minimization of aquatic impacts. The Report also describes how the Project has minimized impacts to waters and wetlands in closely related areas including Hydrology (Section 4.3), Water Quality (Sections 4.4), and Physical Oceanography and Coastal Processes (Section 4.5). Other sections of the EMR discuss mitigation of impacts to additional resources in the Project area which, given the extensive reach of wetlands, may also be regarded as relevant. Appendix A in the EMR provides a cross-reference to sections of the report that provide relevant information and mitigation measures that demonstrate the Project's compliance with applicable requirements of the 404(b)(1) Guidelines (40 Code of Federal Regulations [CFR} Part 230). Therefore, the EMR is appended to this USACE application (Appendix A) and incorporated by reference.

ExxonMobil's *Section 404(b)(1) Practicability Analysis of Point Thomson Project Preliminary Draft Environmental Impact Statement Alternatives (May 13, 2011)* provides a comprehensive analysis of the practicability of the Alternatives identified in the Point Thomson Project Preliminary Draft Environmental Impact Statement (PDEIS), which were developed by the Lead Federal Agency and Cooperating Agencies. The Alternatives may be seen as different conceptual approaches to the Project and its components considered for potential minimization of impacts. The Practicability Analysis is therefore relevant to whether the Project could incorporate other practicable means to avoid or minimize impacts. No identified Alternative provides for a Project location outside of jurisdictional wetlands, nor for reasons set forth below is this possible. In addition, while a determination of the least environmentally damaging practicable alternative is the responsibility of USACE, the Practicability Analysis identifies practicality concerns and additional environmental impacts that could result from the Alternatives to the proposed Project. The Practicability Analysis is also incorporated by reference including relevant Bar Charts illustrating the practicability of the PDEIS Alternatives.

ExxonMobil's *Environmental Report (November 2009)* provides ExxonMobil's analysis of relevant environmental impacts of the Project particularly with respect to the Affected

Environment (Chapter 3), Environmental Consequences (Chapter 4), and Cumulative Effects (Chapter 6).

ExxonMobil has also supported the National Enviromental Policy Act (NEPA) and 404-review processes with submissions of technical information, responses to requests for information (RFIs) and workshops[10]. Of particular relevance are the following:

- Hydrology Workshop, March 8, 2011
- Gravel Mining and Rehabilitation Plan Workshop, March 15, 2011

Spill prevention is the primary approach for Project oil spill preparedness. However, to be ready for any spills that may occur, comparable efforts are put into developing contingency plans used to respond to spills and providing training to personnel to ensure the prevention and response plans will be effectively implemented. The *Point Thomson Oil Spill Preparedness* report, attached to the Biological Assessments prepared for the project, describes the prevention capability incorporated into the design (such as containment), and the prevention and response measures to be implemented at Point Thomson through the construction, drilling and operations phases. Each of these phases will have one or more separate management processes addressing spill prevention and response. Representative subjects covered include:

- Spill Prevention During Fuel Transport, Storage, and Use;
- Training and Special Programs for Prevention (for example for ice roads and barging);
- Response Plans;
- Oil Spill Response Capability and Measures;
- Design and Operational Controls for Pipeline Corrosion and Leak Detection; and
- Drilling Prevention Measures, including Well Planning, Drilling Rig and Well Control/Blowout Prevention Equipment.

[10] ExxonMobil support in the EIS Process:

- Developed detailed analysis of the practicability of EIS Alternatives
- Presented to the Corps and Cooperating Agencies an in-depth Practicability and Cost Analysis to support Project as Least Environmentally Damaging Practicable Alternative
- Responded to 81 Requests For Information (RFI) and 21 follow-ups on a wide range of Project and facility related questions and environmental topics
- Hosted 20 workshops to discuss Project execution and the design rationale of select components and provided 10 technical briefs on key aspects of the Alternatives
- Provided conceptual execution planning for the 3 proposed EIS “action” Alternatives
- Facilitated/funded a variety of field studies to support the EIS and related processes including Wetlands Vegetation Mapping, Noise Study, Visual Assessment, Eider Survey, Yellow-Billed Loons Survey, and Fish Study

Project Siting

Siting of Project facilities was based on the location of the Thomson Sand reservoir, a predominantly offshore reservoir under the Beaufort Sea. As discussed under Tab 20 (Reason for Discharge), it is not possible to avoid development in wetlands while still allowing necessary access to the reservoir and meeting Project (Applicant) purpose and needs.

Optimal placement of drilling pads would be offshore, directly over the bulk of the reservoir. However, ExxonMobil has elected not to place pads in offshore waters. The next best placement of pads that can still access the reservoir is on the ACP. The nearest extensive upland areas (i.e., areas with limited jurisdictional wetlands) are in the northern foothills of the Brooks Range, approximately 20 miles south of Central Pad. This distance is far beyond the technological capabilities of LRDD or practicable placement of non-drilling facilities.

The Project is intended to initiate commercial production of the Thomson Sand reservoir in the PTU. Closely related purposes of the Project are to delineate and evaluate hydrocarbon resources and to provide a footprint for reasonably foreseeable future full field development of the reservoir. The PTU -- a unitized field approved under Alaska law to ensure coordinated development of its hydrocarbon resources -- comprises an authorized area of unitized development extending from offshore in territorial waters (State waters) of the Beaufort Sea to onshore areas south of the coastline. All areas of the PTU are within jurisdictional Waters of the United States, including wetlands, and are miles removed from any uplands areas to the south.

The Project is a remote site development located in an isolated area of the eastern Beaufort Sea coast. The nearest connection to an existing road network and support infrastructure is over 40 miles away at Endicott Spur/Prudhoe Bay. The PTU and Project area are currently accessible only by helicopter and in limited seasonal windows by means of summer coastal barging, winter ice roads, and limited inefficient tundra travel. Maximizing use of these limited access opportunities is paramount for achieving practicable logistics and costs for construction, drilling and operation of the proposed Project. In particular, as the Practicability Analysis demonstrates, coastal barging and supply access are essential to the Project. The only other alternative means to provide adequate supply access which is not restricted to narrow seasonal windows for ice roads is a gravel road to Prudhoe Bay, which would have a far greater impact on wetlands than the proposed Project. Coastal barging has been successfully conducted for three years during the recently completed Point Thomson drilling program under applicable provisions of a Conflict Avoidance Agreement with the Alaska Eskimo Whaling Commission with little to no environmental impact or impacts on subsistence. In sum, coastal access is essential to the Project.

Recently drilled wells on the existing Point Thomson Central Pad, PTU 15 and PTU 16, are located on the coast in Lion Bay in the central part of the Unit. These wells are intended to be used for commercial production in the proposed Project, one as a production well and the other for reinjection of high-pressure gas back into the field after

removal of liquid hydrocarbons. The wells cannot be moved. Although proposed production facilities could technically be separated from the Central Pad and located on a new, additional pad, this would increase wetlands footprint both in size and geographical scope. The two pads would together be larger than the single proposed expanded Central Pad, due in part to inefficiencies associated with dual pads. The pads would also need to be connected by much longer high pressure production and reinjection pipelines, and would create dual sources of additional impacts [ExxonMobil's *Section 404 (b)(1) Practicability Analysis of Point Thomson Project Preliminary Draft Environmental Impact Statement Alternatives (May 13, 2011)]*.

Additional drilling sites for the Project are proposed to be located on the East and West pads. The proposed East pad location enables utilization of an existing drill pad, North Staines River No. 1. Pad location further inland from the coast would increase the horizontal departure on wells and potentially preclude the ability to reach portions of the reservoir necessary for full field development. This could lead to additional pads being needed in the future to reach bottomhole targets that cannot be reached from a pad that has been located further inland. As explained in Tab 20, IPS Gravel Infrastructure, the design and siting criteria for Project pads establishes more than adequate setback with respect to coastal erosion and storm surge.

The ADNR has addressed the extent to which the three existing and proposed pad locations can, by means of LRDD, enable reach of the full reservoir and full development of the field [ADNR Response to Point Thomson Project Environmental Impact Statement (EIS) Request for Information 63]. The State has concluded that, for a high-pressure field such as Point Thomson, LRDD technology is limited to approximately 13,000 feet of reach, and that moving the drilling pads inland could likely impact the ability to adequately access and develop the Point Thomson reservoir[11]. As a cooperating agency in the EIS review of the Project, the State of Alaska may be regarded under NEPA as having jurisdiction by law and special expertise in the regulation and management of its oil and gas fields. For purposes of NEPA review the State's conclusions here should be entitled to deference in this technical area [see 40 CFR 1501.6(a)(2)].

Water Dependent

The Section 404(b)(1) Guidelines provide that, for non-water-dependent activities, "practicable alternatives that do not involve special aquatic sites are presumed to be

[11] The State's response to RFI 63 states in relevant part:

"A search of recent examples of drilling in similar high pressure reservoirs elsewhere in the world reveals current technology limits drilling departures to approximately 13,000 feet. From this standpoint, it is reasonable to assume that requiring the proposed drill pads to be located further south from the coastline could likely impact the ability to adequately access and develop the Point Thomson reservoir.

…[T] he drilling departures proposed by Exxon for this project appear achievable, but near the limits of those drilled in high pressure reservoirs elsewhere."

available" and "all practicable alternatives to the proposed discharge which do not involve a discharge into a special aquatic site are presumed to have less adverse impact on the aquatic ecosystem, unless clearly demonstrated otherwise" (33 CFR 230.10(a)(3)). Here, for the reasons just stated, no alternatives that do not involve special aquatic sites (wetlands) are available, and there is accordingly no alternative which might be presumed to have less adverse impact on special aquatic sites.

The Section 404(b)(1) Guidelines also provide that activities proposed for a special aquatic site, including wetlands, that "do not require access or proximity to or siting within the special aquatic site in question to fulfill its basic purpose" are not ‘‘water dependent’’ (33 CFR 230.10(a)(3)[12]). ExxonMobil respectfully submits that under the plain language of the regulation, the Project should properly be considered "water dependent." Here, the basic purpose of the Project is to initiate commercial hydrocarbon production of the Thomson Sand reservoir in the PTU. The Thomson Sand reservoir is predominantly under the Beaufort Sea. Coastal drilling pads are necessary to maintain full access to the reservoir. Coastal barging access is essential to the practicability of the Project. The Project therefore requires "access or proximity to or siting within the special aquatic site in question to fulfill its basic purpose." See *Friends of the Earth v. Hintz, 800 F.2d 822 (9th Cir. 1986)* (upholding USACE determination that log storage facility was water dependent because export of logs required proximity to water).

ExxonMobil nevertheless recognizes that USACE, in draft documents to date, has considered that the Project is not water dependent. In the alternative, the circumstances presented here clearly demonstrate that the presumptions established for non-water-dependent activities are not applicable.

Relationship between Project Logistics and Wetlands Footprint

It is important to understand that the Project strikes a balance between the smallest wetlands footprint achievable and the need for practicable logistics with year round access essential to build and safely operate a remote development in the Arctic.

The Project is located in a remote area currently accessible only in limited seasonal windows by means of winter ice roads, summer barging and early winter tundra travel. Further, these brief seasonal windows are uncertain due to unpredictable variations in weather, ice conditions and wildlife interactions. Helicopters provide the only current year-round access mode, but can be grounded by weather for lengthy periods.

[12] (3) Where the activity associated with a discharge which is proposed for a special aquatic site (as defined in subpart E) does not require access or proximity to or siting within the special aquatic site in question to fulfill its basic purpose (i.e., is not “water dependent”), practicable alternatives that do not involve special aquatic sites are presumed to be available, unless clearly demonstrated otherwise. In addition, where a discharge is proposed for a special aquatic site, all practicable alternatives to the proposed discharge which do not involve a discharge into a special aquatic site are presumed to have less adverse impact on the aquatic ecosystem, unless clearly demonstrated otherwise.

Maximizing use of these limited and seasonal access opportunities has played a significant role in planning for Project logistics and execution. This is essential to achieve practicable logistics and to minimize Project execution risk. This also directly contributes to minimizing wetlands footprint and other adverse environmental effects.

For long-term operations, these current means of access are augmented by an airstrip and infield roads to the drilling pads. These comprise the minimal footprint for year-round and emergency access, both to and within the Project, essential for long-term operation of a remote development in the Arctic. This design footprint also minimizes other adverse environmental impacts which would arise from more restricted access.

How the Project's logistics plan, efficient execution, and use of all available modes of transportation synergistically work together to minimize wetlands footprint is described in further detail in the minimization section below.

Avoidance of Impacts to Waters of the United States, Including Wetlands

Please describe how, in your project planning process, you avoided impacts to Waters of the United States, including wetlands, to the maximum extent practicable. Examples of avoidance measures include site selection, routes, design configuration, etc.

As discussed above, there are no practicable, non-wetland alternatives to the proposed Project. However, ExxonMobil has avoided impacts by eliminating three major development options or components included in earlier development proposals. As described in Section 3.0 of the EMR, the following components were eliminated from the proposed Project, avoiding related discharges to Waters of the United States:

- Offshore development potentially including gravel islands, drill sites on barrier islands, and/or subsea pipelines;
- Solid fill dock and dredged approach channel; and
- Gravel access road to/from Prudhoe Bay.

In addition, providing optimum access to reservoir resources through LRDD from pads on the coast avoids the potential future need for additional drilling pads to support full field development, which could be required if the initial drilling pads were located further inland.

Minimization of Unavoidable Impacts to Waters of the United States, Including Wetlands

Please describe how your project design incorporates measures that minimize the unavoidable impacts to Waters of the United States, including wetlands, by limiting fill discharges to the minimum amount/size necessary to achieve the project purpose.

Effective minimization of unavoidable impacts to wetlands is accomplished in two primary ways as described below. The first is through the Project's civil works, which have been designed to maintain area wide hydrologic flow with the minimal wetlands footprint practicable. The second relates to Project logistics and the complex relationship

between wetlands impacts and the efficient execution of Project activities using all available modes of transportation.

Environmental Performance of the Project Design

Because it is not possible to completely avoid discharging fill in wetlands, the Project has minimized impacts to the extent practicable. Related mitigation measures include optimizing Project design to reduce the extent of discharge and associated environmental impact, while meeting Project needs. Additional details and explanation of the rationale and effect of these mitigations are provided in Appendix A - *Point Thomson Project Environmental Mitigation Report*.

The three processing and/or drilling pads are the minimum size necessary to meet required drilling and processing needs. Two of these three pads utilize existing gravel pads, minimizing overall new fill requirements. Another existing pad (Alaska State C-1 pad) will be used to provide valuable storage space, with a minimal volume of new gravel fill required and no new footprint. The proposed three-pad configuration (Central, East and West Pads) is also expected to meet reasonably foreseeable future field development scenarios (e.g., expanded gas cycling and/or gas sales). These pads, combined with LRDD technology, allow the hydrocarbon resources to be evaluated and developed with minimal future gravel expansions.

The 5,600-foot Project airstrip accommodates the size aircraft needed to meet Project needs (DC-6 equivalent for cargo and Dash 8 or equivalent for personnel). It also is the minimum needed to accommodate the civilian equivalent of the C-130 Hercules (L100-30). L100-30s are essential for expeditious delivery of heavy equipment, supplies and other support in the event of an emergency response. Reducing the length of the airstrip limits flights to 5,000-lb. loads, which increases the number of flights for general cargo or passenger flights by a multiple of four. Elimination of the heavy cargo capacity aircraft limits capabilities to respond to emergencies.

Some gravel pads originally proposed for navaids have been eliminated or replaced with piling-supported structures to accommodate the local hydrology, which also reduces wetlands footprint. The infield gravel road system is the minimum required (approximately 12 miles) for efficient and safe year-round Project operations. Additional information provided in Section 4.3.3.2 of the EMR explains the tradeoff between road length and routing criteria. The Project mine site was located to minimize footprint while meeting gravel quantity and quality requirements. It also is being designed to be a high functioning wetland and wildlife habitat when rehabilitated.

Wetlands

Key mitigation measures in minimizing impacts to wetlands and other Waters of the United States include the following, which are described in more detail in section 4.2 of the EMR.

- Minimizing gravel fill by utilizing three existing gravel pads in the area thereby reducing overall new tundra footprint by more than 20 acres.

- Minimizing the size of the gravel pads through optimizing Project design and equipment layout.
- Designing pads, roads, bridges and culverts to maintain natural drainage patterns and stream flows to the extent possible.
- Routing the infield gravel roads to minimize overall length and footprint, with consideration for hydrologic impacts and Project needs.
- Combining the East Pad Road with the Central Pad Road, minimizing hydrology impacts without increasing the tundra footprint.
- Routing the West Pad Road to avoid coastal marshes and estuarine habitat, while minimizing the wetlands footprint and hydrologic impacts.
- Utilizing ice roads and pads for Project access, pipeline construction, and temporary storage of mine site overburden.
- Watering gravel roads and pads, as necessary, to control dust generation.

Hydrology

Mitigation of impacts to hydrology is also a consideration with respect to avoidance or minimization of impacts to wetlands and other Waters of the United States. These mitigation measures are described in more detail in Section 4.3 of the EMR. The Project has been designed with engineering care, supported by field surveys, in placement of facilities, particularly the infield roads, and the location and design of bridges and culverts to assure maintenance of the hydrologic regime. Key mitigation measures include:

- Routing the infield gravel roads to minimize overall length and footprint, with consideration for hydrologic impacts and Project needs.
- Conducting field surveys during breakup and other times to identify natural drainage patterns and to measure stream flows at proposed road crossings (Figures 43-48).
- Routing infield roads a sufficient distance inland to avoid major stream crossings.
- Balancing the avoidance of lakes, ponds, and wetter tundra areas closest to the coast with avoidance of areas further inland where unconcentrated overland flow predominates.
- Designing bridges and culverts at stream crossings for a 50-year flood design flow to reduce impacts to natural drainage to the extent practicable.
- Installing cross-drainage culverts at approximately 500-foot intervals along the road system to maintain overland flow.
- Several bridges and culvert batteries were redesigned to enhance environmental performance even though they already exceeded the Project's hydrologic performance requirements:

  - Two culvert batteries (18A and 24A) were redesigned as hybrids to include both line pipe for structural support and a corrugated multi-plate culvert for fish passage.
  - Bridge 22A was lengthened and the abutment further set back from the channel to provide a wider riparian corridor.
  - Bridge 24B was lengthened to further minimize backwater, sediment transport, and erosion potential.
- Using a sheet pile design for bridge abutments to minimize the tundra footprint, road embankment erosion and stream scour.
- Slotting ice roads at designated stream crossings to facilitate drainage during breakup.

Physical Oceanography and Coastal Processes

Also related to minimizing impacts to wetlands and other Waters of the United States are design features of the Project's marine components to mitigate effects on coastal processes including longshore sediment transport and alteration of the seabed and shoreline. These include siting and engineering design measures to assure that natural coastal processes, such as coastal erosion, do not affect the integrity of Project facilities. Key mitigation measures relating to physical oceanography and coastal processes, which are described in detail in Section 4.5 of the EMR, include:

- Using LRDD to develop offshore resources without placing drilling structures in marine waters.
- Using a temporary barge-bridge system for module offloading (estimated at 2 to 4 weeks) limits the effects on lagoon circulation and fish passage, and has minimal effects on coastal sediment transport.
- Limiting dredging/screeding for the barge-bridge system and Service Pier to a small area in the vicinity of the Central Pad.
- Limiting permanent structures in marine waters to six vertical piles and four mooring dolphins for the Service Pier, four mooring dolphins for sea lift barge landings, and a small boat launch at the shoreline.
- Locating the sealift bulkhead and approach gravel ramp for the Service Pier above MHW to minimize the effect on sediment transport or deposition.
- Locating East (new part) and West Pads sufficiently back from the coast to avoid impacts from coastal erosion, storm surge, and ice ride-up for the life of the Project.
- Providing slope protection for the Central Pad to protect against storm surge and wave run-up events.

Spill and Leak Prevention and Containment (Pipelines)

The PTEP and in-field gathering lines will be based on state-of-the-art Arctic designs, specifically tailored for the Project. Prevention and leak detection for both pipelines will include the following unless noted as applying to one:

- Facilities to allow running in-line inspection, maintenance, and cleaning tools:
  - The in-line inspection tools (smart pigs) will be used to monitor both internal and external corrosion.
  - The maintenance and cleaning tools will remove sediment from the lines, thereby reducing the potential for corrosion.
  - Internal corrosion will also be monitored through the use of corrosion coupons and Electrical Resistance probes that provide a measure of corrosion rate and activity. The ability to inject a corrosion inhibitor will be provided.
- The pipelines are designed with a wall thickness to withstand damage from incidental bullet strikes from coastal subsistence hunters. Additional wall thickness will be added, where necessary, to meet this criterion.
- External corrosion prevention through use of shop-installed polyurethane foam insulation covered with a roll-formed, interlocked, bonderized sheet metal jacket. This insulation jacket system has a proven North Slope track record of preventing moisture ingress, which can lead to external corrosion. The pipeline will be shop FBE coated and field joints will be coated with field-applied coating, insulation, sealing, and jacketing to coincide with best available North Slope practices.
- The use of two half-shell, pre-formed weld pack field joints with a small channel for water draining to minimize corrosion under insulation.
- Pipeline hydrostatic testing to verify pipeline integrity in accordance with 49 CFR 195 and American Society of Mechanical Engineers B31.8 for the PTEP and gathering lines, respectively.
- Visual inspections of the pipelines will typically be conducted weekly during operations via aerial surveillance, unless precluded by safety or weather conditions.
- Isolation valves at PTEP inlet at the CPF and at PTEP outlet at Badami to allow rapid shut-in in the event of a leak or rupture.
- Use of vertical loops on either side of East Badami Creek (the only significant stream crossing on the pipeline route) to limit the amount of liquid hydrocarbon that could be spilled in the event of a pipeline leak or rupture. The vertical loops eliminate the need for valve pads on either side of the creeks, thus minimizing gravel placement and possible leak sources (valves).
- An additional wall-thickness for corrosion allowance in the PTEP.
- Internal corrosion of the PTEP will be controlled by dehydration of the liquid hydrocarbon product and injection of corrosion inhibitors, as needed.

- The gathering lines will be constructed of corrosion resistant alloy steel.
- Two independent leak detection systems will be installed on the PTEP. The primary system will meet ADEC's requirement to detect a leak as small as 1 percent of the daily flow rate. This system will use meters on the inlet and outlet of the PTEP, with a state-of-the-art computational system that will perform real-time monitoring for pipeline leaks and will be continually updated via a supervisory control and data acquisition system. An ExxonMobil proprietary leak detection system using different technology will provide another level of protection.

The Project's Execution Plan and Operational Design Minimize Wetlands Footprint

Logistics and Execution

Two important elements of the Project make a substantial contribution to minimizing wetlands footprint:

1. A logistics plan based on a multi-modal transportation strategy, and
2. An efficient execution plan that reduces on-site labor and construction activities. The benefits of this approach, and the consequences of failing to optimize logistics, are demonstrated in detail in the Practicability Analysis (May 13, 2011).

Use of a multi-modal transportation strategy for logistical support has several direct environmental benefits in minimizing wetlands footprint. These include reducing the amount of on-pad storage space required for construction and operations. Reduction in on-pad storage equates directly to reduced pad size and reduced wetlands footprint. This benefit can be achieved because bulk supplies and equipment can be delivered by both barging (summer) and ice road (winter) thus obviating the need to have, for example, more than eight months of supplies on site if an access ice road from the Prudhoe Bay infrastructure is the sole means of such logistical support.

A similar benefit is achieved by minimizing the need for on-site manpower, camps and related support. For example, the use of sealift barges allows large modules to be delivered to Point Thomson directly from the fabrication sites outside of Alaska. The onsite labor hours to install, hookup, and commission the modules are significantly less than would be necessary for the more numerous and smaller modules required if only ice road transport is available to transport those modules to Point Thomson. The significant reduction in on site labor hours translates to smaller accommodation needs and in turn less pad space for those construction camps and related support infrastructure.

Another strategic driver of the Project's execution plan is to schedule activities to avoid significant manpower peaks thus again reducing camp space and related support infrastructure requirements. Use of the multi-modal transportation logistics support strategy also allows a year-round construction schedule that supports the goal of

minimizing construction labor peaks. Again, this translates in smaller pads and less wetland fill.

In contrast, restricting any available means of access would not only result in greater reliance on others, but further constrain already limited seasonal operating windows. This would amplify the intensity and timing of Project logistics requirements such as for fuel, equipment, manpower loading, and water use. In such circumstances there is a risk that certain construction requirements or activities could extend into the following year. Because Project execution involves a carefully coordinated sequence of activities that changes each construction year, an extension of any part of the overall plan could require multi-season ice pads to accommodate the additional scope of activities the following year.

Project Operations

In addition to coastal barging and ice roads, long-term access to the Project will also be supported by an airstrip and by infield roads to the remote drilling pads. These additional wetlands impacts are the minimum necessary to maintain practicable logistics and dependable year round access to the Project from the outside world, and within the Project to the remote drilling pads. This access is essential for long-term operations at a remote site with isolated pads on the North Slope of Alaska which is more than 40 miles from the nearest year-round road connected to major oil field infrastructure and other parts of Alaska.

The airstrip will provide instrument landing capability with very significantly increased access during periods of poor weather. The airstrip will accommodate larger planes for personnel and cargo, substantially reducing the number of flights needed for personnel. It will also accommodate C-130 civilian equivalent size planes, while providing essential means of expeditious access for heavy equipment, supplies and expert support in the event of an emergency response.

Infield gravel roads are essential to provide year round access to the drilling pads. Without these roads, access would be limited to inefficient tundra travel, seasonal ice roads, and helicopter flights subject to weather restrictions. This limited access would constrain logistics, maintenance, inspection, emergency response, and personnel transportation at the remote pads. There is no precedent for imposing such restricted access to drilling pads at any development on the North Slope, especially at a site as remote from other infrastructure as Point Thomson[13].

Because of the importance of year round access to the Project and to the remote pads, it is not practicable to further minimize wetlands footprint by eliminating a full access airstrip and in-field roads. Nevertheless, such restrictions would also result in other significant adverse environmental effects.

[13] ConocoPhillips Alpine CD-3 pad has no year-round road, but has an airstrip for fixed-wing aircraft access and is supplied by a diesel fuel line.

Limiting the size of the airstrip would, as a consequence, require many more flights by much smaller planes while compromising logistics and emergency response access. Eliminating infield road access to the East and West Pads would limit access to the winter season, again compromising logistics and emergency response access, and require construction of several miles of ice road every year for the projected 30-year life of the Project. This would significantly increase water requirements, in turn requiring additional ice road construction for access to remote water sources, and raise potential for tundra impacts. It would also increase impacts resulting from yearly construction activities, including noise and emissions, while requiring annual availability and support for additional personnel and heavy equipment. It would also greatly increase the number of helicopter flights, with much higher fuel use, air emissions, and noise over the Project life. By comparison, such impacts for the long-term operation of the infield gravel roads would be significantly lower. This is illustrated in Figure 69 - Comparison of Infield Transportation Fuel Usage for Construction, Maintenance and Operations - Alternative E's Infield Ice Roads vs. Alternative B's Infield Gravel Roads).

Compensation for Unavoidable Impacts to Waters of the United States, Including Wetlands

Please describe your proposed compensatory mitigation to offset unavoidable impacts to Waters of the United States, or, alternatively, why compensatory mitigation is not appropriate or practicable for your project. Compensatory mitigation involves actions taken to offset unavoidable adverse impacts to Waters of the United States, including wetlands, streams, and other aquatic resources (aquatic sites) authorized by USACE permits. Compensatory mitigation may involve the restoration, enhancement, establishment (creation), and/or the preservation of aquatic sites. The three mechanisms for providing compensatory mitigation are mitigation banks, in-lieu fee of mitigation, and permittee-responsible mitigation. Please see the attached definitions for additional information.

Regulatory Context of Implementing Compensatory Mitigation in Alaska

Introduction and Summary of ExxonMobil Proposal

ExxonMobil has made significant efforts to avoid and minimize impacts to aquatic resources including North Slope tundra wetlands. These efforts are summarized above and documented in detail in the attached *Point Thomson Project Environmental Mitigation Report* (Appendix A). Nevertheless, certain unavoidable impacts to wetlands will remain.

The following mitigation proposal, with USACE input and approval, is intended to lead to development of a detailed Mitigation Plan to provide appropriate and practicable compensation for such unavoidable impacts. Regulatory guidance provides that this initial mitigation statement should be brief, because it occurs in the early stages of the evaluation process.

After considerable research on compensatory mitigation options and opportunities available in Alaska, documented below, ExxonMobil has concluded that the only viable option for the Point Thomson Project is through The Conservation Fund's (TCF) in-lieu fee program. ExxonMobil proposes to utilize this program, either as approved subject to currently pending revision and updating, or as presently in place (grandfathered) in 2011[14].

The documentation below summarizes the compensatory mitigation options available under the 2008 regulations, the availability in Alaska of those options, and the regulatory context related to the application of compensatory mitigation in Alaska which presents unique problems and challenges to its implementation in this State.

Regulatory Background and Compensatory Mitigation Options

Compensatory mitigation is addressed by the 404(b) Guidelines and by specific regulations at 33 CFR 332 seq. These regulations were amended in 2008, and now establish new pre-approval procedures and standards for mitigation programs. Current programs are subject to a maximum potential five-year period to meet these new requirements.

The regulations also establish new preferences for both the providers and types of mitigation. At the same time, the regulations continue to recognize the need for flexibility in the application of mitigation requirements to address regional and local circumstances. As will be seen, the most notable example of this is Alaska.

The regulations as revised in 2008 recognize three potential forms of mitigation, with the following order of preference: (1) use of an approved mitigation bank; (2) use of an approved in-lieu fee program; (3) permittee-responsible mitigation.

Summary of Mitigation Options

USACE has summarized the above mitigation options as follows[15].

> Compensatory mitigation is typically accomplished through the following three ways:
>
> 1. Mitigation Banks: A permit applicant may obtain credits from a mitigation bank. A mitigation bank is a wetland, stream or other aquatic resource area that has been restored, established, enhanced or

[14] At the time of completion of this application (mid-October, 2011) the Conservation Fund's prospectus has been issued for a 30-day public comment period which commenced September 29, 2011. That proposal has been prepared pursuant to amended USACE and U.S. Environmental Protection Agency (EPA) regulations at 33 CFR 332. ExxonMobil will monitor the progress of the approval process of that proposal and implementing instruments particularly with respect to the timing of the 404 permitting process. ExxonMobil's detailed Mitigation Plan will be developed based upon and reflecting the most current approved TCF program.

[15] *Compensatory Mitigation Rule: Improving, Restoring, and Protecting the Nation's Wetlands and Streams* (http://www.epa.gov/owow/wetlands/pdf/Mit_rule_QA.pdf)

preserved. This resource area is then set aside to compensate for future impacts to aquatic resources resulting from permitted activities. The value of a bank is determined by quantifying the aquatic resource functions restored, established, enhanced and/or preserved in terms of "credits." Permittees, upon approval of regulatory agencies, can acquire these credits to meet their requirements for compensatory mitigation.

2. In-Lieu Fee Mitigation: A permit applicant may make a payment to an in-lieu fee program that will conduct wetland, stream or other aquatic resource restoration, creation, enhancement, or preservation activities. In-lieu fee programs are generally administered by government agencies or non-profit organizations that have established an agreement with the regulatory agencies to use in-lieu fee payments collected from permit applicants.
3. Permittee-Responsible Mitigation: A permittee may be required to provide compensatory mitigation through an aquatic resource restoration, establishment, enhancement and/or preservation activity. This compensatory mitigation may be provided at or adjacent to the impact site (i.e., on-site mitigation) or at another location, usually within the same watershed as the permitted impact (i.e., off-site mitigation). The permittee retains responsibility for the implementation and success of the mitigation project.

Mitigation banks and in-lieu fee mitigation are forms of "third-party" compensation because a third party, the bank or in-lieu fee sponsor, assumes responsibility from the permittee for the implementation and success of the compensatory mitigation.

Mitigation in the Unique Circumstances of Alaska

In considering an appropriate approach to mitigation for Point Thomson it must also be recognized—as the Environmental Protection Agency (EPA), USACE, and the regulations have—that application of requirements for mitigation in Alaska may call for flexibility in light of the unique circumstances of wetlands in this state. These include extensive contiguous wetlands (minimally impacted by development), extensive areas of publicly owned land (many in federal or state conservation status) and few opportunities

for rehabilitation or restoration of damaged wetlands[16]. This is particularly true of the arctic foothills and coastal plain, where according to USACE up to 83% of the land is wetlands[17].

In the *Alaska Wetlands Initi*ative, USACE, EPA[18] and other agencies considered the special circumstances of Alaska with respect to wetlands and national policy, and issued guidance on the applicable regulatory flexibility in two attachments. Relevant conclusions include the following:

A. Avoiding wetlands may not be practicable where there is a high proportion of land in a watershed or region which is wetlands; and

B. Restoring, enhancing, or creating wetlands through compensatory mitigation may not be practicable due to limited availability of sites or technical/logistical limitations.

The continued application of these statements in the *Alaska Wetlands Initiative* was specifically endorsed by USACE and the United States Environmental Protection Agency (EPA) in adopting the 2008 compensatory mitigation regulations. Compensatory Mitigation Final Rule, 73 Federal Register (FR) 19619 (April 10, 2008).

ExxonMobil believes it will be appropriate to consider these circumstances in assessing the specific mitigation plan discussed below.

---

[16] Alaska is estimated to have approximately 175,000,000 acres of wetlands, comprising approximately 43% of the surface area of the State: By comparison, the remainder of the U.S. contains approximately 103,000,000 acres of wetlands, comprising approximately 5% of the surface area.' In addition, much of Alaska's non-wetlands area consists of mountainous areas or more remote interior regions. Over one half of Alaska is Federally owned in National Wildlife Refuges, National Parks, National Forests, National Petroleum Reserve lands, and other designations. The State owns approximately 30%, Alaska Native Corporations own approximately 12%, and less than one percent is otherwise privately owned. Recent estimates indicate that approximately 66% of the States wetlands are found within Federally managed land, approximately 23% within State lands, approximately 11% under Native ownership, and less than 1% otherwise privately owned."

-- Alaska Wetlands Initiative Summary Report, U.S. Environmental Protection Agency, Department Of The Army, U.S. Fish And Wildlife Service, National Marine Fisheries Service (NOAA), May 13, 1994, at pages 2-3.

[17] U.S. Army Corps of Engineers, Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Alaska Region (Version 2.0) September 2007, at page 5.

[18] In a concurrent notice, concluding that no special rule for Alaska was needed, EPA separately stated: "EPA believes that the definition of "practicable" affords discretion and flexibility to the Corps to craft case-specific decisions that effectively consider highly diverse environmental, economic, and geographical conditions, including those found in Alaska." EPA, Exception from Mitigation Sequence for Alaska, May 19, 1994.

ExxonMobil Research into the Availability of Compensatory Mitigation Options

Mitigation Banks -- ExxonMobil's research indicates there are no established mitigation banks in Alaska with specific service areas north of Anchorage or the Matanuska-Susitna areas. This research included contacts with in-lieu fee program sponsors, the NSB, Arctic Slope Regional Corporation (ASRC) (the largest owner of non-public lands on the North Slope), and other oil companies operating on the North Slope that have been subject to compensatory mitigation requirements in order to obtain Section 404 permits.

No mitigation bank is therefore currently approved with a service area, which includes the Project area or the North Slope of Alaska. (See the USACE Alaska District website, "Alaska District Approved Mitigation Banks," listing only three banks with service areas limited respectively to small areas of Anchorage, Southcentral Alaska, and Southeast Alaska)[19]. In addition, ExxonMobil is not aware of any plans underway by public or private organizations to establish mitigation banks on the North Slope.

It must also be appreciated that mitigation banks are private enterprises, which require sponsors, capital, and organization. Mitigation banks must also be approved by USACE following federal interagency review, and must have mitigation sites identified in advance of providing mitigation in a specific instance. In light of all these requirements, even if organization of a new bank with a service area including the North Slope were feasible and undertaken immediately, there is insufficient time available until Project permitting and start-up in winter season 2015-16 for use here.

In-Lieu Fee Programs -- ExxonMobil identified several in-lieu fee programs and land trust providers in the State including TCF, Great Land Trust, Kachemak Heritage Land Trust, and Interior Alaska Land Trust. Only TCF has an authorized service area which includes the entire State (and thus the Project area) [see the USACE Alaska District website, "Alaska District In-Lieu Fee Sponsors"[20]]. TCF is also apparently the only program with a proposal before USACE and Interagency Review Team (IRT) for approval of a revised program to conform to the 2008 regulations. ExxonMobil understands that this proposal will for the first time establish a service area specific to Arctic Alaska, including the North Slope. As a result, ExxonMobil held several meetings with a representative of TCF to find out more about the organization and its program, and to assess the potential to use its in-lieu fee program for compensatory mitigation.

TCF has been an approved provider of compensatory mitigation in Alaska since 1998. While TCF has been authorized to continue to operate under its existing program, the Fund is also currently engaged in updating its program to conform to USACE and EPA

20 http://www.poa.usace.army.mil/reg/links/Alaska%20District%20In-lieu%20Fee%20Sponsors.pdf

2008 regulations at 33 CFR 332 et seq. It is understood that the new program will include a service area encompassing the North Slope and the Project area, and contain a compensation-planning framework providing more specific procedures for providing mitigation in this region.

Based on these discussions and information provided by TCF, the following positive attributes of their organization and program were evident:

- Statewide program approved by USACE and grandfathered through mid-2011 (with the potential for further program extension depending upon the status of approval of its revised proposal before the USACE);
- A proposal currently before the USACE and IRT for approval of a revised program to comply with the 2008 regulations including division of the state into five service areas (Footnote 14);
- A proven track record of implementing conservation projects in Alaska (operating in the State since 1994) and in many other regions of the U.S. including providing compensatory mitigation;
- Provision of services for compensatory mitigation for several North Slope oil and gas operators including BP and ConocoPhillips;
- Participation in conservation projects with federal and state agencies and native organizations; and
- A high rating by evaluators of non-governmental organizations (NGOs).

Permittee-responsible Mitigation -- In lieu-fee programs are preferred over permittee-responsible mitigation by USACE: "[I]n-lieu fee programs have certain advantages over permittee-responsible mitigation. They generally involve larger parcels, have access to appropriate scientific and technical expertise, may have a proven track record in establishing successful mitigation in the past, and will generally have a more fully developed watershed approach, developed through their required comprehensive planning framework." Compensatory Mitigation Final Rule, 73 FR 19613 (April 10, 2008). Conversely, direct provision of mitigation is outside the core areas of business, technical expertise, and organizational structure of a permittee for a project in an unrelated field such as development of an oil and gas project.

Potential Mitigation Opportunities on the North Slope

ExxonMobil reviewed USACE and oil industry databases regarding North Slope gravel fill, use, site histories, ownership, and permit status. Based on that information it appears that opportunities are very limited and unlikely to yield any significant restorable acreage particularly given the Project's larger unavoidable wetlands impacts and possible compensation ratios to be applied. Most of the gravel fill for oil development projects is still in use, and in any event, remains for the most part the legal responsibility of other companies under existing permits. Significant practicability issues would also be presented.

In addition, a meeting was held with representatives of the NSB regarding possible NSB efforts to establish mitigation banks and how the NSB was addressing compensatory mitigation for its projects. Only one relevant project was identified that involved establishment of a conservation easement related to compensation of wetlands fill in the Deadhorse area. The NSB has identified approximately 8,000 acres of land from the State of Alaska as part of its municipal land entitlement. These lands are located in a number of tracts on the North Slope between the Colville and Sagavanirktok Rivers. Most of these lands were selected for economic or resource (gravel mining) development potential. Two tracts - one south of the Kuparuk oil field (Meltwater East) and the other adjacent to the Kuparuk River in the Prudhoe Bay oil field have been identified as having potential use as conservation easements. However, the ADNR has yet to approve these land selections.

A meeting was also held with ASRC to see if consideration had been given to using some of its lands for conservation purposes. Several years ago, there had been some discussions between ASRC and the U.S. Department of Interior Bureau of Land Management relating to possible land trades for conservation purposes but such trades did not mature. ASRC may be interested in using some of its lands for conservation purposes. ExxonMobil was advised that there might be native allotment owners who would be interested in the establishment of conservation easements on their lands.

The results of the above discussions indicate there may potentially be opportunities for providers such as TCF to pursue mitigation on the North Slope. However, it would be premature to predict whether these can be realized in a given instance or in a predictable timeframe.

ExxonMobil's Wetlands Evaluations

An integral part of ExxonMobil's development of wetlands mitigation measures and support for the EIS and Section 404 permitting processes has been wetlands/vegetation mapping. Table 3 provides information on vegetation types affected by the Project's gravel fill. In addition, ExxonMobil is submitting a Preliminary Jurisdictional Determination to USACE along with this application to assist DA in processing this permit.

To be submitted under separate cover, ExxonMobil has prepared a preliminary value and categorization of the wetland functions affected by the Project. The rating of these values has been proposed in conformance with USACE guidelines. ExxonMobil will submit these to USACE for its review and determination of the appropriate ratings prior to implementing the mitigation plan as described in the next section. Importantly, there is consistency between this categorization and the wetlands functional assessment developed by the third party contractor for the Project EIS because ExxonMobil had input into the development of the EIS assessment methodology and used the output from that assessment as the basis for the categorization.

ExxonMobil's Proposal and Commitment

As documented above, ExxonMobil has made a significant effort to research opportunities for compensatory mitigation and conducted interviews with potential stakeholders who may be able to facilitate mitigation. This research indicates that the only viable option for compensatory mitigation available in the timeframe needed for the Project is the Conservation TCF's in-lieu fee program. ExxonMobil proposes to utilize either the program currently (Spring 2011) in place (grandfathered) or the program revised to conform to the 2008 regulations currently pending approval by the USACE.

ExxonMobil anticipates that, subject to agency review and public comment, TCF will secure USACE approval of a new program and conservation plan in the next few months. The Fund instrument is expected to specify procedures for provision of compensation in service areas within Alaska, including the North Slope, in conformance with the 2008 regulations. This new program instrument will help inform the appropriate and practicable approach to a Mitigation Plan for the Project. In the event that TCF's prospectus is not approved in time of permit decision-making and issuance, ExxonMobil would utilize the program currently in place (grandfathered).

In utilizing this program, ExxonMobil commits to be an active participant in the mitigation assessment and make its best efforts during the Section 404 permitting process to assure that suitable lands will be conserved as a result of compensatory mitigation payments for the Project. (This goes above the strict requirements of an applicant's role as specified in the 2008 regulations and demonstrates ExxonMobil's good faith desire to demonstrate environmental performance on the North Slope.) This commitment includes:

- Provision of assistance and facilitation to TCF in identifying potential North Slope wetlands for conservation;
- Participation in discussions between TCF and potential North Slope land owners (e.g., North Slope native corporations) who may wish to sell land or place lands in conservation easement status; and
- Assistance to TCF in the evaluation of candidate wetlands (classification, functions, values) including provision of technical services of wetland scientists.

Through this active participation, ExxonMobil hopes to facilitate potential acquisition by the Fund of North Slope tundra wetlands for conservation purposes and expedite such land purchases once in-lieu fee payment has been made. However, there are no guarantees that similar (in-kind) North Slope tundra wetlands will be available. Subject to USACE approval, the responsibility for determination of available and appropriate mitigation sites will rest with the Fund, which (unlike ExxonMobil) has longstanding expertise in identifying and establishing mitigation sites in Alaska.

TAB 26: REGULATORY APPROVALS

This section summarizes the regulatory approvals and authorizations applicable to the Project. Table 6A provides an overview of the several agencies with Project jurisdiction and their respective regulatory programs. Many of these are underway and in various stages of completion including the EIS, the DA permit, Section 106 National Historic Preservation Act (NHPA) consultation, Section 7 Endangered Species Act (ESA) Consultation, the prevention of significant deterioration (PSD) air permit, and the PTEP ROW Lease.

Table 6B contains information about the status of specific permits which were obtained for the 2009-2010 Point Thomson drilling program. Some of these are currently in effect and would be used by the Project; others are representative of permits that will be obtained for the Project.

TABLE 6A: KEY REGULATORY ACTIONS

Regulatory Action	Agency	Applicability
Federal		
NEPA Review/Environmental Impact Statement	USACE; Lead NEPA Agency	Review of environmental impacts of the entire Project, including construction and operations.
DA Permit Section 404/10	USACE	Placement of fill onto U.S. waters, including wetlands, and structures in navigable waters.
Letters of Authorization (LOAs) for Incidental Take of Marine Mammals (Polar Bear and Pacific Walrus)	U.S. Fish and Wildlife Service (USFWS), Marine Mammal Section	Annual LOAs for construction and operations.
Section 7 ESA Consultation	USFWS	Consultation for spectacled eider, Steller's eider, and polar bears for the Project.
Section 7 ESA Consultation	National Marine Fisheries Service (NMFS)	Consultation for bowhead whales for the Project.
Essential Fish Habitat Determination	NMFS	Essential Fish Habitat for Project components and activities in marine waters.
NHPA Section 106 Consultation	USACE	Consultation with ADNR State Historic Preservation Office.
Spill Prevention, Control, and Countermeasure Plan	EPA	For construction, drilling, and operations.
Facility Response Plans	EPA, U.S. Department of Transportation (DOT), U.S. Coast Guard (USCG)	For construction, drilling, and operations.
Underground Injection Control	EPA	Class I disposal well.
NPDES General Permit [1]	EPA	Regulated discharges to Waters of the United States.
State		
Plan of Development and Operation	ADNR, Division of Oil and Gas	For Project development and IPS operations.
Air Quality Control (PSD) for Construction	ADEC	Air emissions – construction.

Regulatory Action	Agency	Applicability
Title V Air Permit for Operations	ADEC	Air emissions – operations.
Alaska Pollutant Discharge Elimination System (APDES) Permit[1]	ADEC	Regulated discharge to Waters of the United States.
Temporary Storage of Drilling Waste	ADEC	Waste management.
PTEP Right-of-Way Lease[2]	ADNR, SPCO	Export Pipeline construction, operations, and termination in ROW on state land.
Oil Discharge Prevention and Contingency Plan	ADEC	Drilling and operations.
CWA Section 401 Certification	ADEC	Reasonable assurance that applicable water quality standards will be met (required for DA permit).
Land Use Permits	ADNR, Division of Mining, Land, and Water (DMLW)	Miscellaneous land use (e.g., ice roads).
Temporary Water Use Permits	ADNR, DMLW	Water use for ice roads, drilling, domestic, and construction activities.
Material Sales Contract	ADNR, DMLW	Gravel mining and mine site rehabilitation.
OHA Clearance	ADNR, Office of History and Archaeology (OHA)	Clearance prior to commencing construction.
Title 16 Fish Habitat Permits	Alaska Department of Fish and Game (ADF&G)	Mine site development, water withdrawal, and stream crossings.
Local		
Master Plan, Re-zoning and Development Permits (Title 19)	NSB	For construction and operations within the NSB.
Inupiat History, Language, and Culture (IHLC) Certificate	NSB	Traditional Land Use Inventory (TLUI) clearance prior to commencing construction.

[1] – This listing assumes that the EPA NPDES General Permit AKG-33-0000 will be in effect. Individual APDES permit applications for camp wastewater discharges will be submitted to ADEC. ADEC may issue authorization under a General Permit, if available.
[2] – The Point Thomson Export Pipeline will be authorized under a Pipeline Right-of-Way Lease, issued by the SPCO, under AS 38.35.

Key:
ADF&G – Alaska Department of Fish and Game
APDES – Alaska Pollutant Discharge Elimination System
AS – Alaska Statute
DMLW – Division of Mining, Land, and Water (ADNR)
DOT – U.S. Department of Transportation
IHLC – Inupiat History, Language, and Culture
LOA – Letter of Authorization
NMFS – National Marine Fisheries Service
NPDES – National Pollutant Discharge Elimination System
OHA – Office of History and Archaeology (ADNR)
TLUI –Traditional Land Use Inventory
USCG – U.S. Coast Guard
USFWS – U.S. Fish and Wildlife Service

FIGURES

Map features presented here are derived from photogrammetric mapping, site surveys, and civil engineering data. Features are displayed using the Alaska State Plane Coordinate System, Zone 3 projection and North American Datum 1983 (NAD83) datum. Elevation information is based on vertical tidal datum of MLLW. Use National Tidal Datum Epoch 1983-2001, Prudhoe Bay, AK for transformations to other known vertical datums.

The following is a list of the figures presented in this section and referenced throughout the body of the Application.

Re: Point Thomson Project Environmental Mitigation Report

Exxon Mobil Corporation (ExxonMobil) is pleased to submit the *Point Thomson Project (PTP) Environmental Mitigation Report* (EMR). This report provides an overview of the mitigation measures that are incorporated into the engineering design, construction, and operation plans of the Project. This EMR is intended to support the NEPA review of the proposed Project (EIS Alternative B) and to assist the U.S. Army Corps of Engineers (USACE) and Cooperating Agencies in identifying appropriate mitigation measures in the draft and final EIS and Section 404 permits. This EMR is also intended to provide supporting information for other permits, as appropriate.

As detailed in the EMR, addressing environmental performance has been an integral consideration in the design, engineering and planning of the PTP. The EMR therefore includes an explanation of the project's engineering design and supporting studies and information which should provide a well grounded understanding of mitigation.

The EMR is organized to broadly match the organization of the *Point Thomson Project Preliminary Draft EIS* major resource categories to the extent the mitigation measures apply. This EMR does not describe all of the mitigation associated with the Project, but rather focuses on the main measures incorporated to protect the environment and enhance environmental performance. Where applicable, measures described under one resource are cross-referenced to other resources to avoid repetition of the measures, without losing relevance of the mitigation.

As you know, mitigation is of fundamental importance under NEPA. Mitigation is defined in NEPA regulations at §1508.20 to include avoiding, minimizing, rectifying, reducing over time, or compensating for project impacts. The lead and cooperating agencies are required in the NEPA alternatives analysis to address "appropriate mitigation measures not already included in the proposed action or alternatives." §1502.14(f). Similarly, the final Record of Decision must "[s]tate whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted…" §1505.2(c).

Mitigation is equally important under the CWA §404 (b)(1). Guidelines established by the USACE and U.S. Environmental Protection Agency (EPA) set forth a "mitigation sequence" requiring a demonstration that impacts have been avoided or minimized where avoidance is not possible. Section 404(b)(1) addresses in particular impacts to aquatic resources as required by the CWA, USACE regulations (33 CFR Parts 320-325), and EPA's 404 (b)(1) Guidelines (40 CFR Part 230). This EMR, therefore, specifically describes Project mitigation measures that

avoid or minimize impacts to aquatic resources. Appendix A provides a cross-reference of Project mitigation as it applies to applicable requirements of the §404 (b)(1) Guidelines.

Attached for reference are the Oil Spill Contingency Mitigation Agreement and the 2011 Conflict Avoidance Agreement (CAA). ExxonMobil has also submitted to your office the EIS Cooperating Agencies and HDR (the EIS third party contractor) various technical documents and workshop presentation materials which support this EMR and further document mitigation incorporated into the PTP including:

- Point Thomson Project Hydrology Report, Revision 0 (November 2010)
- Point Thomson Project, 2010 Hydraulics Report, Revision 0 (March 2011)
- Material Site Development and Hydrology Workshop (Gravel Mining and Rehabilitation Plan) (3/15/2011)
- Hydrology Workshop (3/8/2011)
- Ice Roads and Water Use Workshop (4/21/2011)

We would be pleased to address comments and questions on this EMR at a regular or special meeting of the EIS Coordination Team if desired by the Corps and cooperating agencies. If you have any questions, please contact Brien E. Reep at (907) 564-3617 or via email (brien.e.reep@exxonmobil.com) or Steve Calder (907) 564-3787 or via email (steve.calder@exxonmobil.com).

Sincerely,

Brien E. Reep
For and On Behalf of Exxon Mobil Corporation

1.0 INTRODUCTION

Exxon Mobil Corporation (ExxonMobil) is proposing to construct and operate the Point Thomson Project (Project) to delineate and produce hydrocarbon resources in the Point Thomson Unit on the North Slope of Alaska. Produced fluids will be processed on site, with liquids exported by pipeline to existing common carrier pipelines that supply the Trans Alaska Pipeline System (TAPS) and natural gas reinjected into the reservoir. The U.S. Army Corps of Engineers (USACE) is the lead federal agency preparing an Environmental Impact Statement (EIS) for the Project, pursuant to the National Environmental Policy Act (NEPA) 42 United States Code (USC) Section (§) 4321 et seq., and regulations including 40 Code of Federal Regulations (CFR) Parts 1500-1508. The USACE is also responsible for issuance of Clean Water Act (CWA) §404 dredge and fill permits required for the Project.

This Environmental Mitigation Report (EMR) provides an overview of the mitigation measures that are incorporated into the engineering design, construction, and operation plans of the Project. This EMR is intended to support the NEPA review of the proposed Project (EIS Alternative B) and to assist the USACE and Cooperating Agencies in identifying appropriate mitigation measures in the draft and final EIS and Section 404 permits. This EMR is also intended to provide supporting information for other permits, as appropriate.

This EMR is organized to broadly match the organization of the *Point Thomson Project Preliminary Draft EIS* major resource categories to the extent the mitigation measures apply. This EMR does not describe all of the mitigation associated with the Project, but rather focuses on the main measures incorporated to protect the environment and enhance environmental performance. Where applicable, measures described under one resource are cross-referenced to other resources to avoid repetition of the measures, without losing relevance of the mitigation.

Mitigation is of fundamental importance under NEPA. Mitigation is defined in NEPA regulations at §1508.20 to include avoiding, minimizing, rectifying, reducing over time, or compensating for project impacts. The Lead and Cooperating Agencies are required in the NEPA alternatives analysis to address **"**appropriate mitigation measures not already included in the proposed action or alternatives." §1502.14(f). Similarly, the final Record of Decision must "[s]tate whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted…" §1505.2(c).

Mitigation is equally important under the CWA §404 (b)(1). Guidelines established by the USACE and U.S. Environmental Protection Agency (EPA) set forth a "mitigation sequence" requiring a demonstration that impacts have been avoided or minimized where avoidance is not possible. Appropriate compensatory mitigation will be provided for unavoidable impact. Such compensatory mitigation will be addressed in ExxonMobil's Section 404 permit applications.

CWA §404(b)(1) addresses, in particular, impacts to aquatic resources as required by the CWA, USACE regulations (33 CFR Parts 320-325), and EPA's 404 (b)(1) Guidelines (40 CFR Part 230). This EMR, therefore, specifically describes Project mitigation measures that avoid or minimize impacts to aquatic resources. **Appendix A** provides a cross-reference of Project mitigation to applicable requirements of the §404 (b)(1) Guidelines.

For both the NEPA analysis and Section 404 permitting decisions, it is essential that the USACE and Cooperating Agencies be fully apprised of, and the public record reflect, the baseline of mitigation measures that have been developed for, or will be applicable to, the Project. As the recently adopted Council on Environmental Quality guidance on mitigation recognizes (January

11, 2011, Section 1.A, Page 5), this should first include “mitigation incorporated into project design.” This EMR, therefore, summarizes the specific design, engineering, construction, and other mitigation measures developed for, or incorporated into, the Project.

For the Project, ExxonMobil has developed several innovative measures to reduce environmental and subsistence impacts and meet regulatory requirements. For example, to avoid the need for a solid-fill causeway for module offloading, ExxonMobil engineered a temporary “barge-bridge” system. In addition, ExxonMobil developed a state-of-the-art polar bear interaction program reflecting significant new mitigation measures that were incorporated into the Letters of Authorization for Incidental Take (LOA) issued by the U.S. Fish and Wildlife Service (USFWS). ExxonMobil also developed numerous affirmative measures to avoid or minimize effects on subsistence, and established a collaborative relationship with local communities and organizations to ensure continuing protection of subsistence resources and activities. ExxonMobil established, and will continue to support, a community outreach program to keep the North Slope Borough (NSB), particularly Kaktovik residents, informed of Project activities, and provide opportunities to discuss related topics and mutually develop solution-oriented actions.

The baseline of mitigation measures incorporated into the Project planning and design includes numerous, proven North Slope best management practices (BMPs) developed over more than 40 years of experience with North Slope drilling and production projects such as at Prudhoe Bay and Point Thomson. Based on their proven effectiveness, many of these BMPs have evolved over time into state and local permit conditions and comprise an integral part of the mitigation in place for the Project. This EMR includes some agency-standardized practices that also reflect elements of the proposed Project, but does not address the full range of mitigation that will be in place. It is expected that many standardized mitigation measures will be incorporated into permits issued for the Project, with additional Project-specific mitigation required, as appropriate[1].

Additional information describing the project mitigation was provided during the following EIS workshops provided for the USACE, cooperating agencies, and third-party EIS consultant:

- Hydrology Workshop (3/8/2011)
- Material Site Development and Hydrology Workshop (Gravel Mining and Rehabilitation Plan – 3/15/2011)
- Ice Roads and Water Use Workshop (4/21/2011)

ExxonMobil has over 90 years of Arctic and subarctic experience. In 1920, ExxonMobil discovered the Norman Wells oilfield located just south of the Arctic Circle on the shores of the Mackenzie River in Canada’s Northwest Territories. This oilfield was brought into commercial production in 1932, and is still the most northerly producing oilfield in Canada. ExxonMobil’s first commercial discovery in Alaska was the Granite Point field in Cook Inlet in 1965, which was

[1] The recently concluded 2008-2011 Point Thomson drilling program was conducted pursuant to more than 50 federal, state, and North Slope Borough permits that collectively contained literally hundreds of environmental stipulations and conditions. Because many of the activities of the drilling program will also be conducted for Project construction and operation (e.g., ice road construction, polar bear interaction mitigation measures, water use, etc.), it is expected that many of the same or very similar permits and conditions will also apply to the Point Thomson Project. A summary of related government agency and associated permit and regulatory requirements is provided to the public at: http://www.dog.dnr.alaska.gov/products/publications/beaufortsea/bsaw2009_final_finding/beaufort_sea_final_finding.html.

brought into commercial production in 1967**.** ExxonMobil and Atlantic Richfield were each 50 percent owners (partners) in the Prudhoe Bay discovery well, and ExxonMobil continues to have a significant role in ongoing field development activities. Most recently in Alaska, ExxonMobil constructed the necessary infrastructure and drilled the PTU-15 and PTU-16 wells at Point Thomson to high environmental performance standards without impacting subsistence. This record and experience directly relates to many mitigation measures that will employed in the proposed Project.

ExxonMobil has a sustained commitment to Arctic technology research and development of more than 35 years, and has industry's only dedicated, in-house oil spill response research program.

For all activities, ExxonMobil strives to continuously improve upon its high safety and environmental performance. This is done through consistent and diligent application of the ExxonMobil Operations Integrity Management System (OIMS), which has been in place for nearly 20 years and is credited with obtaining best in class safety, health, and environmental performance. The corporate environmental initiative **Protect Tomorrow. Today.** directs employees and contractors to seek continuous improvement in environmental protection even where laws and regulations may not exist, These are not just words, but fundamental ExxonMobil principles, management systems, and directives to operate safely, protect the environment, and, where appropriate, go beyond compliance with regulatory standards.[2]

ExxonMobil's industry leadership in safety and environmental protection is widely recognized. For example, according to the New York Times, "By every measure, ExxonMobil has by far the best safety record in the industry." (New York Times, June 18, 2010).[3] In a separate article, the Times stated that, after a "profound rethinking of safety management," "ExxonMobil developed a rigid system of rules for all its operations, from gas stations to offshore platforms, and empowered everyone, even contractors, to speak up about safety problems. Today, Exxon stands out among its peers for its obsessive attention to safety, according to analysts and industry insiders." (New York Times, July 12, 2010).[4]

In a letter to stakeholders, Chairman and Chief Executive Officer (CEO) of ExxonMobil, Rex W. Tillerson, set the clear expectation that:

> *"We will remain committed to safe operations and environmental protection in every aspect of what we do, every day."*

[2] ExxonMobil's activities and commitments in environmental protection and safety are documented in the annual Corporate Citizenship Report (CCR), available to the public at: http://www.exxonmobil.com/Corporate/Imports/ccr2010/community_ccr.aspx.

2.0 CORPORATE ENVIRONMENTAL STEWARDSHIP AND PROGRAMS

ExxonMobil believes that strong environmental performance is integral to overall successful project performance. Key elements of ExxonMobil's corporate environmental stewardship initiatives and programs are described below.

2.1 EXXONMOBIL CORPORATE INITIATIVES

ExxonMobil's corporate Environment Policy states:

> *"It is our policy to conduct our business in a manner that is compatible with the balanced environmental and economic needs of the communities in which we operate. We are committed to continuous efforts to improve environmental performance throughout our operations worldwide."*

In response to the Corporate Policy, the Project adopted the goal to "Be the Standard for Arctic Environmental Excellence." To achieve this goal, two key corporate initiatives are being applied to the Project:

- OIMS
- **Protect Tomorrow. Today.**

2.1.1 Operations Integrity Management System

ExxonMobil introduced OIMS in 1992. It provides a set of expectations embedded into everyday work processes at all levels of the organization and addresses all aspects of managing safety, health, security, environmental, and social risks at ExxonMobil's facilities worldwide. It is designed to identify hazards and manage risks inherent to operations and associated with the full life cycle of projects. Key elements of OIMS are:

- **Management Leadership, Commitment, and Accountability:** specific roles and accountabilities.
- **Risk Assessment and Management:** Ongoing risk management.
- **Facilities Design and Construction:** Standards and practices.
- **Information and Documentation:** Drawings and other required documentation.
- **Personnel and Training:** Skill maintenance, safety, and health management.
- **Operations and Maintenance:** Procedures, programs including regulatory compliance.
- **Management of Change:** Permanent and temporary changes.
- **Third-Party Services:** Contractor management.
- **Incident Investigation and Analysis:** Root cause identification and global sharing.
- **Community Awareness and Emergency Preparedness:** Response planning and drills.
- **Operations Integrity Assessment and Improvement:** Ongoing audit and findings resolution.

The overall effectiveness of OIMS is reviewed periodically and enhanced accordingly. As a result, OIMS has gradually evolved to enhance behavior-based safety, leadership, security, environmental aspects, and community involvement. Lloyd's Register Quality Assurance, Inc. (LRQA) has reviewed ExxonMobil's ongoing performance and has attested that OIMS meets the requirements of the standard for environmental management systems (International Organization for Standardization [ISO] 14001:2004) and the Occupational Health and Safety Assessment Series (OHSAS) for health and safety management systems (OHSAS 18001:2007).

2.1.2 Protect Tomorrow. Today.

Protect Tomorrow. Today. is a management-driven corporate initiative providing guidance on environmental expectations with the goal of continual improvement in environmental performance. ExxonMobil wants to achieve excellent environmental performance and be recognized as an industry leader who operates responsibly everywhere it does business and that, in doing so, will **Protect Tomorrow. Today.**

ExxonMobil is committed to operating responsibly everywhere we do business by implementing scientifically sound, practical solutions to meet energy needs in an environmentally responsible manner. It is a long-standing policy to conduct business in a manner that is compatible with the balanced environmental and economic needs of the communities in which ExxonMobil operates.

ExxonMobil seeks to drive incidents with real environmental impact to zero, and to operate in a manner that is protective of the environment. ExxonMobil is committed to continuous efforts to improve environmental performance throughout our operations.

2.2 PROJECT ENVIRONMENTAL AND SAFETY TRAINING PROGRAM

The Project has a robust training system in place in order to ensure employee safety, regulatory compliance, and excellent environmental performance. General environmental, socioeconomic, and regulatory awareness training is planned for employee and contractor personnel assigned to the North Slope. This training must be completed prior to arrival on the North Slope. Additional training will be provided, depending on the requirements of an individual's work assignment and the work to be performed. ExxonMobil has developed the "Arctic Pass" training process that addresses the induction and ongoing training necessary for ensuring that ExxonMobil North Slope-based project workers will have the appropriate orientation and training.

The Project's training system covers different levels, from new worker orientation to periodic refreshers for experienced workers. The two primary components of this training program include the North Slope Training Cooperative (NSTC) Unescorted program and the Arctic Pass training. Both programs ensure that Project personnel are aware of applicable regulatory approval conditions and requirements, as well as safety, health, environmental, socioeconomic, and security expectations and requirements related to working on the North Slope. The NSTC training was developed by other operators on the North Slope. It is a 1-day training seminar that is mandatory for all personnel working in, and unescorted visitors to, any operating field on the North Slope. Arctic Pass training was developed by ExxonMobil specifically for this Project and covers topics above and beyond NSTC training.

Arctic Pass training includes components related to environmental and cultural awareness, permit and regulatory compliance, wildlife interaction, the Oil Discharge Prevention and

Contingency Plan (ODPCP), and compliance with ExxonMobil and other applicable industry expectations. Components of the training program include, but are not limited to:

- Site Orientation
- Regulatory Compliance
- Alaska Native Cultural Awareness
- Driving/Road Rules
- Winter Driving/Ice Road Rules
- Environmental Awareness
- Waste Management
- Spill Prevention and Reporting
- Polar Bear and Wildlife Interaction
- Job Safety Analysis
- Eye, Hand, and Back Safety
- Behavior Based Safety Processes
- Food Safety
- Arctic Water Survival
- First Aid/Cardiopulmonary Resuscitation/Automated External Defibrillator.

2.3 ENVIRONMENTAL PERFORMANCE

One demonstration of ExxonMobil's commitment to **Protect Tomorrow. Today.** is the level of environmental mitigation built into the proposed Project, including measures to avoid or minimize impacts related to specific environmental resources (Sections 4.1 through 4.17). Additional mitigation is provided through Project-wide programs that help to avoid or minimize potential environmental impacts and increase environmental performance, including Waste Management (Section 4.18) and Spill Prevention and Response (Section 4.19).

(This page intentionally left blank.)

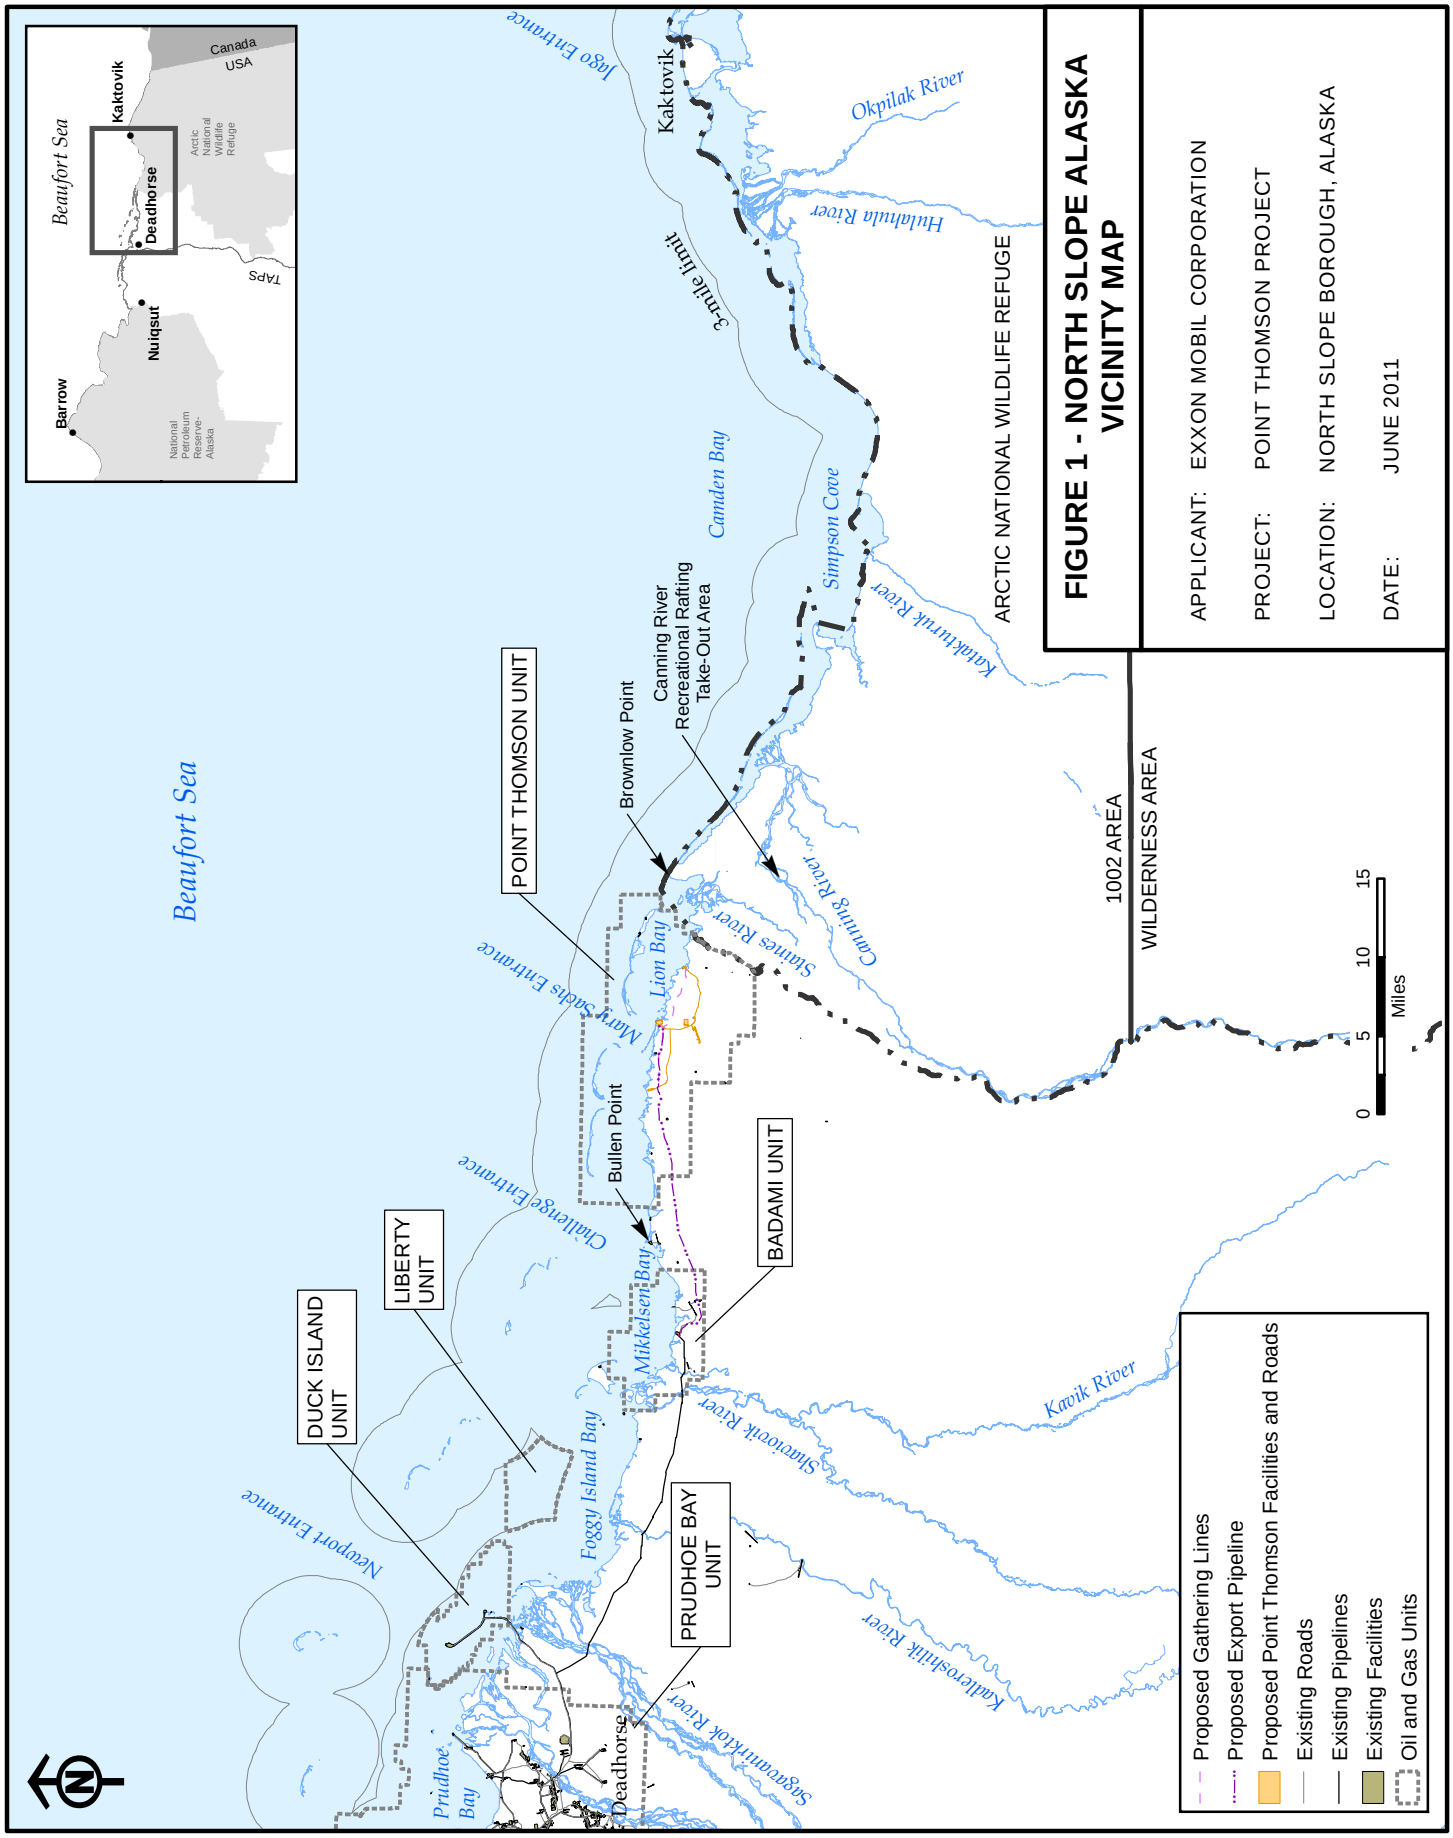
3.0 OVERVIEW

The proposed Project includes installation of the necessary facilities and infrastructure to: drill and produce five development wells; separate and stabilize hydrocarbon liquids from the natural gas and re-inject residual gas; and transport hydrocarbon liquids through an approximately 22-mile long export pipeline to existing common carrier pipelines for delivery to TAPS. **See Figures 1 through 3** (at end of section).

ExxonMobil has made it a priority to avoid or minimize impacts throughout planning and design of Project development. Initially, a two-stage screening process was utilized to: 1) screen out components that could meet Project needs, but had significant environmental drawbacks, and 2) to further evaluate and rank those components with the highest potential for meeting Project needs, while avoiding significant adverse environmental effects.

Stage 1 screening considered, but eliminated from further consideration in Project planning: well pads on offshore platforms, manmade islands, and barrier islands; solid fill causeways and docks; and a gravel access road from Deadhorse.

Stage 2 screening evaluated numerous options for locating or designing Project components, with consideration for effectiveness and practicability in producing and transporting hydrocarbon liquids and for the potential to avoid, or minimize, adverse environmental effects. This level of evaluation refined the options considered for Project development and resulted in ExxonMobil's current proposal for:



- Drilling and processing facilities on pads located near the coast to optimize use of long reach directional drilling (LRDD) for effective reservoir development and allow consolidation of drilling and processing facilities, which minimizes the footprint.
- Large module delivery by sealift to Point Thomson, using a temporarily grounded barge-bridge for loading and unloading rather than transport via sea ice road, with inherent inefficiencies, uncertainties, and risks.
- An approximately 12-mile infield gravel road system connecting all major facilities to minimize in-field helicopter traffic, noise, off road vehicle traffic, and health and safety concerns.
- The Point Thomson Export Pipeline (PTEP) and gathering lines will be elevated at a minimum of 7 feet above tundra surface, rather than insulated and buried pipelines.
- An elevated flare system, rather than an enclosed or ground system, both of which require considerably larger footprint.

This EMR describes key mitigation measures to reduce adverse environmental impacts and ensure that the Project is environmentally sound. It provides discussion on the background behind development of various resource impact mitigation measures and summarizes key mitigation that has been incorporated into the Project to avoid or minimize adverse effects, as cross referenced in **Table 1** and more fully discussed in Section 4.

Table 1 Summary of Project Mitigation

Resources Evaluated	Focus of Mitigation	Page
Permafrost	Maintain thermal integrity.	4-1
Wetlands	Avoid impacts by using existing fill and minimizing new footprint; avoid higher value wetlands.	4-3
Hydrology	Maintain existing drainage and sediment transport patterns; maintain habitat function; minimize erosion.	4-9
Water Quality	Control runoff, minimize erosion and sedimentation, manage water use, and minimize surface discharges.	4-15
Physical Oceanography and Coastal Processes	Avoid major marine fill and dredging; minimize disturbance to the seabed and littoral drift patterns; and avoid impacts from coastal erosion, storm surge, and wave runup.	4-18
Terrestrial Mammals	Avoid/minimize disturbance, obstructions, behavioral changes, and habitat alteration.	4-21
Birds	Minimize disturbance, obstructions, and habitat alteration.	4-24
Marine Mammals	Minimize disturbance, behavioral changes, and habitat alteration. Avoid or manage encounters.	4-26
Fish and Fish Habitat	Maintain fish passage and water quality.	4-30
Air Quality	Minimize affects on air quality and reduce potential emissions	4-32
Land Ownership, Land Use, Land Management	Maintain consistency with land owner and land management policies. Avoid conflict with adjacent landowner/land use.	4-34
Socioeconomics	Provide North Slope Borough and State economic opportunities.	4-35
Cultural Resources	Identify and protect cultural resources.	4-37
Subsistence and Traditional Land Use Patterns	Support traditional subsistence use of area and avoid impacts on subsistence activities and resources.	4-38
Recreation	Minimize detraction from recreational experience of visitors to the area.	4-43
Visual Aesthetics	Minimize visual effect of Project features.	4-44
Noise	Minimize noise emitted by Project facilities and activities.	4-45
Operational Controls for Resource Protection		
Waste Management	Avoid and minimize potential impacts to the local environment, particularly wildlife and wildlife habitat	4-46
Spill Prevention and Response	Avoid and minimize potential impacts to all resource categories	4-48

Appendix A provides a cross-reference of Project mitigations discussed in this EMR, with the corresponding requirements of the Section 404 (b)(1) Guidelines.

4.0 PROJECT MITIGATION MEASURES: BY RESOURCE

This section is organized to broadly match the organization of the *Point Thomson Project Preliminary Draft EIS* resource categories to the extent that Project mitigation measures are applicable. The mitigation discussed below includes Project-specific mitigation developed by ExxonMobil, as well as agency-standardized practices expected to apply to the Project.

Each section below begins with a summary of key mitigation measures, followed by a description of the background context for developing mitigation, and then a discussion of mitigation measures developed to avoid or minimize impacts.

4.1 PERMAFROST

The Project area is generally underlain by continuous, ice-rich permafrost below a shallow active layer. Thawing of the permafrost can lead to instability in Project foundations, roads, pads, and bridges, as well as to changes in the natural landscape, which may, in turn, lead to other adverse effects – such as thermokarst or erosion.

4.1.1 Summary

An overarching Project objective is to prevent thermal degradation of permafrost, and the strategy to do so is to prevent or minimize heat transfer from Project features into the permafrost. Key mitigation measures related to permafrost will include:

- Placing a minimum of 5 feet of gravel fill.
- Elevating heated buildings or structures on pilings.
- Elevating off-pad pipelines containing warm (above freezing) fluids on vertical support members (VSMs).
- Minimizing or avoiding impoundments by maintaining natural drainage.
- Installing thermosyphons around wells to remove unavoidable heat transfer from wellbore fluids. Additionally, conductor piles will be insulated and the well annuli filled with an insulating gel to minimize heat transfer to the permafrost.
- Implementing operating procedures and maintenance programs to ensure the design measures remain in effect throughout the life of the Project.

4.1.2 Background Context

The presence of ice-rich permafrost is common across the entire Arctic Coastal Plain (ACP). An extensive amount of geotechnical investigation work has been conducted throughout the Project area to characterize and understand the local permafrost regime and properly design Project features to be compatible. In addition to previous geotechnical exploratory drilling work and Project design efforts, the boring program conducted from 2009 to 2011 includes about 100 borings in the Project area to gather information on soils, active layer depth, ground ice conditions, and ground temperatures. In addition, the thickness of the active layer in the Project area was assessed using a penetration tool at hundreds of locations. Ground temperatures were monitored using thermistors at numerous strategic locations.

4.1.3 Mitigation Measures

Key mitigation measures incorporated to avoid or minimize impacts to permafrost are discussed below by Project component.

4.1.3.1 Gravel Roads and Pads

Key civil engineering criteria to prevent permafrost degradation include the standard North Slope practice of placing a minimum of 5 feet of gravel fill for roads and pads. This design criterion provides adequate fill thickness to insulate the underlying permafrost by ensuring that the thaw front will not penetrate into the permafrost. Due to topographic variations, the average gravel fill thickness for the Project is expected to exceed 6 feet.

The mitigation measures related to hydrology (described in Section 4.3) are also critical for maintaining the integrity of the permafrost and stability of roads and pads. Of note, these include careful siting and design of pads, airstrip, roads, and bridges/culverts to promote natural drainage and avoid, or minimize, the creation of impoundments that can act as thermal sinks and create thermokarst.

4.1.3.2 Buildings and Process Facilities

Heated structures (e.g., permanent buildings and process modules) are typically elevated 5 to 8 feet above grade on pilings to prevent or reduce heat transfer to underlying soils and preserve the thermal integrity of the permafrost. This will allow free flow of air below the structures and avoid direct heat transfer from the structures to the ground surface. Unheated buildings or structures (e.g., cold storage warehouses) will not be elevated.

The flare tip will be at sufficient height to avoid thawing of the permafrost, while minimizing height to reduce visual impacts.

4.1.3.3 Pipelines

Off pad pipelines containing warm or hot fluids will be elevated on VSMs 7 feet or more above the tundra. If such pipelines were buried in the Project area – a common practice at lower latitudes – thawing of the permafrost would occur, causing subsidence and threatening the integrity of the pipelines.

When crossing roads, the PTEP and gathering lines will be installed inside an oversized casing with carrier pipe isolators and insulation beneath the casing to protect the underlying permafrost from damage and thaw settlement, as well as to ensure long-term integrity of the road surface.

4.1.3.4 Wells

Production, injection, and disposal wells transport warm or hot fluids through the permafrost and can cause local thawing of the permafrost around the wellbores. The conductor piles will be insulated and the well annuli filled with an insulating gel to minimize heat transfer to the permafrost.

Also, to counteract the near surface thawing, thermosyphons will be installed to remove heat and prevent subsidence. These devices are successfully used extensively in Alaska under similar services.

4.1.3.5 Operations and Maintenance

To ensure long-term integrity of the permafrost and operations, ExxonMobil will conduct a maintenance program to ensure proposed mitigation measures remain effective for the life of the Project. This will include maintaining gravel depth according to design measurements (hence the need for a long-term gravel stockpile after the Project mine site is closed), maintaining culverts and bridges to provide unimpeded water flow, and maintaining well thermosyphons.

4.2 WETLANDS AND OTHER WATERS OF THE U.S.

Most of the Project area and surrounding areas comprise wetlands, streams, lakes, and marine waters that are subject to USACE jurisdiction under Section 404 of the CWA. The principal environmental concerns for development of the gravel mine site and placement of gravel fill include the tundra footprints (impact to, or loss of, wetlands habitats), hydrology, and habitat – with any associated impacts to wetlands, such as dust shadows from vehicle traffic on gravel roads. Hydrology is discussed in Section 4.3 and habitat is further discussed in Sections 4.6, 4.7, and 4.9.

4.2.1 Summary

Key mitigation measures related to wetlands, streams, lakes, and marine waters will include:

- Minimizing gravel fill by utilizing three existing gravel pads in the area to the greatest extent possible, thereby reducing overall new tundra footprint by more than 20 acres.
- Minimizing the size of the gravel pads through optimizing Project design and equipment layout.
- Using a temporary barge-bridge system to avoid placement of fill for a module offloading causeway/dock.
- Limiting module weights and barge loads, which eliminates the need to dredge an access channel for docking sealift barge, with associated offshore disposal of dredged materials.
- Designing pads, roads, bridges, and culverts to maintain natural drainage patterns and stream flows to the extent possible.
- Routing the infield gravel roads to minimize overall length and footprint, with consideration for hydrologic impacts and Project needs.
- Combining the East Pad Road with the Central Pad Road, minimizing hydrology impacts without increasing the tundra footprint.
- Routing the West Pad Road to avoid coastal marshes and estuarine habitat, while minimizing the wetlands footprint and hydrologic impacts.
- Utilizing ice roads and pads for Project access, pipeline construction, and temporary storage of mine site overburden.
- Watering gravel roads and pads, as necessary, to control dust generation.

4.2.2 Background Context

The Point Thomson Project area is located on the ACP, an area of almost 100 percent continuous ice-rich permafrost wetlands, and adjacent marine waters of the central Beaufort Sea. Gravel fill is required for Project development and some impacts are unavoidable. However, the Project incorporates design, siting, construction, and operations mitigation measures that avoid impacts to wetlands and other aquatic resources, when practicable, and minimize such impacts when they cannot be avoided, as discussed below.

The mitigation of impacts to wetlands and other waters of the U.S., as described below, includes both measures that significantly avoid impacts (e.g., through use of existing pads) and reduce impacts (e.g., optimization of facility layouts to reduce footprints). Appendix A provides a cross-reference of Project mitigations with the corresponding requirements of the CSW §404 (b)(1) Guidelines. Compensation for unavoidable wetland impacts will be addressed in the Section 404 permit applications.

4.2.2.1 Avoiding Discharge of Fill to Waters of the U.S.

Due to the Project's location on the ACP, which is dependent on the predominantly offshore location of the Thomson Sand reservoir, it is not possible to avoid development in wetlands, while meeting Project purpose and needs. Siting of Project facilities was based on the location of the Thomson Sand reservoir. The nearest extensive upland areas (i.e., areas with limited jurisdictional wetlands) are in the northern foothills of the Brooks Range, approximately 20 miles south of Central Pad. This distance is far beyond the technological capabilities of LRDD or practicable placement of non-drilling facilities.

While there are no practicable, non-wetland alternatives to the proposed Project, ExxonMobil has avoided impacts by eliminating three major development options or components included in earlier development proposals. As described in Section 3.0, the following components were eliminated from the proposed Project, avoiding related discharges to waters of the U.S:

- Offshore development potentially including gravel islands, drill sites on barrier islands, and/or subsea pipelines.
- Gravel causeway or solid fill dock for barge access and off-loading.
- Gravel access road to/from Prudhoe Bay.

In addition, providing optimum access to reservoir resources through LRDD from pads on the coast avoids the potential future need for more drilling pads to support full field development, which could be required if the initial drilling pads were located further inland.

4.2.2.2 Minimizing Discharge of Fill to Waters of the U.S.

Because it is not possible to completely avoid discharging fill in wetlands, the Project has minimized related impacts to the extent practicable. Related mitigation measures include optimizing Project design to reduce the extent of discharge and associated environmental impact, while meeting Project needs. A summary is provided below, with a more detailed discussion provided in Section 4.2.3.

The proposed three-pad configuration (Central, East, and West Pads) is expected to meet reasonably foreseeable future field development scenarios (e.g., expanded gas cycling and/or

gas sales). These pads, combined with LRDD technology, allow the hydrocarbon resources to be evaluated and developed with minimal future expansions (e.g., new facilities).

The three processing and/or drilling pads are the minimum size necessary to meet required drilling and processing needs. Two of these three pads utilize existing gravel pads, minimizing overall new fill requirements. Another existing pad (Alaska State C-1 pad) will be used to provide valuable storage space, with a minimal volume of new gravel fill required and no new footprint.

The 5,600-foot Project airstrip was located inland to accommodate local weather conditions and sized as the minimum required to accommodate the large cargo aircraft needed to meet Project needs. Some gravel pads originally proposed for navigation aids have been eliminated or replaced with piling-supported structures to accommodate the local hydrology, but also reduce wetlands footprint.

The infield gravel road system is the minimum required (approximately 12 miles) for efficient and safe year-round Project operations. Additional information provided in Section 4.3.3.2 explains the tradeoff between road length and routing criteria.

The Project mine site was located to minimize footprint while meeting gravel quantity and quality requirements. It also is being designed to support rehabilitation as a high functioning wetland and wildlife habitat.

4.2.3 Mitigation Measures

Key mitigation measures incorporated to avoid or minimize impacts to wetlands are discussed below, by Project component.

4.2.3.1 Central Pad

The Central Pad location was chosen to accommodate LRDD for field development, access by barge with minimal dredging and screeding, and integration of the existing PTU-3 gravel pad. The location also allows launching emergency response vessels in a sheltered environment. The Central Pad configuration was designed to avoid expansion into adjacent water bodies to the west. Therefore, expansion of the Central Pad beyond the existing PTU-3 Pad extends to the south, on the highest ground available. Light Detection and Ranging (LIDAR) and ground topography surveys were used to support this location.

There are many requirements for the Central Pad that must be simultaneously met to successfully support the Project, including: drilling, processing, marine transportation, camps, construction staging, storage (e.g., fuel, drilling chemicals, and equipment), and other infrastructure. Each of these Project elements requires a minimum area or spacing dictated by such factors as number of wells, spacing, rig and module sizes, safety zones, and vehicle access.

More specifically, eight well slots are provided to accommodate potential future drilling without additional gravel, and 40-foot spacing is required between each slot to meet operational requirements. Space is required on the pad for the rig to move to the well slots during construction and operations (e.g., additional drilling or well work). Also, the pad layout provides space for the sealift modules to move off the bulkhead and around the wells with the drill rig in place. A 30-foot wide corridor circumscribes the pad surface to provide security, fire, and

perimeter access. Safety standards require that occupied buildings and living quarters be located outside a 750-foot blast radius from the process areas and outside a 200-foot radius from the wells and fuel storage area. A Project challenge has been to meet these requirements while minimizing the pad footprint.

Design measures to minimize the Central pad footprint will include:

- Reducing the spacing between equipment in the process and power modules (i.e., between equipment and piping) specifically to reduce the footprint while maintaining minimum required spacing for equipment, maintenance and repairs, and safe operations.
- Consolidating buildings and space requirements, such as: providing common areas for vehicle access, sharing storage facilities, and consolidating spill response space with operations and maintenance buildings.
- Combining high pressure and low pressure flare stacks and locating the stack as close as practicable to the process facilities.
- Using large sealift modules for process and power generation facilities (vs. truckable) to reduce the footprint of the gravel pad and reduce onsite construction and related schedule impacts.
- Designing the Central Pad configuration to provide for the smallest incremental footprint for potential future development, such as expanded gas cycling or gas sales.
- Providing multi-use space in the construction camp area, which will also be used at a later time for operations lay down and for emergency response staging.

4.2.3.2 East Pad

The East Pad location was chosen to accommodate LRDD for field development and to effectively incorporate the existing North Staines River No. 1 gravel pad, resulting in the “L” shape. This reduced the amount of new gravel required for East Pad. The eastern edge of the North Staines River No. 1 Pad is susceptible to coastal erosion over the Project life, which makes it unsuitable for well and pipeline installation, but is sufficiently set-back for temporary use, such as drilling rig camps or staging/storing supplies. Pad coastal setback criteria are further discussed in Section 4.5.3.2.

LIDAR, aerial photography, and ground topography surveys were used to determine the best area for expansion of the North Staines River No. 1 Pad. Expanding the pad in another direction would have required either more gravel fill (e.g., to the north due to lower ground) or resulted in closer proximity to Stream 28 (e.g., pad expansion to the south).

The size of East Pad is the minimum necessary for: the required eight well slots on 40-foot centers; the drilling rig necessary to drill the high-departure, high-pressure wells; production facilities; associated infrastructure; and safety setbacks.

4.2.3.3 West Pad

West Pad was strategically located to evaluate and develop the western portion of the reservoir using LRDD. There are no existing gravel pads in the vicinity. The specific location and shape of West Pad was selected to be on higher tundra. The October 2009 Project Description showed part of the West Pad encroaching on a water body west of the pad. The pad was subsequently reconfigured to avoid such large water bodies.

The size of West Pad is the minimum necessary for: the required eight well slots on 40-foot centers, the drilling rig necessary to drill the high-departure, high-pressure wells; production facilities; associated infrastructure; and safety setbacks. Pad coastal setback criteria are discussed in Section 4.5.3.2.

4.2.3.4 In-field Gravel Roads

Hydrologic functions and wetlands are integrally linked. Project activities and infrastructure that affect hydrology can potentially have an impact on wetlands. Section 4.3.3.2 describes how road routes were developed (generally locating roads on higher and drier tundra wetlands and in areas with defined stream channels, as opposed to areas where un-concentrated surface runoff predominates). Main components of the infield road system include: the Central Pad Road from Central Pad to the airstrip and Alaska State C-1 Pad; East Pad Road from East Pad to Alaska State C-1, where it joins Central Pad Road; and the West Pad Road from West Pad to Central Pad Road north of the airstrip.

The proposed road routes carefully balance the amount of fill required, wetlands impact, and maintenance of the hydrologic regime. Specifically, the road routes are designed to avoid water impoundments, to maintain natural drainage patterns, and to minimize changes to stream velocities and sediment transport regimes through effective design of stream crossings (i.e., bridges, stream culverts, and cross drainage culverts). The hydraulic design of these structures complies with or exceeds all applicable codes and standards, including the Alaska Department of Transportation and Public Facilities (ADOT&PF) highway design standards (*Alaska Highway Drainage Manual*).

4.2.3.4.1 Central Pad Road

The Central Pad Road follows a direct route to the Alaska State C-1 Pad, with access to the mine site, airstrip, and Water Access Pad, minimizing overall road length and footprint.

4.2.3.4.2 East Pad Road

The East Pad Road route optimized the tundra fill requirement and surface hydrology to minimize impacts to both. As described in Section 4.3.3.2, the East Pad Road route was based on hydrologic criteria, as well as location on higher and drier tundra wetlands. For example, the approach to East Pad follows along a low ridge located between lakes and ponds to the west and Stream 28 to the east, thus avoiding placement of fill in lakes and riparian habitats.

4.2.3.4.3 West Pad Road

The principal design consideration in routing the West Pad Road was avoiding coastal marsh, estuarine habitat, lake basin, and storm surge areas – while still minimizing the overall length and footprint. This resulted in locating the road 0.5 to 1.0 miles inland. A more inland route would increase the road length and the gravel footprint and magnify hydrology issues.

4.2.3.5 Mine Site

The Project mine site minimizes footprint while meeting gravel quantity and quality requirements and supporting rehabilitation of the site as high value habitat. The selected mine location provides the most efficient gravel haul operation, while minimizing the number of truck haulage trips and related impacts (e.g., dust, air emissions, and noise). The mine site is close to the

Central Pad Road and adjacent to the second largest single gravel requirement – the airstrip. Based on geotechnical data, the mine site was re-oriented in an east-west direction, which has less overburden, resulting in a smaller tundra footprint.

The mine will be developed in two 20-foot gravel “lifts” after the overburden is removed. This depth of mine is appropriate for the mining technique (drill and shoot) planned, and minimizes the tundra footprint when compared to a single lift, shallower mine. The gravel stockpile area located at the west end of the mine pit could serve as an expansion area of the mine site (i.e., a new cell) for potential future development, thus minimizing future tundra impacts.

The *Point Thomson Project Mine Site Mining and Rehabilitation Plan* (Rev. 1, 2011) details the mine rehabilitation and expected habitat enhancement benefits of the rehabilitation plan (e.g., creating shallow littoral zones from the overburden placement to provide habitat for waterfowl and other wildlife). To minimize impacts to adjacent wetlands during construction, overburden will be temporarily placed on seasonal ice pads and transferred back into the mine before breakup. The Rehabilitation Plan includes returning most of the overburden to the mine site. This eliminates additional impacts to the tundra from creation of overburden stockpiles, which is typical of other North Slope mine sites. Also, some of the organic overburden will be placed in other locations and then seeded to the extent there are beneficial uses for it.

4.2.3.6 Airstrip

As with other major gravel facilities, the principal environmental issues with the Project airstrip are impacts to wetlands and hydrology. Section 4.3.3.5 describes hydrology issues, impacts, and mitigation associated with the airstrip.

The size of the airstrip is determined by the largest aircraft planned for use, which is an L-100 (civilian equivalent of the C-130 Hercules). This relatively large cargo aircraft is commonly used throughout Alaska. While L-100-type aircraft will not be used routinely, they are an integral component in the Project’s logistics and emergency response plans. The 5,600-foot-length and 200-foot-width of the airstrip are driven by operator requirements for an L-100 and Federal Aviation Administration (FAA)-stipulated safety zones. It is essential for safe and efficient Project development for the airstrip to provide major emergency support capabilities.

The orientation of the airstrip is determined by the prevailing wind direction. The airstrip location approximately 3 miles inland minimizes coastal fog related operational down time, and places it in close proximity to the gravel source. A structure of this length will unavoidably affect water flow to some extent. However, the airstrip has been designed specifically to reduce the impedance to water flow and potential erosion of the gravel fill. Design mitigation includes eliminating gravel spur roads and pads supporting navigation aids along the south side of the runway to facilitate efficient break-up flood flows and avoid impoundments. This, along with other minor modifications, also resulted in a smaller overall footprint than the original design.

4.2.3.7 Pipelines

As addressed under Permafrost (Section 4.1.3.3), off-pad pipelines containing warm or hot fluids will be elevated on VSMs to prevent transferring heat from warm pipelines into the permafrost. Elevated pipelines have minimal impact to wetlands, and the VSMs have a total footprint of less than 0.1 acres for the entire Project.

The waterline between Alaska State C-1 pit and Central Pad, included in the *2009 Project Description* design, was eliminated to mitigate habitat concerns, which also eliminated approximately 0.2 acres of timber supports on the tundra.

4.2.3.8 Dust Control Measures

Impacts to the adjacent tundra from fugitive dust is a recognized environmental concern in other areas of the ACP. For the Project, dust will be controlled by watering the gravel roads and pads.

It is noted that the Project includes only about 12 miles of gravel roads, and the volume of traffic will be relatively light, particularly following completion of gravel construction. By comparison, the hundreds of miles of roads throughout the Prudhoe Bay area, combined with significant daily and year-round traffic, present a much greater challenge to road dust mitigation. At Point Thomson, a water truck is capable of watering all of the roads and pads in a single day. As a result, frequent road watering for dust control at Point Thomson will be feasible and, combined with the relatively light traffic volume, will help minimize dust impacts.

4.2.3.9 Ice Roads

Ice road construction, use, and proposed routes are regulated and monitored by the Alaska Department of Natural Resources (ADNR) and the NSB. Specific standards designed to protect tundra vegetation and water resources must be met before an ice road is approved for winter construction, including the type of equipment used. In addition, ExxonMobil has established, and put into practice at Point Thomson, an ice road program that establishes rules for ice road use and requires training for all drivers and travelers. The program also has a monitoring component to ensure compliance with ADNR and NSB standards and permit requirements.

A number of different tools are used for ice road route selection including topographic maps, aerial photos, forward looking infrared (FLIR) surveys, and overflights. Routes are selected specifically to avoid tussock tundra to the extent practicable, to optimize stream crossing locations, and avoid polar bear dens. Overflights in the summer season, followed by fall inspections, will help identify areas to avoid (e.g., steep stream banks), or for special protection (e.g., rig mats). ADNR will approve the final route.

Travel on ice roads will be subject to strict guidelines to avoid tundra damage (e.g., ice road training, established speed and weight limits, and delineators along both sides of the road). Prior to breakup, ice roads will be slotted at designated stream crossings so that breakup flow is not impeded. Following breakup, the ice road route will be inspected in the summer to confirm no tundra has been damaged. This inspection is coordinated with representatives from the NSB and ADNR.

4.3 HYDROLOGY

Principal environmental concerns about development impacts on hydrology include changes in the surface drainage patterns, lake recharge, flooding, and scouring.

The Project components with the greatest potential to impact hydrology include: gravel fill placement for pads, roads, and airstrip; construction of ice roads; stream crossings by gravel and ice roads; and water withdrawal to support the construction, drilling, and operations phases. The following discussion addresses natural drainage patterns, stream stage (water level) and streamflow, stream velocity, and lake levels.

4.3.1 Summary

The Project mitigation strategy for gravel roads is to minimize hydrology impacts while limiting footprints to the smallest practicable. Roads are optimally located so that bridges and culverts can successfully maintain natural drainage patterns. For facilities that are not suitable for mitigation using bridges and culverts (i.e., pads and the airstrip), the Project mitigation strategy is to design them to the smallest size consistent with their purpose and locate them to avoid streams and impact the fewest number and smallest lakes practicable. The key mitigation measures related to hydrology include:

- Routing the infield gravel roads to minimize overall length and footprint, with consideration for hydrologic impacts and Project needs.
- Conducting field surveys during breakup and other times to identify natural drainage patterns and to measure streamflows at proposed road crossings.
- Routing infield roads a sufficient distance inland to avoid major stream crossings.
- Balancing the avoidance of lakes, ponds, and wetter tundra areas closest to coast with avoidance of areas further inland where unconcentrated overland flow predominates.
- Designing bridges and culverts at stream crossings for a 50-year flood design flow to reduce impacts to natural drainage to the extent practicable.
- Amending design to lengthen the bridge at Stream 24B to accommodate intercepted sheet flow[5].
- Installing cross-drainage culverts at approximately 500-foot intervals along the road system to maintain overland flow.
- Using a sheet pile design for bridge abutments to minimize the tundra footprint, road embankment erosion, and stream scour.
- Slotting ice roads at designated stream crossings to facilitate drainage during breakup.

4.3.2 Background Context

There are significant hydrologic differences between the Project area and other areas of the ACP. The eastern ACP, in general, and the Project area, in particular, contains fewer streams and lakes than the more westerly ACP. The Project area that will be impacted by gravel roads contains only nine small, defined tundra streams that originate on the ACP; none of the gravel pads directly impact these streams. Four of these streams contain gravelly bottoms, while five have grassy bottoms. The gravelly-bottom streams indicate sediment transport and have higher water flows, particularly during breakup, and infield roads will cross these streams using bridges. The grassy bottom streams indicate little to no sediment transport and commensurately lower flows, and infield road crossings will utilize culverts. Upstream of all the proposed crossings, the stream channels are poorly defined, and there is widespread overland flow (sheet flow).

The stream with the greatest flow that will be crossed by infield gravel roads (Stream 22B) has a predicted 50-year event flow of 900 cubic feet per second. In comparison, the flow for a 50-year

[5] Sheet flow refers to the wide-scale inundation and unconcentrated flow that occurs in much of the Project area during annual spring breakup events.

event for the larger rivers on the ACP (e.g., Colville, Sagavanirktok, etc.) varies from 20 to 800 times greater. In addition, the 50-year floodplain of Stream 22B is roughly 700 feet wide, while the 50-year floodplain of the Colville River is over 10 miles wide near the Alpine development. These Point Thomson area streams may, therefore, properly be considered minor, and most could feasibly have utilized culverts for infield road crossings. However, the Project has provided mitigation for more efficient flood flow and fish passage by providing bridges on the four largest streams.

Freshwater availability is generally limited on the ACP in the winter; this is particularly true in the eastern North Slope/Project area. Most natural lakes in the Point Thomson area are shallow (less than 5 feet) and freeze to the bottom during the winter. Therefore, gravel mines converted into reservoirs are very important as water resources. The 2010 *Point Thomson Project Hydrology Report* showed that both the Alaska State C-1 Pit and the Shaviovik Pit (west of the Badami development) naturally recharged during spring flooding following water withdrawal activities during the previous winter, which is consistent with lake recharge in other developed areas of the North Slope.

4.3.3 Mitigation Measures

Key mitigation measures incorporated to avoid or minimize impacts to hydrology are discussed below by Project component.

4.3.3.1 Pipeline Routing and Design

The PTEP and gathering line alignments avoid locating VSMs in lakes and cross streams at locations that minimize the need for VSMs in active channels. As noted above, off-pad pipelines will be elevated on VSMs to prevent transferring heat from warm pipelines into the permafrost. Such elevated pipelines have minimal impact on local hydrology.

4.3.3.2 In-field Roads

The most important measure mitigating road impacts on hydrology was elimination of a gravel road connecting Point Thomson with the Deadhorse area. Such a road would require placement of substantially more gravel and cross many more, and larger, rivers and streams. Associated impacts of these requirements would also be commensurately greater. By relying instead upon other modes of transportation (i.e., barging, aircraft, and ice roads), it was possible to reduce the gravel road system to the minimum required for efficient and safe year-round Project operations.

Critical prerequisites to selecting the infield road routes and designing bridges and culverts are field studies during breakup and other seasons. At Point Thomson, field studies were conducted in 2003, 2009, and 2010. The results of the 2009 and 2010 field studies are detailed in the 2010 Hydrology Report, which has been provided to the USACE, other Cooperating Agencies, and the third-party EIS consultant. The Project bridge and culvert designs, along with related analyses applying results of the field studies, are contained in the *Point Thomson Project 2010 Hydraulics Report*, which was provided to the same parties.

The Central Pad Road follows a direct route to the Alaska State C-1 Pad, with access to the mine site, airstrip, and Water Access Pad. This routing crosses two streams, with one culvert and one bridge located upstream of identified anadromous fish habitat. The East Pad Road is optimally routed to balance hydrologic and wetlands impacts, using culverts to facilitate normal

drainage patterns. Culvert batteries are proposed for the three stream crossings along the East Pad Road.

The road alignment from Central Pad to East Pad intercepts the five streams at an approximate 90-degree angle, which minimizes crossing length and is the most efficient for conveyance of flood flow. Individual cross-drainage culverts will be installed along the road to prevent local impoundments of overland flow through polygon cracks or low points. The East Pad Road location is approximately 2 miles inland and close to the hydrologic transition between distinct stream drainage basins and the area where wide-scale, undefined overland flow and ephemeral (indistinct) drainages characterize the hydrologic regime. This transition is clear in aerial photographs of the Project area. Locating the East Pad Road further inland would increase the likelihood of substantial impounding due to the predominant unconcentrated overland flow hydrology. The number of required culverts would increase, but their effectiveness would be reduced. Where the drainage is less defined, it is more difficult to identify where culverts are required. Where insufficient or improperly placed culverts are installed, surface impoundments are more likely to occur, potentially leading to downstream hydrologic changes, geothermal regime changes, thawing of the permafrost, excessive settlement of roads, and increased maintenance.

The West Pad Road route also balances hydrological and wetlands impacts. The selected road route is, on average, about 1 mile inland. This route avoids the wetter tundra areas and higher density of lakes and ponds, and results in crossing streams where the channels and flood plains are smaller and better defined. Three bridges and one culvert battery are proposed for stream crossings along this route.

Locating the West Pad Road more inland to the hydrology transition zone (as described above for the East Pad Road) would place the route in the vicinity of the airstrip, which would result in an increased length and tundra footprint. Earlier designs also considered a more direct route from Central Pad to West Pad (i.e., route located closer to the coast), which would have involved crossing more streams with anadromous fish habitat, and necessitated longer bridges.

4.3.3.3 Bridges

Conducting hydrology studies as a basis for routing roads is the first step in mitigating hydrology impacts. The next step in developing mitigation is properly designing the bridges and culverts to maintain natural drainage to the extent practicable.

Based on the Point Thomson hydrology studies and agency consultation, three bridges will be 65 feet in length and one will be 40 feet in length. All bridges will be designed to support drilling rig movement. Bridges will be designed with clear openings between vertical sheet pile abutments, with openings 15 feet shorter than the bridge length. The piles supporting the bridge girders will be placed behind the sheet piles, with no obstructions in the stream channels.

The curved sheet pile abutments provide an efficient means of stream flow passage and scour protection at the bridge abutments during higher water events. Use of vertical sheet piles avoids the need for other protective structures and allows unimpeded flow through the bridge openings. Alternatives to sheet piles typically include gravel fill abutments, which require toe protection, such as concrete revetment, riprap, or gravel bags and would reduce the size of the clear opening. The sheet piles will be outside of the active stream channels at normal water levels, set back beyond the stream banks. During higher water events, the sheet piles will provide a barrier between the road fill and stream channels, protecting the streams from siltation.

The bridges are designed to pass a 50-year flood, with additional reserve capacity for larger floods. The hydraulic design of the bridges used USACE HEC-RAS and ABSCOUR computer programs in calculating adequate opening size, bridge deck height, and scour resistance.

4.3.3.4 Culverts

Culverts serve two functions: maintaining stream flows and cross drainage. Location and type of culverts along roads was based on extensive field reconnaissance, photography, and topographical and hydrological survey data.

During breakup studies in 2009 and 2010, field engineers and hydrologists recorded locations where stream crossing and cross-drainage culverts would be needed. In addition, all of the Project road routes were walked in the summer of 2010, and Global Positioning System (GPS) coordinates were taken at low areas, wet spots, and polygon troughs to mark culvert placement locations. Where available, photographs taken in the field were used to confirm or adjust culvert placement and orientation. Topographical survey data and LIDAR imaging were used to make minor adjustments to location and/or orientation.

On the North Slope, structural steel line pipe material rather than Corrugated Metal Pipe (CMP) or multi plate pipe is desired for culverts due to issues related to installation with frozen fill, changes to the thermal regime, structural capacity of the steel, and culvert inlet/outlet maintenance due to stream flow and ice. Culverts using structural steel line pipe perform better in accommodating differential settlement and supporting heavy rig and module loads. The structural integrity of CMP relies upon the surrounding soil for support, which can be problematic. When gravel placed in winter months thaws during spring, the soil surrounding the culvert compacts and subsides. As a result, CMP culverts can fail due to the loss of soil support. Differential settlement of the surrounding soil can also cause CMP failure and/or uplift of culvert ends, which affects water passage capacity. Compared to CMP, structural steel line pipes reduce the amount of road fill placed over the culverts.

Following installation, culverts will be inspected periodically as part of routine operation and debris will be removed, as required.

4.3.3.4.1 Stream Crossing Culverts

Stream crossing culverts will be placed at five locations. Each stream crossing was reviewed to determine the necessary size and number of culverts. The culverts have been sized to accommodate the 50-year stream flow, with a backwater depth not exceeding the top of the culvert batteries. These conservative criteria provide reduced velocities and minimize erosion potential. By comparison, the ADOT&PF culvert design criteria allow inlet water elevations to be 50 percent of the culvert diameter above the top of the culvert.

In consultation with Alaska Department of Fish and Game (ADF&G), two streams containing fish will be provided with hybrid culvert batteries designed for fish passage. Streams 18A and 24A will use structural steel line pipe culverts, with a single corrugated, multi-plate culvert to meet fish passage criteria. The multi-plate culvert will be installed along the thalweg[6] of the drainage. Culverts for the other three streams (Streams 23, 26, and 27) will use structural steel line pipe.

[6] Thalweg refers to the continuous line of maximum depth along an active stream channel

4.3.3.4.2 Cross Drainage Culverts.

Cross drainage culverts will be located, on average, at 500-foot intervals along the Project gravel roads to mitigate potential water impoundment. The distance between cross drainage culverts will vary slightly, based on site-specific conditions. Cross drainage culverts will generally be positioned so that the end of the culvert on the upgradient side of the road is centered on a local low spot, where it is likely that water would otherwise be impounded at the road. During spring breakup after road construction, observers will evaluate the effectiveness of the installed culvert network and identify whether additional cross drainage culverts are needed to avoid water impoundment.

4.3.3.5 Airstrip

The Project airstrip is located about 3 miles inland to minimize the effects of coastal fog on aircraft operability. The prevailing wind directions necessitate a northeast-southwest orientation for take-off and landings. The airstrip length is determined by aircraft type, operator requirements, and FAA safety criteria.

Installation of culverts under the airstrip was considered, but eliminated as impracticable, because such culverts would be ineffective in transporting the water. The natural, uneven surface of the tundra, combined with the prospect of differential settling and the width to be traversed (i.e. culverts would need to be over 230 feet long), would prevent culverts from having a consistent slope. Because the airstrip does not cross any defined stream channels, water that is redirected along the south edge would remain shallow, reducing the effectiveness of culverts to transport flow to the north.

No significant impact on hydrology from the airstrip is expected, because the natural topography and airstrip design allow surface water drainage to be maintained with minimal impoundment. Hydraulic modeling and survey data indicate that the airstrip will intercept some surface water flow from two streams: 22A and 23. However, due to the orientation of the airstrip and the interception angle of 45 degrees to the existing ground slope, water from these streams will flow towards Stream 24B rather than creating an impoundment adjacent to the airstrip. To maintain this flow, proposed navigation instrument gravel pads/spurs along the southern boundary of the airstrip were eliminated from the design and relocated to the north side, or functionally replaced with pile-supported structures. Additionally, the bridge length for the infield road crossing of Stream 24B was increased to facilitate surface drainage and mitigate impacts of the intercepted drainage.

As noted in the 2010 Hydraulics Report, during a 50-year flood event, water depths upgradient of the airstrip (i.e., along the south side) are predicted to vary between 0.4 and 1.5 feet, with an average depth of 1 foot at the airstrip toe, and with predicted maximum velocities at the toe of 2.4 feet per second. The hydraulic analysis supports the plan to utilize slope protection along the south edge of the airstrip to mitigate potential erosion and sediment transport. To accomplish this, organic overburden from the gravel mine will be placed along the upgradient (south) side of the airstrip and seeded to promote vegetation growth and minimize erosion.

4.3.3.6 Ice Roads

Some of the ice road mitigation measures affecting wetlands (discussed in Section 4.2.3.9) also apply to hydrology. Additionally, onshore ice road routes will cross streams at locations where the streams are known to naturally ground to the bottom. Where this is not the case (e.g.,

deeper river channels), the thickness of the ice road will be limited to ensure free passage of water under the road. Slotting of ice roads at designated stream crossings to facilitate drainage and minimize impacts to hydrology during breakup is a key ice road mitigation measure.

4.3.3.7 Water Use

Project mitigation measures have been developed to address requirements of ADNR and ADF&G water use permits and avoid adverse impacts to water resources. ExxonMobil has completed surveys of lake size and bathymetry to determine volumes of lake water withdrawal that are protective of water availability and water quality. A process has been implemented to document water sources used and location of use. ExxonMobil will monitor waterbody recharge, as needed, or directed, by ADNR and/or ADF&G in the future.

4.4 WATER QUALITY

Hydrology and water quality are integrally linked, and many of the measures described in Section 4.3 also serve to protect water quality. This section specifically addresses freshwater and marine water quality protection and water management issues.

Water quality concerns associated with developing and operating a remote oil and gas facility on the North Slope include permitted discharges, potential spills, erosion and sedimentation, lake water withdrawal, and activities in nearshore marine waters (e.g., sealift and coastal barge support).

4.4.1 Summary

For purposes of this discussion, freshwater and marine mitigation measures are summarized separately. Mitigation measures common to both are more fully described in Section 4.4.3.

4.4.1.1 Freshwater

Project activities with the greatest potential to affect freshwater quality are permitted discharges, potential spills, road and pad erosion, and lake water withdrawal. Use of bridges and culverts along roads with associated water quality protection benefit was discussed in Sections 4.3.2 and 4.3.3. Spill prevention and response measures are described in Section 4.19. Key mitigation measures related specifically to freshwater quality include:

- Reducing surface discharge of wastewaters through use of a disposal well, including zero discharge of produced water and drilling wastes.
- Managing snow melt and runoff under site-specific Stormwater Pollution Prevention Plans (SWPPPs) to protect water quality.
- Designing storage and transfer locations for fuels and other fluids with appropriate secondary containment systems and site-specific procedures (e.g., drip pans/duck ponds and pads underneath equipment).
- Implementing various BMPs, such as the Drips and Drops Program, for road and pad maintenance (e.g., vehicle inspections).
- Slotting ice roads at designated drainage paths to reduce the potential for erosion and sedimentation during breakup.

- Implementing dust control measures for roads and construction areas to avoid impacts of dust on nearby water bodies.
- Designing bridges and culverts to maintain existing surface drainage patterns and prevent erosion.

4.4.1.2 Marine Water

Project activities in marine waters are associated with coastal and sealift barge operations, as well as potential construction of sea ice roads during the winter. Key mitigation measures applicable to marine water quality include:

- Optimizing module weight to eliminate the need to dredge a channel for barge access.
- Using a temporary barge-bridge system to eliminate a solid fill causeway/dock and minimize effects on the ocean bottom, littoral drift, and marine water quality.
- Constructing a permanent Service Pier on piles, not fill, for offloading coastal barges to reduce the number of barge trips and minimize disturbance to the ocean bottom and associated impacts to marine water quality.
- Installing mooring dolphins and pilings through the ice in the winter to minimize potential suspended sediment effects on water quality.
- Dredging the barge landing area through the ice during the winter preceding an open water sealift to minimize sedimentation effects on water quality. Limiting summer dredging/screeding to the minimum amount needed to maintain the appropriate seabed profile for barge landing.

4.4.2 Background Context

Based on data collected by ExxonMobil, ADNR, and the University of Alaska Fairbanks (Water and Environmental Research Center), water quality for the Project area is typical of freshwater resources across the North Slope. Water quality in North Slope lakes generally decreases throughout the winter. As ice forms, the concentration of dissolved solids increases and the concentration of dissolved oxygen decreases in the remaining free water. Withdrawal of water for construction of the ice roads and pads required to support winter construction activities can increase the magnitude of these changes. In spring when the lakes thaw and runoff enters the lakes, the concentrations of dissolved solids are reduced, while the dissolved oxygen concentrations increase.

Project production pads and infrastructure are located close to the coast to support reservoir development and marine transportation. Exclusive of the PTEP, major facilities are connected by infield gravel roads, which cross nine small streams. Project siting and design criteria developed for stream crossings will minimize potential effects on water quality. A detailed discussion of bridges and culverts, including flood and scour protection, is provided in Sections 4.3.2 and 4.3.3.

The project is remote from local community water supplies and there are no subsurface fresh water aquifers. Private water use in the area is limited to North Slope industry use.

4.4.3 Mitigation Measures

Key mitigation measures incorporated to avoid or reduce impacts to water quality are discussed below, by Project component.

4.4.3.1 Permitted Discharges

The Project has been designed for zero discharge of drilling and process wastes, based on construction of a Class I non-hazardous disposal well. Most other wastewaters are also planned for injection, although treatment systems have been designed for camp wastewater and hydrostatic test water. This results in effluent that meets regulatory criteria for permitted surface discharge, if needed. Alaska Pollutant Discharge Elimination System (APDES) and/or National Pollutant Discharge Elimination System (NPDES) permits will be obtained for use during construction and as a contingency for situations where the disposal well is unavailable. Discharges to the tundra and surface waters (fresh water and marine water) will be controlled by permit requirements, which are designed to prevent or minimize adverse effects to water quality. The Project SWPPP, as well as the Waste Management Plan (described in Section 4.18), also include BMPs protective of water quality.

Discharge of fill into wetlands and other waters of the U.S. will be conducted under the terms and conditions of a USACE Section 404 permit, for which a Section 401 Water Quality Certification is required prior to issue.

4.4.3.2 Spill Prevention and Response Planning

Prevention of spills is a crucial factor in the environmental performance of the Project. The prevention, design, detection reporting, response, and training measures described in Section 4.19 will also provide water quality protection.

Specific BMPs will be implemented to avoid or minimize water quality impacts. Fuel will not be stored and vehicles will not be refueled within 100 feet of waterbodies, unless otherwise approved by the appropriate regulatory agencies. Spill response equipment and materials will be readily available at designated locations throughout the facility

4.4.3.3 Siting, Design, and Best Management Practices

ExxonMobil has developed siting and design criteria and numerous BMPs to minimize runoff, erosion, and sedimentation. For example, pipeline and road alignments are located and designed to avoid or minimize water body crossings, thus minimizing drainage impairment and water quality degradation potential. Equipment skids and modules will be curbed to contain potential leaks. Gravel pads for drilling and processing facilities are designed such that water surface elevation associated with the 100-year flood or storm surge, plus a suitable freeboard, is at or below the top of the pads to reduce the potential for associated runoff that can degrade water quality. BMPs of the SWPPP will be in place to avoid or minimize the impact of snowmelt or rainfall to water quality. Snow removal and handling procedures will be in place to comply with the snow removal BMPs of the SWPPP. Dust control BMPs will also be in place for gravel roads, pads, and summer gravel mining activities, as well as gravel haul routes and construction sites, where needed to minimize dust effects on nearby water bodies.

Storage locations for fuels and other hazardous materials have been designed with appropriate secondary containment systems. BMPs for fuel and hazardous material transfer and handling

have been developed to reduce the risk of spills. Other practices that will be employed (e.g., inspections and protective measures like duck ponds) include BMPs described in the ODPCP and relevant BMPs from the *North Slope Environmental Handbook*.

An innovative system for offloading the large sealift barges was developed to avoid the need for a solid fill causeway/dock. This approach also reduces effects on the ocean bottom, littoral drift, and marine water quality.

Installation of mooring dolphins and piling for the Service Pier will occur through the ice in the winter, minimizing an increase in suspended sediments. Dredging the barge landing area through the ice during the winter preceding an open water sealift will minimize potential sedimentation effects on water quality. Summer maintenance dredging/screeding will be limited to the minimum amount needed to maintain the appropriate seabed profile for barge landing. This maintenance dredging/screeding would occur once each season, if required, and be limited to a small area in the vicinity of Central Pad, reducing the potential suspension of sediments in the marine water column. The small quantity of marine sediments from the dredging needed to prepare the sea bottom for barge landings will be placed along the shoreline above Mean High Water (MHW) to minimize potential sedimentation and water quality effects. Also, the proposed Service Pier will minimize the need to land the smaller coastal barges on the beach, which in turn reduces disturbance to the ocean bottom and associated impacts to marine water quality

During an earlier phase of the Project, ExxonMobil completed site-specific studies to evaluate potential marine water quality effects (*Physical Oceanography of the Point Thomson Unit Area: 1997 and 1998 Regional Studies, Meteorology, Hydrodynamics, Hydrographic, Bathymetry, and Water Chemistry in Lions Lagoon.* Prior to future dredging and screeding, ExxonMobil plans to confirm/update previous findings. ExxonMobil also completed site-specific studies to evaluate the erosion and sedimentation potential of coastal processes, as discussed in more detail in Sections 4.5.2 and 4.5.3.

4.4.3.4 Water Use

As discussed in Section 4.3.3.7, Project mitigation measures have been developed to address requirements of ADNR and ADF&G water use permits and avoid adverse impacts to water quality.

4.5 PHYSICAL OCEANOGRAPHY AND COASTAL PROCESSES

Concerns with physical oceanography and coastal processes include how marine-related components of the Project interact and potentially modify longshore sediment transport and alter the seabed or shoreline, and how natural coastal processes, such as coastal erosion, might affect the integrity of the Project facilities.

4.5.1 Summary

Key mitigation measures related to physical oceanography and coastal processes include:

- Using LRDD to develop offshore resources without placing drilling structures in marine waters.
- Using a barge-bridge system for module offloading to eliminate the need for a solid fill causeway/dock.

- Limiting dredging/screeding for the barge-bridge system and Service Pier to a small area in the vicinity of the Central Pad.
- Limiting structures in marine waters to six vertical piles for the Service Pier, eight mooring dolphins for barge landings, and a small boat launch at the shoreline.
- Locating the sealift bulkhead and approach gravel ramp for the Service Pier above MHW to minimize the effect on sediment transport or deposition.
- Maintaining the barge-bridge system in place for the minimum time period needed to offload the modules (estimated 2 to 4 weeks) each sealift open water season, which limits the effects on coastal sediment transport.
- Locating East (new part) and West Pads sufficiently back from coast to avoid impacts from coastal erosion, storm surge, and ice ride-up for the life of the Project.
- Providing slope protection for the Central Pad to protect against storm surge and wave run-up events.

4.5.2 Background Context

Meteorological-oceanographic data collected for the Project considered regional wind speed data, including 30 years of weather data at Deadhorse, in addition to information from the BORE numerical model studies of storm events, and tide gage data from Prudhoe Bay. The analysis included over 50 years of aerial photography and nautical charts to map shoreline and bluff locations and calculate the rate of erosion/shoreline retreat. Wave numerical modeling was applied to better understand the wave conditions inside the barrier islands. The available information was interpreted to provide a basis for understanding coastal processes in the Project area and for designing Project facilities near the coast.

The meteorological-oceanographic and shoreline change analysis indicates that the coastline in the vicinity of the Central Pad over the past 50 years has been relatively stable, but with larger, short-term changes in the spit that extends to the east. Aerial photography shows that the spit adjacent to the Central Pad was previously eroding and migrating westward, but recently that migration has changed to the east and the spit is growing, even though the predominant littoral drift direction is likely from east to west.

Potential maintenance dredging requirements were evaluated, based on bathymetry data collected at Project sites in the summers of 2008, 2009, and 2010. It is expected that limited screeding and/or dredging will be required during construction to access the barge-bridge system and service pier. The length of the Service Pier is sufficient such that minimal maintenance dredging or screeding should be required. In addition, the barge-bridge system only requires preparation of the seabed to a minus 6-foot contour, not dredging of an access channel.

4.5.3 Mitigation Measures

Key mitigation measures to avoid or minimize impacts to physical oceanography and coastal processes are discussed below by Project component.

4.5.3.1 Marine Infrastructure

The Project relies on marine transportation to meet significant Project logistics requirements, (e.g., delivery of large modules and bulk supplies of fuel and other consumables); however, this is accommodated with marine infrastructure imposing minimal impact on coastal processes (e.g., beach sediments and nearshore sediment transport).

A solid fill causeway/dock has typically been used on the North Slope for offloading large modules from sealift barges, with access channel dredging commonly required. In contrast, the Project plans to use up to three ocean barges temporarily grounded and ballasted at the shoreline to serve as a bridge to the sealift bulkhead for offloading large modules.

The first sealift barge will be grounded approximately 70 feet from shore and connected to the sealift bulkhead at the Central Pad via a steel ramp. A barge with a heavier load will be grounded right behind the first and will serve as the middle link of the barge-bridge. The last barge will carry the heaviest load (approximately 4,000 tons). This proposed module offloading strategy, which arranges the barges according to loaded weight, makes it possible to offload the proposed sealift modules without dredging a channel or building a solid fill causeway.

In addition, a Service Pier is proposed that will extend 70 feet offshore into 4-foot water depths, allowing more fully-loaded barges to access the site and reducing the number of barge trips by up to 50 compared to the number of beach landings. Only eight mooring dolphins are needed to support barge landings at the barge-bridge and Service Pier.

This limited infrastructure is a significant reduction from the proposed infrastructure for prior Point Thomson development plans and other North Slope developments. The barge-bridge system eliminates the need for an 800-foot long solid fill dock to deliver the same size modules. Further, the maximum module size has been downsized, which eliminates the need for channel dredging required for a heavier load and deeper vessel draft.

Some screeding and dredging of the seafloor may be needed in any year in order to maintain the seafloor profile needed to land barges as described in Section 4.4.3.3. It is estimated that the maximum volume to be dredged to establish the required seabed elevations will not exceed 1,500 cubic yards per construction season. If dredging is required, the dredged materials will be placed along the shoreline above MHW west of the area to be dredged. This location is far enough away from the barge offloading area so that the dredged materials are not expected to refill the dredged area. Some active sediment transport does occur in the area; however, the dredge materials are expected to contribute only a small amount of material to formation of local sand spits.

Coastal facilities are designed to have a minimal impact on the long shore transport of sediment and related coastal erosion or accretion. Pilings for dolphins and the Service Pier, and the small boat launch, are the only structures to be placed in marine waters. These are not expected to affect littoral drift. The bulkhead associated with the barge-bridge system is located above MHW, as is the approach gravel ramp for the Service Pier. The barge-bridge system is temporary – in place for the minimum time period needed to complete offloading (an estimated 2 to 4 weeks) for up to three construction/sealift open water seasons. There will be substantial gaps between the barges and between the first barge and the shore (approximately 60 to 80 feet), which will limit effects on coastal sediment transport.

4.5.3.2 Planning and Design for Coastal Erosion

Design criteria for the East and West Pads include accommodating LRDD for field development and sufficient setback from the coast to avoid the effects of coastal erosion, storm surge and wave run-up, and ice ride-up/pile-up.

The new section of gravel fill for East Pad was located 250 feet from the coast, extending along a trend of higher ground to provide a buffer against coastal erosion over the life of the Project. East Pad is also located on high ground such that 100-year storm surge and wave run-up are not expected to reach the pad. The West Pad setback from the coast was 410 feet, which was determined by the 100-year storm surge and wave run-up, combined with the eroded shoreline location after 30 years. Slope protection is not required due to the higher elevation and the setback distance. Critical facilities at both pads will not be exposed to ice during a 100-year ice ride-up event.

Based on the average coastal erosion rate over the period of record (1955 to 2009) shoreline erosion is determined to be about 2 feet per year for the East Pad and 4 feet per year for West Pad. Using this average erosion rate, pad setback is sufficient to provide protection of critical facilities from coastal erosion for more than 80 years. However, to be conservative, ExxonMobil considered the worst case erosion rates predicted to occur over the Project's 30-year design life. The worst-case erosion limits were determined by taking the maximum erosion rate observed (representing time periods of as little as 3 years) within the period of record (1955 to 2009) and applying that erosion rate over the entire Project life. Under this conservative design basis, the pad setback is sufficient to provide protection from coastal erosion during the 30-year design life.

Other siting and design factors include storm surge and wave runup. East Pad is at +17 feet, Mean Lower Low Water (MLLW) elevation and is above the 100-year return storm surge and wave run-up limit. West Pad is at +20 feet, elevation and is above the 100-year return storm surge and run-up limit

Because the Central Pad was designed to incorporate the existing PTU-3 Pad and to be close to the coast for barge access and launching emergency response boats, it was not possible to fully avoid coastal erosion by pad setback. Nonetheless, the existing pad will be elevated by adding 5 feet of gravel in order to be above the 100-year storm surge and wave run-up elevation. The slope protection proposed for the Central Pad generally relates to protection from run-up and overtopping of storm surge events more than retreat of the coastline due to erosion. During the life of the Central Pad, coastal erosion will be monitored and mitigation will be employed if erosion begins to threaten the pad. Critical facilities will not be exposed to ice during a 100-year ice ride-up/pile-up event.

4.6 TERRESTRIAL MAMMALS

Proposed development concerns associated with terrestrial mammals include habitat impacts, changes in behavior due to disturbance and activities, and direct impacts such as vehicle collision.

4.6.1 Summary

Many of the mitigation measures discussed for other resources, such as minimizing the size of gravel pads to reduce wetlands impacts, will directly or indirectly mitigate impacts to terrestrial mammals, particularly from a habitat perspective. Those measures are not repeated here.

Instead, the focus of this section is on the primary mitigation measures specific to potential Project impacts on terrestrial mammal behavior and direct impacts. The key mitigation measures related to terrestrial mammals will include:

- Elevating pipelines to provide a minimum clearance of 7 feet from the tundra for unimpeded wildlife movements.
- Conducting on-tundra gravel placement activities primarily during the winter to reduce the impact on wildlife.
- Constructing infield gravel roads to avoid aircraft and off-road vehicle travel between Project locations.
- Employing operational controls (e.g., road travel restrictions) and rigorous training programs.
- Eliminating the previously proposed aboveground waterline to mitigate agency concerns regarding potential effects on wildlife movement.
- Implementing a Polar Bear and Wildlife Interaction Plan with detailed measures to avoid adverse encounters with wildlife.
- Adopting strict management procedures specifically relating to the control and containment of waste containers and food.
- Requiring routine aircraft flights (e.g., transportation of personnel and cargo) to generally fly at a 1,500-foot altitude following a path inland from the coast to avoid disturbance to wildlife, except as required for takeoffs and landings, safety, weather, and operational needs, or as directed by air traffic control.

4.6.2 Background Context

The ACP area provides denning, foraging, movement, and insect relief habitat for resident and migratory terrestrial mammals such as brown bear, caribou, musk ox, and fox, as well as polar bear. (Polar bear are discussed in Section 4.8.2.)

4.6.3 Mitigation Measures

ExxonMobil's primary approach to minimizing habitat loss or alteration is minimizing the Project footprint as described in Section 4.2. Measures focusing on minimizing impacts to terrestrial mammal migratory patterns and other behavioral changes are addressed through design features and operational practices or controls. Key mitigation measures incorporated to avoid or minimize impacts to terrestrial mammals are discussed below by project component.

4.6.3.1 Facilities

Facilities have been designed and operational features included to avoid or discourage wildlife encounters and to protect wildlife and human safety (e.g., building walkways and doors, lighting, snow management, and traffic control). Heated modules and buildings will be elevated on pilings. At a minimum, the area underneath will be maintained as a clear space with no storage of equipment or materials. The use of detection technologies and deterrence measures will be evaluated for efficacy in a variety of on-site weather conditions and seasons. Early detection, observance, and avoidance are the preferred wildlife mitigation methods.

During construction and operations, it will be necessary to transport personnel, equipment, and supplies among the various Project locations. To reduce the need for aircraft and off-road vehicle travel, particularly close to the coast, infield gravel roads will be constructed to connect the Project pads, airstrip, and gravel mine.

Placing elevated pipelines in close proximity to roads might affect caribou movement patterns. Pipelines are, therefore, located a half-mile or more away from roads, except for short sections at the Central, West, and East Pads.

The PTEP and infield gathering lines will be elevated a minimum of 7 feet from the bottom of the lowest structure (including the pipeline itself) to the surface of the ground to provide clear passage for caribou and other terrestrial mammal movement and migration patterns. To keep the pipeline elevation relatively constant, the pipelines will be greater than 7 feet from ground surface along much of the corridor due to variations in topography. It is estimated that there will be clearances greater than 8 feet along approximately 50 percent of the pipeline corridor.

The elevated waterline that was originally proposed to run between the Alaska State C-1 water source and the Central Pad on timber sleepers was dropped from the design, which also eliminated agency concerns about potential impacts to wildlife movement.

4.6.3.2 Gravel Construction Activities

Gravel mining, using blasting, will only be conducted in winter and prior to breakup, during a time when many animals are absent from the area. Summer mining will be conducted with roto-trimmers. Gravel placement for pad and road infrastructure will be primarily conducted during the winter, which will reduce disturbance to wildlife using the area in summer (e.g., migrating caribou).

4.6.3.3 Operational Procedures and Controls

Effective operational procedures and controls will ensure that the workforce understands the mitigation measures and can implement them. Many of the mitigation measures identified below are, or will be, incorporated in ExxonMobil's Polar Bear and Wildlife Interaction Plan. ExxonMobil's management systems and processes are described in Section 2. Project management systems and processes that protect terrestrial mammals will include:

- Implementing spill prevention and response programs, as described in Section 4.19.
- Employing an onsite Subsistence Representative(s) from Kaktovik or other North Slope communities during periods of active construction and drilling. Use of Subsistence Representatives during long-term operations will be evaluated during the operational planning phase.
- Prohibiting hunting and fishing by ExxonMobil employees and contractors while personnel are assigned to, and working in, the Point Thomson area.
- Prohibiting feeding wildlife.
- Maintaining a clear space under modules and buildings to prevent creation of artificial den sites for foxes.
- Requiring workers to stay on gravel surfaces unless their job duties require them to be on the tundra.

- Managing food materials and food wastes such that they are unavailable to wildlife, including the use of bear-proof dumpsters at Project locations.
- Applying dust control measures to roads, pads, and summer mining activities to protect vegetation and terrestrial and aquatic habitats.
- Limiting speed on Project roads and giving right-of-way to wildlife.
- Requiring routine aircraft flights (e.g., transportation of personnel and cargo) to generally fly at a 1,500-foot altitude following a path inland from the coast to avoid disturbance to wildlife, except as required for takeoffs and landings, safety, weather, and operational needs, or as directed by air traffic control.
- Training in site operations, deterrence and hazing, waste management, and ice road operations.
- Using bear monitors to watch for wildlife and take proactive measures to avoid encounters with workers.
- Identifying specific actions to be taken in the event of an encounter.
- Coordinating with the USFWS and/or ADF&G on known polar bear and grizzly bear den locations and procedures.
- Proper handling and disposal of any animal carcasses encountered.

To ensure worker understanding and compliance with these measures, training programs and other awareness programs will be implemented. Communications, such as the monthly Environmental Bulletins, will be used to highlight environmental best practices associated with Project activities.

4.7 BIRDS

Proposed development concerns associated with birds include habitat impacts, changes in behavior due to disturbance and activities, and direct impacts such as vehicle and tower collision.

4.7.1 Summary

Many of the mitigation measures discussed for Terrestrial Mammals (Section 4.6) generally apply to birds and are not repeated here. Key mitigation measures generally unique to birds will include:

- Implementing operational controls to minimize nesting opportunities for predatory/ nuisance birds.
- Designing facilities to minimize potential for bird strikes, including structures and lighting.
- Rehabilitating the gravel mine to enhance habitat for waterfowl.

4.7.2 Background Context

Birds occurring in the Project area include waterfowl and other waterbirds, shorebirds, ptarmigan, passerines, and predatory birds (e.g., raptors, seabirds, and ravens). All of these species groups are known to breed in the Project area. The historical ranges of spectacled eider

and Steller's eider (both federally designated as threatened species) and yellow-billed loon (federally designated as a candidate species) include the Project area. Spectacled eiders use the Project area as breeding habitat only in very low densities, and inconsistently, from year to year. Steller's eiders have not been observed in the Project area in recent years due to contraction of their breeding range. Low numbers of yellow-billed loon occur in the Project area, but none are likely to breed there.

4.7.3 Mitigation Measures

Operational controls to minimize nesting opportunities to prevent population increases of predatory species (e.g., ravens) will include: blocking off nooks and crannies with fabric/netting or other bird nest deterrent, using scare devices to deter the birds when they land in places likely to be nesting sites, and removing nests as the birds try to construct them (before they have a chance to lay eggs).

The *Gravel Mine Rehabilitation Plan* includes placing overburden back into the pit, creating shallow water areas and shorelines to provide an irregular appearance, and allowing the pit to fill naturally with water to create additional habitat for birds. The reclaimed pit will be a backup water source for Project purposes.

Exclusive of the Alaska-State C-1 pit, which will be used as a primary water source, water removal from freshwater lakes used by nesting waterfowl will be limited during the summer to minimize the potential for reducing the amount or quality of nesting and brood-rearing habitat through diminished water levels.

Several measures will be implemented to reduce bird strikes. These include:

- Careful consideration will be given to facility lighting (e.g., light hoods to reduce outward-radiating light) that reduces the potential for disorienting migrating birds and reduces bird strikes.
- Buildings and stack heights will be the minimum needed to perform their functions, with consideration for associated footprint. The flares will be free standing (no guy wires).
- The primary Central Pad communications tower will be free standing (no guy wires). The tower will be lighted according to FAA requirements.
- Other communications towers (e.g., at the airstrip or other pads) will avoid the use of guy wires and will be attached to camps or other, larger structures when possible.
- Power lines and fiber-optic cables will either be buried or placed on the pipeline VSMs.
- Aircraft will generally maintain a 1,500-foot altitude to avoid impacts on ground nesting and foraging birds, except as required for takeoff and landing, safety, weather, and operational needs, or as directed by air traffic control.

Gravel placement on the tundra will primarily occur during the winter. Should site preparation and/or construction activities occur during the summer on the tundra prior to July 31 (when most Arctic nesting birds have hatched) the areas in the vicinity of these field activities will be searched for nesting birds by a qualified biologist prior to the start of work. If an active nest of a migratory bird is found (even after July 31), the appropriate USFWS Field Office will be contacted for instructions on how to avoid or mitigate the potential loss of the active nest.

4.8 MARINE MAMMALS

Proposed Project development concerns associated with marine mammals are habitat impact, changes in behavior due to disturbance and activities, and direct impacts such as vessel or vehicle collision or exposure to toxic materials. In this EMR, bowhead whales and seals are discussed separately from polar bears.

4.8.1 Whales and Seals

Because Project activities are primarily onshore, the potential to impact bowhead whales and seals is limited. The activity with the greatest potential for impact is marine vessel traffic. Vessel noise and activity could disturb or deflect whales and seals. Vessel collisions are unlikely, but possible. There is also a potential for noise from pile driving to impact seals.

4.8.1.1 Summary

Key mitigation measures related to bowhead whales and seals will include:

- Minimizing offshore infrastructure.
- Installing mooring dolphins and the Service Pier in winter and in less than 8 feet of water.
- Using Marine Mammal Observers (MMOs) on barges, vessels, and convoys.
- Planning sealift barging to be completed prior to the main fall bowhead whale migration and subsistence whaling.
- Routing coastal barging inside barrier islands.
- Constructing the Service Pier to reduce number of coastal barging trips.
- Implementing applicable protective measures of the Conflict Avoidance Agreement (CAA) with the Alaska Eskimo Whaling Commission (AEWC).
- Constructing ice roads onshore or on the sea ice over shallow waters (grounded ice), avoiding seal habitat.
- Dredging the barge landing area through the ice during the winter preceding an open water sealift, which will minimize disturbance to marine mammals. Maintenance dredging and screeding, if needed in the summer, is expected to be minor.

4.8.1.2 Background Context

The Project is an onshore field development with minimal offshore infrastructure. The primary marine vessel traffic will employ smaller coastal barges traveling between Prudhoe Bay and Point Thomson following a route inside the barrier islands. Larger sealift barges carrying modules will travel outside the barrier islands; these may be used for up to three construction seasons.

Marine mammal species occurring in or near the Project include bowhead and beluga whales; ringed and bearded seals, and polar bears (discussed in Section 4.8.2). Only two (the ringed seal and polar bear) occur there regularly and year-round inshore of the barrier islands. The bowhead and beluga whales occur commonly offshore of the barrier islands during spring and fall migrations. The bearded seal is seasonally uncommon in small numbers and would be unlikely to occur inshore of the barrier islands.

The barge and vessel traffic during the past three summers has given ExxonMobil considerable experience in mitigation of marine mammal impacts. During the 2008 through 2010 coastal barging seasons, MMOs sighted seals and polar bears in the vicinity of the barges; no whales or walrus were observed.

4.8.1.3 Mitigation Measures

Key mitigation measures incorporated to avoid or minimize impacts to bowhead whales and seals are discussed below by Project component.

4.8.1.3.1 Barging

The planned sealift barge route passes outside the barrier islands, after rounding Barrow, and enters Point Thomson area waters through either the Challenge or Mary Sachs Entrance. The sealift transit and offloading operation is planned to be completed prior to fall migration of the bowhead whale, which is also when ringed seals tend to occur farther offshore near the ice edge. The sealift is timed to occur during a period of historically certain open water. The more frequent coastal barging will generally follow a route inside the barrier islands between the Prudhoe Bay West Dock and Point Thomson. The Service Pier mitigates the potential effects of coastal barging by significantly reducing the number of barge runs required by up to 50 percent, as described in Section 4.5.3.1.

MMOs will be present on vessels for barge operations in Arctic and sub-arctic waters. In the event a marine mammal is encountered during a barging operation, the MMO will alert the vessel Captain, who will then make any necessary speed and course alternations to avoid a collision. Such corrections will be taken when whales are within 1 mile of a barge. It should be noted that both sealift and coastal barges run at low speeds (5 to 6 knots), and there are no known collisions in the Alaskan Beaufort Sea between bowhead whales and barges operating at these speeds.

As part of the overall mitigation program, ExxonMobil will implement applicable protective measures of a CAA with the AEWC. Although the CAA primarily relates to avoiding conflicts with subsistence whaling, there are numerous provisions in the CAA that relate to minimizing impacts to marine mammals. Additional information on the CAA is provided in Section 4.14.3.1.

4.8.1.3.2 Offshore Pile Installation

Construction of the Service Pier and mooring dolphins, particularly pile driving, is a source of construction noise and disturbance. However, construction will occur in the winter, on grounded ice, and at a location that will minimize the potential for interactions with ringed seals, which are usually further offshore in floating landfast ice areas. There are eight mooring dolphins and six pilings for the Service Pier, each of which will typically take less than 1 day to install.

4.8.1.3.3 Ice Roads

Ice roads may be located offshore, onshore, or both. They are typically constructed between December and February and operate until tundra travel closure (historically late April/early May). In general, an offshore ice road is routed close to the shoreline and within the 3-meter isobath where the ice is grounded and stable. Such an alignment minimizes the potential for interactions with ringed seals, which are usually further offshore.

4.8.2 Polar Bears

Polar bears frequently come ashore and can be encountered by Project personnel any time of the year. Project activities that could potentially affect polar bears include construction activities such as ice road construction and operation, installation of barge facilities, and grounding barges for offloading. Additionally, spills could potentially affect polar bears, depending on type, size, and location of the spill. Many of the mitigation measures described for terrestrial mammals (Section 4.6) also apply to polar bears.

4.8.2.1 Summary

Mitigation measures specific to polar bears will include:

- Implementing spill prevention and response programs, as described in Section 4.19.
- Implementing and building upon the successful experience of procedures developed during the 2008 through 2011 drilling program (including, but not limited to, measures noted below).
- Obtaining LOAs from the USFWS for Incidental and Intentional Take by Harassment of polar bears.
- Updating and implementing the Project's Polar Bear and Wildlife Interaction Plan.
- Conducting FLIR surveys for potential maternal polar bear dens along ice road routes.
- Implementing procedures and communications protocols for wildlife encounters.
- Closing and rerouting an ice road if an active polar bear den is discovered within 1 mile of the ice road route, or taking other action in consultation with the USFWS
- Conducting ice road closure drills to practice the ice road closure protocols.
- Watching for polar bears using bear monitors and deterring polar bears from Project activities, as necessary, using USFWS-approved deterrent methods.
- Employing operational controls (e.g., road and air traffic restrictions).
- Ensuring Project workers attend appropriate training programs, such as Arctic Pass, which cover polar bear and wildlife awareness.
- Communicating with the workforce on polar bear issues through Environmental Bulletins, posters, safety meeting discussions, etc.
- Developing Project design and operational features to avoid or discourage wildlife encounters and to protect wildlife and human safety (e.g., building walkways and doors, lighting, snow management, and traffic control).

4.8.2.2 Background Context

Polar bears could occur in the Project area any time of the year. Some female bears may den in the Project area in winter, most commonly on or close to the barrier islands or coastline.

As with the drilling program completed in 2010, ExxonMobil will obtain LOAs from the USFWS for Incidental and Intentional Take by Harassment of Polar Bears. The LOAs (for which regulations are currently being re-issued) provide for and require the following conditions, in part:

- The Incidental Take LOA authorizes the taking of small numbers of polar bears incidental to activities.
- The Intentional Take by Harassment LOA authorizes the taking of polar bears by harassment or deterrence by trained and qualified personnel. Harassment or hazing activities must not cause injury or death of a polar bear.

The 3 years of experience gained in building and operating ice roads in the Project area to support the drilling program for PTU-15 and PTU-16 has yielded valuable experience for avoiding and minimizing impacts to polar bears (and from polar bears to humans). Polar bears were encountered onshore during the PTU-15 and PTU-16 drilling program, and numerous special mitigation measures have been developed to protect both the bears and Project personnel. These measures are detailed in the Project's Polar Bear and Wildlife Interaction Plan, and have been recognized by the USFWS and other agency personnel as being responsive to the needs and successful in mitigating potential impacts. These measures, via the Polar Bear and Wildlife Interaction Plan, will be updated and modified, as appropriate, for construction and long-term operations.

4.8.2.3 Mitigation Measures

The mitigation measures described in Section 4.6 for Terrestrial Mammals and in Section 4.8.1 for bowhead whales and seals will also apply to polar bears. Other key mitigation measures incorporated to avoid or minimize impacts to polar bears are discussed below by Project component.

4.8.2.3.1 Ice Roads

The primary potential impact to polar bears from ice roads would be disturbance to female bears during and immediately after the denning period. Polar bears den in snow drifts that vary in location from year to year. Therefore, it is not possible to predict with certainty where a den might be. ExxonMobil's approach has been to detect dens and then to take proactive measures to avoid disturbing them.

The first step in den detection will be to conduct one or more aerial surveys in cooperation with the USFWS using FLIR camera before or shortly after ice road construction commences. If the FLIR survey finds a heat signature that may be indicative of an active den, additional ground level FLIR surveys, or other actions, may be taken to verify the den. Ice roads and other activities will avoid active dens by 1 mile, unless otherwise authorized by the USFWS.

While ice roads are active, security measures and ice road rules will be implemented to avoid and minimize interactions with polar bears and other wildlife. For example, operators are required to report wildlife sightings immediately to the nearest security checkpoint. If such a sighting is a polar bear, then the USFWS will be notified and appropriate actions taken – which may include shutting down the road down. Ice road closure protocols are included in the Polar Bear and Wildlife Interaction Plan. These protocols will be practiced in annual ice road closure drills.

4.8.2.3.2 Project Construction, Drilling, and Operations

During construction, drilling, and operations, bear monitors will watch for polar bears and other wildlife to identify the wildlife as early as possible so that appropriate measures can be taken.

Bear monitors will be used at other construction sites, as needed. No action other than monitoring is required in most cases. All polar bear observations will be reported to USFWS within 24 hours. Bear monitors will be trained in USFWS-taught or approved training courses and will employ deterrence methods, as needed, to keep polar bears away from humans and Project activities. Clear communication protocols have been provided and proven for bear encounters. Every worker will be required to notify the bear monitor, security, or supervisors whenever they see a bear or sign of a bear (e.g., bear tracks or scat). A bear-specific alarm will alert workers when a bear is in the vicinity and that they need to seek safety inside. Other approaches to providing bear warnings may be used, such as radios, intercoms, and lights and placards at exit doors. Hazardous materials and waste, particularly for food, garbage, and sewage, will be stored in bear-resistant containers. Personnel will be strictly prohibited from feeding all wildlife.

4.9 FISH AND FISH HABITAT

Proposed Project development concerns associated with fish are maintenance of feeding, spawning, and overwintering habitats and allowing free passage to and from these areas. Project activities that could impact these include water withdrawal, alteration of flow patterns through placement of fill, spills, and alteration of water quality.

4.9.1 Summary

Key mitigation measures related to fish and fish habitat include:

- Minimizing impact to natural stream flow conditions through application of hydrology study results to bridge and culvert design using conservative criteria.
- Constructing ice roads in a manner that protects fish habitat and slotting ice roads at designated stream crossings at the end of the season.
- Limiting lake withdrawal volumes and using proper withdrawal methods to protect fish.
- Implementing a tracking systems including coordination with other water users to ensure water withdrawal limitations are met.
- Maintaining natural stream flow through the design of bridges and culverts to accommodate fish passage.

4.9.2 Background Context

The Project streams and lakes in the immediate Point Thomson area provide limited habitat for anadromous fish. Resident fish (e.g., stickleback) are believed to exist throughout the Project area. Several species of fish migrate close to shore off the Central Pad. The results of 2010 summer marine fish studies near the Central Pad, which updated earlier studies, have been provided to the USACE, Cooperating Agencies, and third-party EIS consultant, as well as the NSB and Kaktovik.

ADF&G and ADNR manage temporary and permanent water withdrawals from surface water in fish-bearing waterbodies. Cumulative water withdrawals from multiple users are not allowed to reduce the water below the level necessary to support anadromous and resident fish. Water withdrawal limits are established to allow sufficient volumes of water to remain in lakes under ice through late spring for overwintering fish. ADF&G requires that water withdrawal intake

structures in fish-bearing waters be designed, operated, and maintained to prevent fish entrapment, entrainment, or injury, unless specifically exempted by ADF&G.

ADF&G requires a Title 16 permit for installation of bridges and culverts at stream crossings to ensure they are designed to maintain adequate flow and allow fish passage. Before permits are issued, ADF&G evaluates stream location, gradient, depth, width, construction methods, hydraulic data, potential channel changes or increase in bank erosion, and presence and type of fish within the stream.

4.9.3 Mitigation Measures

The Project has been designed to maintain stream flow conditions that provide adequate passage for fish and suitable water quality, as described in Section 4.4. Adequate flow/volume must remain to support indigenous aquatic life, and the watercourse must not be blocked to the passage of fish.

As described in Section 4.3.2, roads have been routed to minimize stream crossing impacts, including fish habitat. Stream crossings will meet applicable ADF&G criteria for fish passage. Bridge and culvert designs have been reviewed with ADF&G, and design modifications have been made to accommodate fish passage, as discussed in Sections 4.3.3.2, 4.3.3.3, and 4.3.3.4. In particular, two stream crossings (Streams 18A and 24A) will have a hybrid culvert design consisting of line pipe to provide structural integrity and a single corrugated multi-plate culvert installed along the thalweg of the stream to accommodate fish passage.

The temporary barge-bridge system will have 60- to 80-foot spaces between the barges and between the first barge and the shore. This spacing will allow for fish passage. Further, the barge-bridge system is temporary – in place for the minimum time period needed to complete offloading (an estimated 2 to 4 weeks) for up to three sealift/construction open water seasons. The Service Pier is a pile-supported structure that will allow normal water flows and not impede fish movements.

No bridges are required for the in-field or export pipelines. Where practicable, pipeline VSMs will not be installed in the active channel of streams.

Stream banks will not be cut for access during construction activity and ice or snow ramps will be constructed, if required, for ice road stream crossings – thus maintaining the integrity of existing stream banks and protecting stream water quality. Major construction efforts will be conducted primarily in winter for infield roads, pads, pipelines, and the airstrip.

Winter water withdrawal in fish-bearing water sources will be limited to permitted methods and quantities to protect fish overwintering habitat, as described in Section 4.9.2. ExxonMobil also has a number of general requirements for managing water withdrawal to protect the waterbody, fish habitat, and the surrounding environment. These requirements include:

- Monitoring water withdrawal volumes. A log is kept to track water volume by source. When the withdrawal volume approaches 90 percent of the permitted water volume, use of the source is stopped as a contingency to ensure appropriate water volumes remain.
- Tracking. A water use preplanning chart is used to identify water withdrawal lakes and locations for use in ice road construction. This assists in confirming there is enough water in strategic locations to support construction activity. A dispersing log will be kept

in the field to track water sources and use information, including coordination with other water users, to ensure water withdrawal limitations are met.

- Recharge monitoring. Annual recharge monitoring is currently required for the Shaviovik Pit to accommodate modified water withdrawal volume. The Alaska State C-1 Pit has been monitored in the past couple years to confirm it recharges since it is a primary water source. Monitoring has indicated that both pits have recharged completely following each breakup.

To further protect freshwater habitat in rivers, ice roads are constructed as described in Section 4.2.3.9. Prior to breakup, the ice road will be slotted at designated stream crossings to mitigate alteration of breakup water flow in stream channels.

4.10 AIR QUALITY

Proposed Project development concerns associated with air quality are increased pollutant emissions and dust.

4.10.1 Summary

To minimize potential effects on air quality, ExxonMobil designed the Project and its activities to reduce potential emissions and, in some areas, to exceed the minimum Clean Air Act requirements under the Prevention of Significant Deterioration (PSD) Construction Permitting Program. Key mitigation measures related to air quality include:

- Using state-of-the-art Tier IV off-road and stationary engines for drilling and construction activities for Nitrogen Oxides (NO_x) control.
- Implementing Best Available Control Technology (BACT) for stationary emission units, including Dry Low NO_x (DLN) combustors on the turbines.
- Using electric-powered injection compressors.
- Using Waste Heat Recovery Units (WHRUs) for dual-fired turbines.
- Using natural gas for the primary and emergency fuel systems, thus reducing the need for diesel fuel.
- Designing production gathering lines for full wellhead shut-in pressure of the wells, thus avoiding potential vent/relief valve emissions.
- Using state-of-the-art incinerator units meeting requirements of newly released 40 CFR 60 Subpart CCCC.

4.10.2 Background Context

The criteria pollutants that will be emitted in quantities greater than the PSD permit applicability thresholds are:

- NO_X
- Carbon monoxide (CO)
- Fine fraction respirable particulate matter ($PM_{2.5}$)
- Greenhouse gases

Small amounts of coarse fraction particulate matter (PM_{10}) and sulfur dioxide (SO_2) (below PSD applicability thresholds) will also be emitted.

As part of the PSD permitting process, an air quality analysis, including dispersion modeling, was prepared to demonstrate compliance with all applicable ambient air quality standards and increments. This dispersion modeling was conducted using EPA- and Alaska Department of Environmental Conservation (ADEC)-approved dispersion models. This modeling will also use hourly meteorological data collected at Point Thomson. Baseline ambient air pollutant measurements collected at Point Thomson were incorporated into the modeling results.

4.10.3 Mitigation Measures

ExxonMobil designed the Project and its activities to reduce emissions and to minimize the Project's potential effects on air quality. BACT analyses was done for all stationary emission units, evaluating state-of-the-art methods, systems, techniques, and production processes to achieve the greatest practicable reduction in air pollutants emitted. Technology determined to be BACT will be installed. Natural gas produced at the site will be the primary fuel source during production, which reduces greenhouse gas emissions. Where diesel-fired reciprocating engines must be used, these engines will be compliant with the emission limits and other requirements of the applicable New Source Performance Standard (NSPS), 40 CFR 60, Subpart IIII, Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. Additionally, all diesel-fired equipment, both stationary and mobile, will combust ultra-low sulfur diesel (ULSD). Stationary and off-road diesel engines for drilling and construction will be equipped with Tier IV NOx controls.

4.10.3.1 Turbine Emissions

The largest air pollutant emission sources for the Project will be the four gas/dual-fired turbine driven electric power generators (GTGs). Using turbines to generate electricity, and then using electric motors (especially the gas re-injection compressors), significantly reduces the overall pollutant emissions from the site versus the alternative of using diesel-fired engines to drive equipment. The pollutant emission reduction measures on the GTGs themselves will include:

- Installing DLN combustors with inlet air heating on each GTG to enable operation of the DLN combustors at ambient temperatures less than 0 degrees Fahrenheit, optimize combustion and reduce NO_X and CO emissions.
- Installing a post-combustion catalytic oxidation system on each GTG to reduce CO and volatile organic compound (VOC) emissions by 90 percent and 70 percent, respectively.

4.10.3.2 Engineering Design

The use of WHRUs will result in an overall reduction of facility air emissions. These units will be installed on two of the four GTGs. The WHRUs will provide needed process and space heating, and eliminate the need for separate gas-fired boilers and heaters, thus reducing fuel consumption and air emissions.

Another improvement is the planned inclusion of an emergency fuel gas system supplied from a connection to the Central Pad gas injection well. Use of this fuel gas supply will reduce the need to use diesel fuel during periods when the production operation is shut down and essential power must continue to be provided to the facilities and camp.

The Project design for the production gathering lines provides for full wellhead shut-in pressure of the wells. This allows the wells to be shut-in at the Central Processing Facility during process upsets, or other times when it is necessary, in a manner that safely contains the produced fluids within the wells and gathering lines. This avoids the need to install pressure relief devices that would vent hydrocarbons to prevent overpressuring the lines, thereby reducing the amount of greenhouse gases that must be vented for safe operations.

4.10.3.3 Operations

Operational controls or measures to mitigate impacts will include maintaining equipment in accordance with manufacturer's recommendations. This will ensure the emissions control equipment continues to operate as intended.

Other operational controls to manage dust will include road and pad watering and enforcing speed limits. Parking areas will have power outlets for maintaining vehicle starting reliability during low ambient temperatures and to reduce the need for extended periods of idling.

4.11 LAND OWNERSHIP, LAND USE, AND LAND MANAGEMENT

Proposed Project development issues associated with land ownership, land use, and land management are the issuance of permits and consultations with land owners adjacent to the Project (e.g., Native Allotments).

4.11.1 Summary

Key mitigation measures related to land ownership, land use, and land management will include:

- Consulting with land owners or managers within or adjacent to the Project area, including the U.S. Department of the Interior (Arctic National Wildlife Refuge [Arctic Refuge]), U.S. Department of Defense (U.S. Air Force [USAF]; Bullen Point), ADNR, NSB, Iñupiat Community of the Arctic Slope (ICAS), community of Kaktovik, and Native Allotment owners/heirs.
- Ensuring Project activities do not encroach upon Native Allotments or Traditional Land Use sites through survey and demarcation.
- Facilitating traditional uses of the Project area.

4.11.2 Background Context

ADNR is the primary landowner in the Project area. ADNR leased the area for oil and gas exploration and production, and the Project is consistent with ADNR's plans for the area.

The federal government owns land in the Bullen Point Radar Site and the Arctic Refuge. Depending upon chosen transportation routes, the Bullen Point Radar Site may be adjacent to, or crossed by, Project ice roads and tundra travel routes. The USAF manages the Bullen Point Radar Site and approval is required for access. The western boundary of the 1002 Area of the Arctic Refuge is located about 2 miles east of the proposed East Pad and approximately 6 miles east of the proposed Central Pad. The Wilderness Area of the Arctic Refuge is approximately 30 miles from both the Central and East Pads.

The Point Thomson Unit has been zoned by the NSB as a Resource Development District, a designation which allows for large-scale resource development.

Several private landowners of Native Allotments exist near the Project area.

4.11.3 Mitigation Measures

Key mitigation measures incorporated to avoid or minimize impacts to land ownership, land use, and land management are discussed below. Mitigation measures specific to subsistence and other traditional uses of the Project area are discussed in Section 4.14.

4.11.3.1 State Land

ADNR has leased the Project area for oil and gas exploration and development, and the Project is consistent with ADNR's management of the area. The Project is expected to be consistent with applicable ADNR lease sale stipulations and mitigation measures. State permitting costs are reimbursed by ExxonMobil through fees and Reimbursable Service Agreements to the extent allowed by law and regulation.

4.11.3.2 Federal Land

The USFWS manages federal land in the Arctic Refuge. ExxonMobil has considered potential Project impacts of oil and gas development on land use. Mitigations developed for avoiding or minimizing impacts to recreation and visual aesthetics (Sections 4.15 and 4.16, respectively) also provide mitigation for potential impacts to land use in the Arctic Refuge.

4.11.3.3 North Slope Borough

As noted above, the Project is fully consistent with the NSB's land management objectives for the area. The Project will require approval of a Master Plan, rezoning a portion of land for the PTEP, and administrative or development permit approvals, thereby further assuring project consistency with NSB policies. Through a permit fee structure, the NSB receives revenue to offset associated administrative costs.

4.11.3.4 Native Allotments

ExxonMobil has been proactive in avoiding impacts to Native Allotments, and none of the Project activities are located on Allotments. ExxonMobil has established regular communication with the area's Native Allotment owners/heirs to keep them apprised of Project activities. When Project operations occur in proximity to an allotment, extra measures will be taken to avoid access and/or impacts to these private lands. These include surveying and staking the allotments and installing signs or taking other measures to ensure Project workers do not trespass onto the allotments.

4.12 SOCIOECONOMICS

A major ExxonMobil objective for the Project is to provide positive social and economic benefits from the Project. Positive socioeconomic impacts from Point Thomson include increased employment and contracting opportunities for North Slope and other Alaska residents and businesses, as well as increased tax revenue for local and state governments. Adverse impacts could include disruption of community characteristics or culture, interference with existing

businesses that results in a loss of existing jobs, and reduced income leading to a decreased tax base.

4.12.1 Summary

Key mitigation measures related to socioeconomics will include:

- Providing employment opportunities for North Slope and other Alaska residents.
- Providing contracting and business opportunities for North Slope and other Alaska companies.
- Generating revenue for the State and NSB governments.
- Making contributions and providing other support for local schools, social, and cultural needs.

4.12.2 Background Context

The Project is located within the NSB. Due to the distances, local communities have not been, nor are likely to be, used to provide housing or other direct support to the Project. Both Kaktovik and Nuiqsut have established for-profit village corporations under the Alaska Native Claims Settlement Act (ANCSA), which have income opportunities associated with the Project.

ExxonMobil provided significant socioeconomic benefits for North Slope corporations and residents during the PTU-15 and PTU-16 drilling program. An *Economic Opportunity Plan* was developed for the drilling program that outlined potential economic opportunities for NSB residents and businesses. The *Economic Opportunity Plan Report 2009-10* documented the activities completed under that plan. The following summarizes those activities and associated benefits and is presented as an example of the type of benefits expected from the proposed Project.

The Kaktovik and Nuiqsut village corporations were employed to provide services for the PTU-15 and PTU-16 drilling program and were among the Project's largest contractors when measured in terms of revenue. Fifty-five North Slope residents were employed in direct and support positions for the drilling program. Local residents were particularly important in fulfilling roles such as MMOs on marine vessels, Bear Monitors, and Subsistence Representatives – which brought traditional knowledge to the field operations and also provided communication links back to the communities.

ExxonMobil has sponsored an annual career/job fair in Kaktovik to encourage local employment and training and plans to continue this into field construction and operations.

4.12.3 Mitigation Measures

A primary mitigation measure is providing contracting and employment opportunities, ExxonMobil will also support NSB and Alaska residents in various ways. For example, support for schools and education has included providing technical personnel via an ExxonMobil Science Ambassadors program, making financial contributions, raising funds, and donating equipment and supplies.

Details on the potential future economic benefits to the NSB and ExxonMobil's activities and plans to maximize those benefits through local contracting will be described in an *Economic*

Opportunity Plan included with ExxonMobil's *Point Thomson Resource Development District Master Plan*, which will be submitted to the NSB in compliance with Title 19 of the NSB Land Management Regulations.

4.13 CULTURAL RESOURCES

Proposed Project development concerns associated with cultural resources include potential impact to cultural resources in the Project area, reducing their cultural significance and heritage value, and potentially resulting in a loss of information about the past.

4.13.1 Summary

The primary mitigation to avoid or minimize potential impact to cultural resources is preparation and implementation of a comprehensive *Point Thomson Cultural Resource Management Plan* (CRMP), which includes the following:

- Field and literature surveys to identify all cultural resources in the Project area.
- Interviews with local elders and others knowledgeable about potential resources.
- Development of protocols to protect sites that are known or discovered during Project construction or operations.
- Effective training for the workforce on the importance of protecting cultural sites and proper procedures to do so.

4.13.2 Background Context

Numerous site-specific and general archaeological surveys have focused on identifying cultural resources in the Point Thomson area. ExxonMobil recognizes the importance of cultural resources to the State of Alaska, the NSB, and communities that are near the Project.

4.13.3 Mitigation Measures

A comprehensive CRMP has been prepared for the Project. The primary objective of the CRMP is to protect cultural resource sites (and new sites discovered as a result of the Project) and, thus, their cultural significance and heritage. This Plan was submitted to the NSB, Iñupiat History, Language, and Culture (IHLC) Commission, and State Historic Preservation Office (SHPO) prior to its submittal to the USACE to initiate the formal Section 106 process, as required by the National Historic Preservation Act.

The CRMP includes: a compilation and analysis of existing data from prior cultural resource investigations in the Project area; a review and summary of data relevant to Traditional Land Use Inventory in the Project area; and 2007, 2008, and 2009 field data that update the condition of cultural resource sites. Extensive cultural resource reconnaissance surveys have been conducted in the Project area in the past. A few historic/prehistoric sites were discovered during those investigations, and two new small prehistoric sites were documented in 2009. For the CRMP, the known sites were revisited, their condition documented, and their relationship to the Traditional Land Use Inventory sites assessed. The cultural resource potential of the entire Project area was evaluated, and designated into areas of high, moderate, and low potential for cultural resources to guide current and future project planning.

The CRMP provides the basis to avoid known sites, develop and implement a protocol for documenting new sites discovered within the Project area, and provide effective cultural sensitivity training for Project workers. Such training is important to ensure workers understand the importance of protecting cultural sites to avoid incidental or inadvertent damage to them.

4.14 SUBSISTENCE AND TRADITIONAL LAND USE PATTERNS

Project development activities have the potential to affect local residents who use the Project area for subsistence purposes, or who harvest resources that migrate through the Project area.

Avoiding or reducing impacts to subsistence is an ExxonMobil priority. An extensive consultation program with the NSB and Kaktovik (approximately 60 miles to the east, the Project's closest community) is ongoing and will continue, as supported by the community, for the life of the Project. This consultation program has also included Nuiqsut and other North Slope entities, such as ICAS and the AEWC. A focus of these consultations has been to address and mitigate issues of local concern regarding Project design, construction, and operations. ExxonMobil supports continuation of traditional subsistence hunting and fishing activities in the Project area. Mitigations to protect wildlife resources typically also protect subsistence. Other measures to mitigate impacts to subsistence are summarized below.

Additional details on ExxonMobil's activities and plans to mitigate impacts are described in the Subsistence chapter included in *ExxonMobil's Point Thomson Resource Development District Master Plan* to be submitted to the NSB, in compliance with Title 19 of the NSB Land Management Regulations.

4.14.1 Summary

The key mitigation measures related to subsistence and traditional land use patterns will include:

- Routinely consulting with subsistence users to understand current and changing subsistence activities and patterns, identifying impacts that may have occurred, and ways to prevent reoccurrence.
- Employing local Subsistence Representatives during active construction and drilling.
- Continuing to inform nearby Native Allotment owners/heirs, AEWC, and tribal organizations of Project activities that may affect subsistence use or access to subsistence resources or traditional use sites.
- Implementing applicable protective measures of the CAA with the AEWC and Kaktovik and Nuiqsut Whaling Captains' Associations, which include support of Communications Centers (Com Centers) for improved communications and safety during periods of marine activity.
- Avoiding interference with bowhead whales during the fall migration period by designating preferred routes inside the barrier islands for coastal barging and planning to complete sealift barging prior to the fall migration.
- Conducting marine activities prior to or after the Kaktovik and Nuiqsut fall bowhead whale subsistence hunts, unless other arrangements are made (as described in Section 4.14.3).
- Using MMOs for marine vessels as provided in the CAA.

- Developing protocols and designing pipelines to facilitate the continuation of current hunting patterns.
- Requiring routine aircraft flights (e.g., transportation of personnel and cargo) to generally fly at a 1,500-foot altitude following a path inland from the coast to avoid disturbance to wildlife and subsistence activities, except as required for takeoffs and landings, safety, weather, and operational needs, or as directed by air traffic control.
- Providing emergency assistance to subsistence hunters and other community residents traveling through the Project area, in cooperation with Kaktovik Search and Rescue or by NSB Search and Rescue.
- Developing guidelines in cooperation with the community on safe hunting in proximity to oilfields.
- Designing the PTEP to withstand accidental bullet strikes from coastal hunters.
- Making subsistence-related training mandatory for the North Slope-based Project workforce, including protection of subsistence resources, lands, wildlife, and cultural and archaeological awareness as part of Arctic Pass training.
- Prohibiting hunting and fishing by ExxonMobil employees and contractors while personnel are assigned to, and working in, the Point Thomson area.
- Designing Project features (e.g., color, lighting schemes, and buried/suspended cables) to minimize visual impact to subsistence users and resources.
- Implementing dust control BMPs to minimize impacts of dust fallout onto terrestrial and aquatic habitat.
- Implementing the *ExxonMobil Point Thomson Project Oil Spill Contingency Mitigation Agreement* (Mitigation Agreement), with $25 million in funding currently in place to provide immediate assistance to subsistence communities and users in the event of a spill preventing access to subsistence resources.

4.14.2 Background Context

ExxonMobil recognizes that subsistence is at the core of cultural values and well-being of the Iñupiat people, and that the Point Thomson area is important to residents of Kaktovik and Nuiqsut for subsistence activities and resources. ExxonMobil is committed to avoiding impacts to subsistence and facilitating continued subsistence activities in the Point Thomson area.

4.14.2.1 Community Outreach

ExxonMobil's approach toward meeting Project commitments is to better understand subsistence uses and obtain input to help avoid impacts. Effective and consistent consultation with North Slope constituents will help ensure their concerns are identified and addressed in a timely and appropriate manner.

In 2008, ExxonMobil began formal consultation with NSB government entities and residents on the current Project's drilling and production facilities plans. ExxonMobil has consulted extensively with a broad range of North Slope stakeholders, including the NSB, communities of Kaktovik and Nuiqsut, ICAS, AEWC, and Native Allotment owners/heirs, on the design and progress of the Project. ExxonMobil is involved in ongoing initiatives to communicate with local residents about the Project.

4.14.2.2 Subsistence Resources

The subsistence resources that might be hunted by local residents include marine mammals, terrestrial mammals, and waterfowl. Subsistence fishing is also a factor. Bowhead whales and other marine mammals transit the marine environment offshore of the Project area. The bowhead whale is the main resource harvested by Kaktovik and Nuiqsut for subsistence, primarily during the fall. In addition to the subsistence mitigation measures described below, the project has incorporated mitigation measures specifically addressing marine mammals, as discussed in Section 4.8.

Caribou are also vitally important to subsistence hunters. Caribou transit the Project area and may be hunted by Kaktovik residents from the coast in the summer. In addition to the subsistence mitigation measures described below, the project has incorporated mitigation measures specifically addressing terrestrial mammals, as discussed in Section 4.6.

4.14.3 Mitigation Measures

Key mitigation measures incorporated to avoid or minimize impacts to subsistence are discussed below. These operational measures and commitments to protect subsistence have been implemented during the recent drilling phase and will continue during construction and operations of the proposed Project.

4.14.3.1 Barging Conflict Avoidance Agreement

ExxonMobil will continue to sign an annual CAA and adhere to its provisions to avoid and minimize potential impacts from marine activities on subsistence whaling activities, including providing support for the Deadhorse and Kaktovik Com-Centers when marine activities will occur. ExxonMobil will conduct marine activities to and from the Point Thomson area prior to the Kaktovik and Nuiqsut fall bowhead whale subsistence hunts and will not resume marine activities until the Kaktovik and Nuiqsut Whaling Captains report that their hunt has concluded, unless other arrangements are made in consultation with the Whaling Captains and AEWC. Marine requirements are expected to be much greater during project construction phases. ExxonMobil will adhere to CAA terms to avoid and minimize impacts and will also coordinate its activities with the AEWC and Kaktovik and Nuiqsut Whaling Captains.

Point Thomson Project activities comprise operation of barges and transit vessels in the Beaufort Sea under Titles II and III of the current CAA.

Under Title II, MMOs are stationed on each lead vessel of a tug/barge group transiting the Beaufort Sea to keep watch for marine mammals and log all sightings. Com Centers, funded by industry participants, will coordinate between industry vessels and subsistence whalers to avoid subsistence impacts and facilitate emergency assistance. In addition to observing marine mammals, the MMOs communicate industry vessel locations, speed, and direction to the Com Centers.

The CAA requires vessels to maintain speeds necessary to ensure no physical contact with whales occurs, and to make other potential conflicts with bowhead whales or whalers unlikely. Precautions (e.g., speed limits) are included to avoid potential interactions with the whales. Efforts are made to steer around whale groups without separating them or causing the whales to change direction.

4.14.3.2 Oil Spill Contingency Mitigation Agreement

The Mitigation Agreement is a commitment by ExxonMobil to make funding immediately available to subsistence users and communities in the unlikely event of a marine spill that prevents access to subsistence resources. The Mitigation Agreement was established prior to drilling the Point Thomson PTU 15 and PTU-16 wells in 2009 and 2010 and remains in place. In addition to ExxonMobil, it has been approved and signed by the NSB, AEWC, and City of Kaktovik. Other North Slope communities and organizations will be invited to join the Mitigation Agreement, as appropriate.

The key innovative features of the Mitigation Agreement include:

- The Mitigation Agreement establishes a $25 million fund to aid subsistence users in the event of a marine spill that prevents access to subsistence resources. This is based on a $25 million letter of credit currently in place at Wells Fargo Bank.
- The Mitigation Agreement does not require an extended process to determine whether access to the fund should be permitted. Instead, in the event of a spill and a request for assistance from the Mayor of Kaktovik, or another affected community, the NSB is authorized to appoint an administrator to address claims and make payments. Upon notice to the bank by ExxonMobil of the name of the Administrator, the Administrator can immediately access the $25 million letter of credit to make payments to individuals, as needed, for a variety of mitigation measures. No approval or other action by ExxonMobil is required. Activating the fund is intended to be as expeditious as possible.
- The $25 million fund is not a ceiling or a substitute for other methods of claims or payments, but is intended to provide money which is immediately available if needed.
- The fund can also be used to address longer term impacts that are identified within3 years and reduce availability of bowhead whales or other species harvested by subsistence users.

4.14.3.3 Community Consultation

ExxonMobil will continue consulting with Kaktovik, Nuiqsut, and the NSB about construction and drilling plans, facilities, and operations, with the objective of avoiding and minimizing adverse effects on subsistence. This will focus on community leadership and the Kaktovik Oil and Gas Liaison. A key element of the consultation process has been formation of the Kaktovik Point Thomson Working Group, with the intention to meet regularly to advise ExxonMobil on measures to mitigate impacts through Project design, construction, and operations.

To the extent desired by Kaktovik residents and leadership, consultation during drilling, construction, and operations will remain robust and include the following opportunities:

- Summer and winter community meetings.
- Regular meetings of the Kaktovik Point Thomson Working Group, which has been formed to facilitate communication during the life of the Project.
- Regular communication with the area’s Native Allotment owners/heirs.
- Regular briefings and site visits with North Slope leadership.

Consultations have also included meetings with community members and leadership of Nuiqsut (located approximately 120 miles west of the Project). Continued engagement with Nuiqsut will be guided by community leaders and based on community interest. Additionally, ExxonMobil will keep nearby Native Allotment owners, AEWC, and tribal organizations informed of Project activities that may affect subsistence users or access to subsistence resources or traditional use sites.

ExxonMobil will support subsistence access to the Project area and, in consultation with Kaktovik, will develop guidelines on safe hunting near Project facilities. Emergency assistance will be available to subsistence hunters and other community residents traveling through the Project area, in cooperation with Kaktovik Search and Rescue or by NSB Search and Rescue. As with other Alaska North Slope industrial facilities, public access will be managed to ensure public and facility safety and security.

4.14.3.4 Project Design

ExxonMobil has incorporated mitigation measures into the Project design to avoid or minimize impacts to subsistence and traditional land-use patterns. An important element of project design has been to minimize impact to the visual aesthetics of the area. Main facility color selection will be made in the detail design stage with input from Kaktovik and other stakeholders. External lighting will be selected and North Slope practices will be implemented to reduce or minimize the effects of lighting (e.g., light hoods to reduce outward-radiating light). The selection of external lighting addresses site security and safety requirements, while reducing wildlife attraction and visual impacts. An in-depth lighting study is planned during detailed design, which will address additional light mitigation. Other measures include burying power cables or placing cables on VSMs to eliminate overhead lines and associated visual impacts, and rounding pad corners to reduce profile and possible effects on caribou movement.

Pipelines in general, and the PTEP in particular, have received significant attention in mitigating subsistence impacts. Associated measures will include selecting texture and coating of the PTEP and gathering lines to reduce glare and contrast. The outer jacket of the PTEP and gathering lines will be a dull, grey metallic surface (bonderized stainless steel jacket) to avoid a bright, reflective “visual barrier” and reduce the visual impact on hunters and caribou. The PTEP wall will be thickened, where necessary, to provide protection against incidental bullet strikes from coastal hunters. The gathering lines are designed to contain full well shut-in pressure, and are thick enough so no additional allowance for protection against bullet strikes is necessary.

The PTEP and gathering lines will be installed on VSMs with a minimum 7-foot height above tundra, including vibration dampeners or cables, to allow free passage by caribou and subsistence hunters on snow machines.

The limited marine infrastructure will also reduce subsistence impacts on coastal subsistence hunters. Additionally, the barge mooring dolphins and Service Pier pilings will have reflector tape or lighting to reduce the potential for collisions by North Slope resident’s boats during summer and by snow machines during winter.

4.14.3.5 Construction, Drilling, and Operations

ExxonMobil has implemented, and commits to continue, several long-term mitigation measures to avoid and minimize impacts on subsistence during construction, drilling, and operations.

Subsistence Representatives from Kaktovik, or other North Slope communities, will be hired during periods of active construction or drilling operations to help ensure current subsistence practices are known and Project activities do not interfere with them. Use of Subsistence Representatives during long-term operations will be evaluated during the operational planning phase.

Training will be mandatory for the North Slope-based Project workforce to ensure they understand: the importance of subsistence; the need to protect subsistence resources, lands, and activities; wildlife protection; and the importance of Project workers not interfering with subsistence activities. Hunting and fishing by ExxonMobil employees and contractors will be prohibited while personnel are assigned to and working in the Point Thomson area.

To avoid disturbing subsistence hunting activities, routine aircraft flights (e.g., transportation of personnel and cargo) will generally fly at a 1,500-foot altitude following a path inland from the coast to avoid disturbance to wildlife, except as required for takeoffs and landings, safety, weather, and operational needs, or as directed by air traffic control.

4.15 RECREATION

Potential Project development concerns associated with occasional recreation use of the Project area and areas of the Arctic Refuge east of the Project area include potential disturbance from the presence of facilities, noise, and visual impacts that may result in changes in the recreational experience. It should also be noted that the presence of Project personnel and logistical capabilities may have potential health and safety benefits to recreation users in the event of an accident or bad weather.

4.15.1 Summary

The primary Project and facilities design, construction, and operations features that mitigate potential effects to recreation in the Project area include:

- Mining gravel with blasting, installing offshore mooring dolphins and pilings, and constructing off-pad pipelines during winter when visitation to the Project area and the Arctic Refuge is at the lowest level.
- Designing project features to reduce offsite visual impacts, as described in Section 4.16.
- Designing project features to reduce offsite effect of noise, as described in Section 4.17.
- Implementing aircraft flight path and height protocols to minimize coastal effects associated with noise and visual impacts of aircraft.

4.15.2 Background Context

While designated by the State for development of oil and gas, occasional recreation use of the Project area may occur, primarily during the summer through access to the coastline by boat. Recreation and sport hunting activities associated with floating the Canning River in the Arctic Refuge also occur. As reflected in the USFWS *Public Use Summary, Arctic National Wildlife Refuge* (April 2010), Table 2, floating recreation activities are significantly greater in the upper Canning River-Marsh Fork areas, which are not impacted by the Project, than in other areas of the lower Canning River closer to the Project area. The closest takeout point for float trips on

the Canning River is located approximately 11 miles southeast of the Project area (see Figure 1).

4.15.3 Mitigation Measures

Construction of pipelines, gravel mining, and placement of mooring dolphins for sealift and coastal barge facilities will primarily be done during winter when visitation to the Project area and Arctic Refuge is at the lowest level.

Aircraft operational flight altitudes and approach procedures will reduce disturbance to coastal recreation activities. The airstrip is located about 3 miles inland from the coast and away from areas where occasional recreation use of the Project area may occur. Aircraft will generally fly at a 1,500-foot altitude and inland from the coast. Project design features to reduce offsite visual impacts and effects of noise are described in Sections 4.16 and 4.17, respectively.

Public access to the general Point Thomson area will not be excluded. However, as with other North Slope industrial facilities, public access will be managed to ensure public and facility safety and security. Visitors to the Point Thomson facilities will be required to check-in at the Point Thomson security checkpoint.

4.16 VISUAL AESTHETICS

The primary development concern associated with visual aesthetics of the Project area is adding man-made features to the landscape.

4.16.1 Summary

Key Project mitigation measures associated with visual aesthetics include:

- Designing the lighting on pads to reduce off-pad and distance effects.
- Painting Project facility buildings a color that reduces offsite visual effect.
- Designing buildings and stacks as the minimum needed to perform their functions.
- Burying power lines and fiber-optic cables, or placing them on pipeline VSMs.
- Texturing and coating pipelines and gathering lines to reduce glare and contrast.

4.16.2 Background Context

Use of the Project area by the public is largely limited to local resident use for subsistence, and related mitigation measures are addressed in Section 4.14.3. However, ExxonMobil is cognizant of potential visual impacts that may be brought about by the Project. Related issues presented during Scoping include potential effects of construction and operations on the visual environment. Sensitive viewing points include locations used by visitors to the Arctic Refuge and North Slope residents hunting in or passing through the Project area.

4.16.3 Mitigation Measures

ExxonMobil has instituted a number of Project design and construction/operational procedures to avoid or minimize potential visual impacts, including structure height, color, and lighting. Key elements of visual impact mitigation are discussed below.

Project design has actively pursued and implemented design changes to consolidate facilities and minimize gravel footprint (e.g., use of existing pads, single flare stack for both low pressure and high pressure flares, shortened flare line, consolidated maintenance building, and combined control room into the camp). Pads have been located to allow development of offshore portions of the reservoir from onshore locations, thus avoiding placement of drilling structures in marine waters. The corners of some gravel pads will be rounded to reduce the visual profile.

Project facilities and buildings on pads will typically be painted a color that reduces potential visual effect. Main facility color selection will be made in the detail design stage with input from Kaktovik and other stakeholders. External lighting will be selected and North Slope practices will be implemented to reduce or minimize the effects of lighting (e.g., light hoods to reduce outward-radiating light). The selection of external lighting will address site security and safety requirements, while reducing wildlife attraction and visual impacts. An in-depth lighting study is planned during detailed design to address light mitigation.

Power lines will be buried in the gravel infrastructure or tundra or placed on VSMs to eliminate overhead lines and associated visual impacts. Mitigation associated with the pipeline coatings is discussed in Section 4.14.3.4.

Construction of pipelines, gravel mining, and placement of gravel infrastructure (such as roads and pads) will primarily be done during winter when visitors to the Arctic Refuge, and subsistence activities in the area, are at lower levels of activity.

ExxonMobil will seek use of the Badami communications infrastructure to minimize the number of radio/microwave towers. Intra-facility and well pad communications will be by fiber optic cable to minimize the number of tower structures.

ExxonMobil conducted a visibility screening assessment of the Arctic Refuge based on the potential Point Thomson emissions using a Tier II VISCREEN assessment. Although the Arctic Refuge is designated Class II air shed, the air assessment results indicate that none of the Class I area criteria are exceeded inside the target area.

4.17 NOISE

Proposed development concerns associated with noise are type, magnitude, and frequency of noise generated during construction, drilling, and operations. Information on mitigating noise impacts to marine mammals (e.g., bowhead whales and seals) is provided in Section 4.8.1.3.

4.17.1 Summary

Key Project mitigation measures associated with noise include:

- Installing turbine exhaust silencers of necessary length to provide calculated sound mitigation.
- Installing silencers on turbine combustion air inlet filters.
- Installing low-noise electrical generators for power generation package.
- Installing low-noise design for cooling medium air cooler.
- Installing acoustic panels on some module interior walls.

- Installing noise enclosures around the instrument air compressors.
- Installing noise enclosures around turbines.
- Installing hospital grade silencers on the diesel engines driving the camp standby power generation packages and the emergency fire suppression packages.
- Performing major construction activities in the winter to minimize impacts on sensitive receptors.

4.17.2 Background Context

Project-related noise is important from an environmental impact analysis perspective, as well as worker safety. ExxonMobil has conducted a facility noise study during Front End Engineering Design (FEED). The noise emissions from the Central Processing Facility were modeled using SoundPLAN 6.5, which is a certified noise analysis computer model compliant with ISO 9613, Part 2. The purpose of the study was to conduct a noise sensitivity analysis to facilitate selection of noise mitigation measures appropriate for the Project, and to predict sound pressure levels within the facility, as well as at the edges of the Central Pad and beyond.

4.17.3 Mitigation Measures

ExxonMobil will include intrinsic noise characteristics (i.e., sound power) into key equipment criteria when selecting vendors for noise-emitting equipment. Based on ExxonMobil Corporate Noise General Practices, noise levels in all indoor or outdoor work areas will have to meet personal exposure levels that are more stringent than the Occupational Safety and Health Administration (OSHA) Occupational Noise Exposure Standard (29 CFR 1910.95). In areas where these exposure levels cannot be met, a number of engineering mitigation measures will be implemented. Facility noise mitigation measures incorporated in design will include installation of acoustic panels on the inside of exterior walls of select modules. Turbine exhaust silencers will be installed to effectively achieve calculated noise mitigation. Noise enclosures will be installed around turbines, thus reducing emitted noise levels.

As a result of these design mitigation measures, the SoundPLAN model indicated that sound levels at the Central Pad's boundaries were reduced to levels between 48 and 61 A-weighted scale decibels (dBA). For comparison, an idling off-highway vehicle is approximately 60 dBA from 20 feet away, and an off-highway vehicle at high engine revolution is about 90 dBA from 20 feet away (reference: *Fish Creek Off-Highway Vehicle Park Noise Study*, 2008, Prepared for the City and Borough of Juneau).

4.18 WASTE MANAGEMENT

Proposed Project development concerns associated with waste management are impacts to wildlife and wildlife habitat from wastes that are not properly contained and handled.

4.18.1 Summary

The primary mitigation measure for reducing adverse effects from waste handling is to develop and implement comprehensive waste management plans. The Waste Management Plan used for drilling PTU-15 and PTU-16 will be modified to address the type and quantity of wastes generated during construction, drilling, and operations, as needed.

4.18.2 Background Context

Proper storage and disposal of wastes is important in protecting the environment and wildlife. If not properly handled, fish and wildlife could be exposed and potentially affected. Improperly handled wastes can also cause environmental contamination.

4.18.3 Mitigation Measures

ExxonMobil is developing and implementing a comprehensive Project Waste Management Plan prior to the generation of wastes. Integral parts of the overall Waste Management Plan are effective mitigation measures, including: avoiding waste generation (where possible), waste minimization, product substitution, beneficial reuse, recycling, and proper disposal. The Waste Management Plan will address storage, transportation, and disposal of wastes generated during construction, drilling, and operations. Wastes will be handled in accordance with the North Slope industry standard, *Alaska Waste Disposal and Reuse Guide* (Red Book), in full compliance with federal, state, and NSB regulatory requirements. Elements of the Waste Management Plan will include:

- Recycling/reusing drilling mud to the extent practicable, and spent drilling muds and cuttings will be injected into an onsite or offsite disposal well. Tanks or lined pits will be used for temporary storage of drilling muds and cuttings.
- Segregating and storing wastes using appropriate containers, including dumpsters, hoppers, bins, etc. for food waste, burnable (non-food) waste, construction debris, oily waste, and scrap metal.
- Segregating and securing hazardous waste in a hazardous waste Central Accumulation Area. Satellite Accumulation Areas will be provided, as needed.
- Incinerating camp waste (including food waste).
- Identifying recyclable materials and associated proper handling and storage methods. Recyclable Accumulation Areas will be provided, as needed.
- Providing storage hoppers and bins for contaminated snow.
- Providing domestic wastewater treatment system(s).
- Providing Class I non-hazardous disposal well for approved liquid waste disposal.

Most waste fluids from drilling, production, operations and maintenance, and domestic sources will be injected into a Class I disposal well (already permitted), when available. Alternate means of disposal may be needed, and will be subject to appropriate permit conditions (e.g., APDES and/or NPDES for surface discharge) and handling methods. Some wastes and recyclable materials will be transported to other Alaska North Slope locations, or transferred to other facilities in Alaska or the Lower-48 states for treatment, disposal, or recycling. All hazardous waste must be sent to authorized off-site disposal facilities. These wastes will be consolidated and stored onsite in designated accumulation areas prior to transport. Hauling waste offsite is seasonally limited. During the open-water season, waste hauling from the Project area is available by barges/vessels. During the winter, waste hauling may occur via an ice road or tundra travel. Waste may also be removed by air.

Of particular concern is the handling of food wastes and food-related garbage to prevent attracting wildlife to Project facilities. Food wastes and garbage that could attract wildlife will be

incinerated on a daily basis. Such wastes will temporarily be stored in enclosed bear-proof containers until incinerated.

Likewise, sewage and wastewater odors could attract wildlife. The Central Pad camp will have a wastewater treatment plant. Sewage sludge will be incinerated on-site regularly, or stored in enclosed tanks prior to shipment to the NSB treatment plant in Deadhorse.

4.19 SPILL PREVENTION AND RESPONSE

Oil and other hazardous substance spills may occur during construction, drilling, and operations. While a large spill is very unlikely, even small spills can have environmental or subsistence consequences if not properly responded to.

4.19.1 Summary

To protect the project workers and the environment, and to comply with the requirements of ExxonMobil's OIMS and **Protect Tomorrow. Today.**, the Project has employed state-of-the-art oil spill prevention measures that go beyond regulatory requirements and many industry standards. A partial list of the key mitigation measures related to spill prevention and response is provided below, with additional measures described in the text:

- Pipelines and facilities will use state-of-the-art techniques to prevent, monitor, and mitigate corrosion and otherwise prevent spills, including:
  - Two independent leak detection systems for the PTEP.
  - Routine visual inspections for PTEP and gathering lines.
  - Internal and external piping corrosion monitoring program.
  - Secondary containment for stored liquids.
- PTEP and gathering lines wall thickness will be sufficient to resist incidental bullet strikes from coastal hunters.
- Drilling will be conducted in accordance with comprehensive plans and follow strict procedures. Drilling related mitigation including the following are described in more detail below and include:
  - Comprehensive well planning process.
  - Drilling rig designed/upgraded specifically to meet Point Thomson drilling requirements.
  - Four-ram type blowout preventers vs. three for normal North Slope operations.
  - Comprehensive Well Control Blowout Contingency Plan.
  - Adherence to seasonal drilling restrictions which limit drilling into hydrocarbon zones to winter conditions.
- Fuel transfer procedures.

While there is a strong focus on prevention, the Project also has a strong response capability to address any spills that may occur, small or large. Key mitigation measures related to spill response include:

- Developing and implementing comprehensive spill response plans – ODPCP, Spill Prevention Control and Countermeasure (SPCC) Plans, and Facility Response Plans (FRPs).
- Training and drills for personnel.
- Access to about 600 trained responders within 24 to 48 hours.
- On-site Alaska Clean Seas (ACS) personnel.
- On-site spill response equipment.
- Oil Spill Contingency Mitigation Agreement.

4.19.2 Background Context

Oil and hazardous substances spills can cause safety and health risks to workers, environmental damage, and potential impacts to subsistence and local communities. Accordingly, spill prevention and response are extremely important to the successful implementation of the Project. A significant effort goes into spill prevention. To be ready for any spills that may occur, comparable efforts are put into developing contingency plans used to respond to spills. Personnel are trained to ensure the prevention and response plans will be effectively implemented.

4.19.3 Mitigation Measures

Overall Project drilling, producing, and pipeline operations are focused on safely containing hydrocarbons inside the wellbores, processing facilities, and pipelines. Numerous spill prevention and response measures have been and will be implemented at Point Thomson through the design, construction, drilling, and operations phases. Each of these phases will have one or more separate management processes addressing spill prevention and response. The following discussions are intended to provide a broad understanding of these measures.

This section is divided into mitigation measures that apply to all phases of the Project, including drilling, as well as those specialized measures that only apply to drilling.

4.19.3.1 Project-Wide Prevention and Response Measures

Mitigation measures that apply to all phases of the Project are summarized below.

4.19.3.1.1 Spill Prevention and Response Plans

ExxonMobil has developed comprehensive spill prevention and response plans including an ODPCP, SPCC Plans, and FRPs. These plans provide the overall framework for prevention and response measures. The plans will be maintained and updated to reflect the evolving nature of the Project operations. Key requirements under the plans include:

- All facilities and pipelines will be designed to ensure safe containment of all hydrocarbons.
- North Slope-based Project workers will attend the Project-specific “Arctic Pass” training program and the NSTC “Unescorted Course,” covering environmental excellence (among other topics) to ensure best practices of spill prevention. Contractors may also attend additional training provided by their respective employers.

- Special prevention programs will be developed where a need is identified. Examples include:
  - A special Barging Spill Management Program. An element of this program is that every team member is considered to be a “spill champion.” As such, each individual is expected to be a steward of the environment, looking out for leaks on equipment, or for any other environmental hazards present during work activities.
  - A targeted Ice Road Spill Management Program. This includes a “Drips and Drops” Program to identify the causes/sources of small drips and drops, and learn from these observations to both reduce their number and avoid potentially larger spills. This program also includes strict vehicle maintenance and inspection requirements, and limiting the use of older vehicles. Construction equipment is inspected to help identify/prevent leaks or other mechanical defects of vehicles prior to leaving Deadhorse or Point Thomson.

To implement effective response plans, it will be necessary to have sufficient numbers of properly trained personnel. This is an ExxonMobil priority. Personnel are trained in the Incident Command System (ICS), Hazardous Waste Operations and Emergency Response (Hazwoper), and other specialties as needed by position. The response drills and exercises to maintain readiness will include federal, state, and NSB personnel. There are currently estimated to be about 600 trained responders available within 24 to 48 hours, as summarized below (these numbers will vary over time):

- Point Thomson Spill Response Team (SRT); approximately 10 people who are part of the onsite workforce.
- An Anchorage-based Incident Management Team (IMT); approximately 60 people who are prepared to respond to any spill event.
- ExxonMobil’s North American Regional Response Team is comprised of about 130 personnel. Approximately 45 personnel can be mobilized to Alaska in less than 24 hours in the event of a major spill response effort, as needed.
- ExxonMobil retains ACS as its Oil Spill Removal Organization (OSRO). ACS owns response equipment totaling over $50 million and has about 80 employees, all of whom are available to assist in an oil spill response at Point Thomson.
- The North Slope Operators North Slope Spill Response Team (NSSRT) mutual aid program maintains over 115 volunteers on the North Slope who are trained and qualified to assist in spill response.
- Through ACS, ExxonMobil has access to over 250 qualified spill responders through contracts with the Auxiliary Contract Response Team.
- ACS Village Response Teams currently have over 15 qualified spill responders, and are continually recruiting new members.

4.19.3.1.2 Design, Construction, and Operations Measures

Containment of hydrocarbons and prevention of spills is a major focus during Project design efforts. Similarly, construction and operations phases of the Project will employ numerous measures to prevent spills and to rapidly respond to any that may occur. Some of the general measures include:

- The well pad locations were chosen to allow development of offshore portions of the reservoir from onshore pads, thereby avoiding placement of drilling structures in marine waters. Small spills that might otherwise escape the pads and enter marine waters will be contained on the onshore pads or adjacent land.
- Formal Hazard and Operability for Process Hazard Analyses (HAZOPs), risk assessment, facility site reviews, design readiness review, independent project review, and constructability reviews will be used to identify potential spill risks and associated prevention or response measures.
- Storage tanks for oil and hazardous substances will be located within impermeable secondary containment areas. These storage tanks will not be stored within 100 feet of waterbodies, unless otherwise approved by the appropriate regulatory agencies.
- Spill response equipment and materials will be readily available at designated locations throughout the facility.
- Hazardous waste storage will also be located within impermeable secondary containment areas.
- Fuel transfers will follow BMPs, including using secondary containment devices. Refueling and transfer sites will be located away from the shoreline and river crossings and outside active floodplains.

The Point Thomson pipelines (PTEP and in-field gathering lines) will be based on state-of-the-art Arctic designs, specifically tailored for the Project. Prevention and leak detection measures common to both pipeline systems will include:

- Pigging facilities to allow running in-line inspection, maintenance, and cleaning tools:
  - The in-line inspection tools (smart pigs) will be used to monitor both internal and external corrosion.
  - The maintenance and cleaning pigs will remove sediment from the lines, thereby reducing the potential for corrosion.
- Internal corrosion will also be monitored through the use of corrosion coupons and Electrical Resistance (ER) probes that provide a measure of corrosion rate and activity. The ability to inject a corrosion inhibitor will be provided.
- A wall thickness to withstand damage from incidental bullet strikes from coastal subsistence hunters. Additional wall thickness will be added, where necessary, to meet this criterion.
- External corrosion prevention through use of shop-installed polyurethane foam insulation covered with a roll-formed, interlocked, and galvanized metal jacket. This insulation-jacket system has a proven North Slope track record of preventing moisture ingress, which can lead to external corrosion. The pipeline will be shop fusion bonded epoxy (FBE) coated and field joints will be coated with field applied coating, insulation, sealing, and jacketing to coincide with best available North Slope practices.
- Pipeline hydrostatic testing to verify pipeline integrity in accordance with 49 CFR 195 (PTEP) and American Society of Mechanical Engineers B31.8 (gathering lines).
- Visual inspections of the pipelines will typically be conducted weekly during operations via aerial surveillance, unless precluded by safety or weather conditions.

The prevention measures unique to the PTEP include:

- Isolation valves at pipeline inlet at the Central Pad and at pipeline outlet at Badami to allow rapid shut-in in the event of a leak or rupture.
- Use of vertical loops at the East Badami Creek to limit the amount of liquid hydrocarbon that could be spilled in the event of a pipeline leak or rupture. The vertical loops eliminate the need for valve pads on either side of the creeks, thus minimizing gravel placement and possible leak source (valve).
- An additional wall-thickness for corrosion allowance.
- Internal corrosion of the PTEP will be controlled by dehydration of the liquid hydrocarbon product and injection of corrosion inhibitors, when needed.
- The use of two half-shell, pre-form weld pack field joints with small channel for water draining to minimize corrosion under insulation.
- Two independent leak detection systems will be installed. The primary system will meet ADEC's requirement to detect a leak as small as 1 percent of the daily flow rate. This system will use meters on the inlet and outlet of the PTEP, with a state-of-the-art computational system that will perform real-time monitoring for pipeline leaks and will be continually updated via a supervisory control and data acquisition (SCADA) system. An ExxonMobil proprietary leak detection system using different technology will provide another level of protection.

The prevention measures unique to the infield gathering lines will include:

- Use of corrosion resistant alloy (CRA) materials to reduce the potential for internal corrosion.
- Designed to contain full shut-in pressure of the wells. This avoids the need for pressure relief devices and vent systems to prevent over pressure and associated release to the environment.

4.19.3.2 Drilling-Specific Prevention and Response Measures

Drilling operations at Point Thomson are unique to the North Slope and many special spill prevention and response measures are used. While some drilling mitigation measures are regulatory conditions (e.g., limiting drilling into hydrocarbon zones during certain seasons of the year or Alaska Oil and Gas Conservation Commission [AOGCC] drilling-related regulations), most of the following are based on ExxonMobil's drilling experience and practices. Measures implemented during drilling have included, and will continue to include as appropriate, those listed below.

4.19.3.2.1 Training

Having properly-trained personnel is critical to safe and successful drilling operations. It is necessary to provide training to ensure drilling personnel understand the procedures to safely maintain control of the wells. Key training includes certified well control training for: drilling supervisors, operations superintendents, drilling engineers, contractor rig drillers, tool pushers, assistant drillers, derrickmen, and other appropriate personnel. The curriculum consists of training in blowout prevention technology, well control, and Training to Reduce Unexpected Events (TRUE).

TRUE involves a multifunctional team made up of the rig contractor, service company, and operator personnel prior to commencing operations, and focuses on increasing knowledge and awareness to prevent and deal with potential hazards at Point Thomson. The training is based specifically on Point Thomson wells, and its goal is to provide site-specific solutions to potential problems before they occur. Potential hazards are defined by the team, including well control and lost returns. Action plans are developed to identify roles and responsibilities, warning signs, how to react to an event, and lines of communication. Special emphasis is placed on abnormal pressure detection and well control. The training establishes a team concept and a team approach to identifying and solving problems.

4.19.3.2.2 Well Planning

The comprehensive well planning process for the Point Thomson PTU-15 and PTU-16 wells was the first step in preventing spills or releases and ensuring the safe drilling of the wells. This planning process will be applied to the drilling of future Point Thomson wells.

During well planning, ExxonMobil uses an Integrated Pore Pressure Prediction (IP3) Team consisting of reservoir engineers, geologists, drilling engineers, and computer modelers. The IP3 Team analyzes seismic data, data from exploration wells, and geologic models to predict pore pressure and fracture gradients, as well as to develop a detailed understanding of the reservoir. The use of advanced technology enables accurate prediction of formation behavior as wells are drilled, and allows the engineer to plan a well that minimizes the risk of a well control incident. In addition, bottom-hole pressure data from other wells in the area and seismic data are reviewed to ascertain the expected bottom-hole pressure at the proposed well location.

The bottom-hole pressure predictions are used to design a drilling mud program with sufficient hydrostatic head (determined by the mud density or “weight” and height of the mud column) to overbalance the formation pressures from surface to total well depth. Other factors influencing the mud weight design are shale conditions, fractures, lost circulation zones, under-pressured formations, and stuck-pipe prevention. The well casing program is designed to allow for containment and circulation of formation fluid influx out of the wellbore without fracturing open formations.

4.19.3.2.3 Drilling Rig and Well Control/Blowout Prevention Equipment

More and higher pressure-rated blowout prevention equipment (BOPE) than other North Slope drilling will be used for Point Thomson. During drilling operations below the surface-hole, the Point Thomson BOPE will consist of:

- A minimum of four, 13 5/8-inch, 10,000 pounds per square inch (psi) working pressure, ram-type preventers.
- One 13 5/8-inch annular preventer (rated to 10,000 psi).
- Choke and kill lines that provide circulating paths from/to the choke manifold.
- A two-choke manifold that allows for safe circulation of well influx out of the wellbore.
- A hydraulic control system with accumulator backup closing capability.

While most North Slope drilling operations use four blowout preventers (BOPs – three ram-type and one annular type), a fifth preventer was incorporated into the BOP stack arrangement to manage the risk at Point Thomson. A BOP stack with four sets of rams and one annular

preventer will be used to drill below surface casing, providing one more preventer than required by AOGCC regulations. This arrangement allows two preventers to close on the casing and liners and, in the case of liners, permits two ram-type and one annular preventer to be used on the drill-pipe running-string without having to stop and change out rams. The extra ram preventer will also provide added redundancy.

Prior to acceptance of the drilling rig, comprehensive inspection and testing will be performed on the BOPE, including:

- Test BOPE to the full rated working pressure (10,000 psi).
- Test choke manifold equipment to the full rated working pressure.
- Test the BOP accumulator unit to confirm that closing times meet American Petroleum Institute standards and meet or exceed AOGCC requirements.
- Verify pre-charge pressure and total volume of the accumulator bottles.
- Install new ring gaskets and seals between each BOP component.
- Test pressure integrity of the high-pressure mud system.
- Inspect drill string and bottom-hole assembly (BHA) components to the most stringent "T.H. Hill DS-1 Category 5 level."[7] While operating, the BOPE will be tested according to AOGCC and ExxonMobil requirements, which is typically every 7 or 14 days. AOGCC field inspectors may witness these pressure tests.

4.19.3.2.4 Well Control While Drilling Below the Surface Hole

The following discussions present detailed information on Project measures for well control while drilling below the surface hole.

Well Control Monitoring and Procedures. Each well will be drilled according to a detailed well plan. While drilling, the well will constantly be monitored for pressure control. The mud weight (the primary well control mechanism) will be monitored and adjusted to meet actual wellbore requirements. A range of mud weights will be used as the well is drilled to provide the proper well control for the formation conditions encountered. Automatic and manual monitoring equipment will be installed to detect abnormal variation in the mud system volumes and drilling parameters.

If an influx of formation fluid (kick) occurs, secondary well control methods will be employed. Constant monitoring of the total fluid circulating volume and other drilling parameters will ensure that a kick is quickly detected. The well annulus will be shut-in using the BOPE. The drill pipe will be shut-in by a downhole check valve near the bit and a surface-mounted valve. This will contain the influx and associated build-up of surface pressure. It will also prevent further influx of formation fluid into the wellbore. After the well is stabilized, a well kill procedure will be developed and implemented to circulate kill-weight mud and safely remove formation fluids from the hole. Mud-gas separators and degassers will be used to remove gas from the mud as it is circulated out of the hole. After this procedure is completed, the kill effectiveness will be

[7] "T.H. Hill DS-1 Category 5 level" refers to an inspection and qualification document written by T.H. Hill Associates, Inc., that is considered industry standard for drill string and BHA inspections, as well as quality control of the drill string equipment.

confirmed and the well will be opened up and the fluid levels monitored. Drilling operations will not resume until conditions are normal.

BOP drills will be performed on a frequent basis to ensure the drilling crews can quickly and properly shut-in the well. Certified training of Point Thomson personnel will include hands-on simulator practice at recognizing kicks, well shut-in, and circulating the kicks out of the wellbore.

Bottom-Hole Pressure Measurements. ExxonMobil will measure bottom-hole pressure while drilling, with computer-assisted analysis of drilling fluids circulation. ExxonMobil will use state-of-the-art technology to enhance drilling performance and mitigate risk. Several of the technologies are known as logging while drilling (LWD) and pressure while drilling (PWD). The LWD system enhances early detection of over-pressured intervals or possible lost circulation zones. The PWD system directly monitors bottom-hole pressures to maintain sufficient overbalance without compromising the formation integrity. Early detection of overpressure and maintaining sufficient overbalance while drilling will minimize the chance of incurring a well control event.

Overbalanced Drilling Confirmation Technique. The “10/10/10 Test” developed by ExxonMobil is an analytical technique to help evaluate whether an overbalanced situation exists in the wellbore. Testing using the 10/10/10 Test can provide accurate and early diagnostics of the formation pressure before the potential kick interval is reached. The 10/10/10 Test involves circulating the well for 10 minutes to establish background gas, discontinuing mud circulation for 10 minutes to reduce equivalent circulating density, and circulating the wellbore for an additional 10 minutes. Mud is then circulated from the bottom of the well, without further drilling, to the surface. Gas concentrations are measured, and an evaluation is done to determine whether the overbalance is sufficient.

Computer-aided Management of Inspection, Maintenance, and Repair. ExxonMobil will use a computerized preventive maintenance program to help manage inspection, maintenance, and repair of the drilling rig and associated equipment. The drilling contractor’s preventive maintenance program will be reviewed, a gap analysis will be performed, and an agreed-upon computer-aided system will be followed. The contractor will have the responsibility to maintain the program, while the operator closely monitors the inspection, maintenance, and repair program.

Well Control Blowout Contingency Plan. While the potential for a blowout at Point Thomson is extremely low, ExxonMobil has developed a Well Control Blowout Contingency Plan (BCP) to address controlling a potential blowout in the shortest possible time. The BCP relies upon well capping as the primary means of controlling a blowout. Well capping is proven and will normally control a blowout in far less time than a relief well. The BCP address critical logistical elements of bringing the well capping equipment to the location.

A key element of the BCP is ignition of a Thomson Sand gas condensate blowout. This is an effective method of “source control.” Air quality modeling has demonstrated that such a blowout would burn cleanly and would not violate national ambient air quality standards. ADEC has granted pre-approval for wellhead ignition and ExxonMobil will be prepared to implement well ignition within 2 hours of a blowout occurring, if that is the chosen response measure.

April 1, 2011
ER-2011-OUT-094

Mr. Johnny Aiken, Jr.
Executive Director
Alaska Eskimo Whaling Commission
Post Office Box 570
Barrow, Alaska 99723

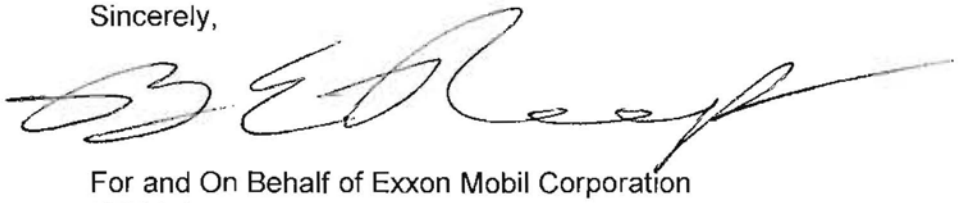
Re: 2011 Conflict Avoidance Agreement (CAA)

Dear Mr. Aiken:

We are pleased to transmit ExxonMobil's executed signature page to the 2011 Conflict Avoidance Agreement (CAA). This is the fourth consecutive year in which ExxonMobil has been a participant in the CAA as a result of development of the Point Thomson Project.

ExxonMobil would like to acknowledge the ongoing efforts of the AEWC, its members, the Whaling Captains' Associations, and your counsel and staff to further improve the 2011 CAA. The CAA process provides a good forum in which the whalers and industry can meet and discuss issues of interest and mutual concern. ExxonMobil also appreciates the willingness of the Commission and its members to address clarifications to the CAA arising from this process. We are committed to working with the AEWC and its members on a transparent and continuing basis to ensure that concerns of all participants in the CAA can be addressed in a mutually agreeable fashion.

This year ExxonMobil does not currently anticipate coastal barging operations in 2011 for the Point Thomson Project. However, a determination on the need for possible barging will be made at the conclusion of the ice road season, approximately the end of April. If barging occurs, it will likely be on a limited basis. ExxonMobil will also determine at that time whether, as a result of possible barging, it will participate in supporting Beaufort Sea Communications Centers at Deadhorse and Kaktovik. Notwithstanding the possibility that barging operations may not be necessary this year, ExxonMobil continues to support the CAA process.



ExxonMobil appreciates the improved clarity in the CAA about the provisions concerning coastal transit and barging. We also appreciate the clarification that sound signature tests for tugs, formerly included in Section 302(f), are not required. Should ExxonMobil's operations change in the future such that additional provisions of the CAA would be applicable to our operations, we would seek to engage the AEWC in an open and constructive dialogue to mutually address any concerns presented by provisions which are not applicable to our current operations.

ExxonMobil will also continue to consult with the Whaling Captains' Associations of Kaktovik and Nuiqsut as appropriate to ensure that any barging operations which may occur have minimal possible impact on subsistence whaling. We also note that we would again plan to operate our barging operations within the barrier islands and closer to shore than is otherwise called for by the CAA, which should improve our capability to provide search and rescue support in the area between Prudhoe Bay and Point Thomson.

Thank you again for your efforts to complete the 2011 CAA. We look forward to working with the AEWC and its members in the future to continue to improve the CAA. Also enclosed is a check for $75,000 to help defray the AEWC administrative costs associated with revision and implementation of the CAA.

If you have questions, please contact me at 907-564-3617 or email at brien.e.reep@exxonmobil.com or Rachel Cox at 907-564-3737 or email at rachel.r.cox@exxonmobil.com.

Sincerely,

For and On Behalf of Exxon Mobil Corporation
BER:kdc:eaa

TITLE I – GENERAL PROVISIONS

SECTION 101. APPLICATION.

Title I applies to all Participants.

Title II applies to all Participants, except as provided in Titles III or VI.

Title III applies to those Participants who operate barge or transit vessels in the Beaufort Sea or Chukchi Sea.

Titles IV and V apply only to those Participants who engage in oil and gas operations.

TItle VI applies to those Participants who engage exclusively in geophysical activities that are conducted at least 40 miles or more from the Alaska coast in the Beaufort Sea or Chukchi Sea and begin on or after October 1, 2011.

Provisions that apply to a specific activity or are designated as specific to either the Beaufort Sea or Chukchi Sea apply only to Participants that engage in that activity or operate in that area, and provisions applicable to activities a Participant does not engage in or areas in which a Participant does not operate do not apply to that Participant.

SECTION 102. PURPOSE.

The purpose of this Agreement is to provide:

(1) Equipment and procedures for communications between Subsistence Participants and Industry Participants;

(2) Avoidance guidelines and other mitigation measures to be followed by the Industry Participants working in or transiting the vicinity of active subsistence hunters, in areas where subsistence hunters anticipate hunting, or in areas that are in sufficient proximity to areas expected to be used for subsistence hunting that the planned activities could potentially adversely affect the subsistence bowhead whale hunt through effects on bowhead whales;

(3) Measures to be taken in the event of an emergency occurring during the term of this Agreement; and

(4) Dispute resolution procedures.

SECTION 103. DEFINITIONS.

(a) Defined Terms.

For the purposes of this Agreement:

(1) The term “Agreement” means this 2011 Open Water Season Programmatic Conflict Avoidance Agreement and any attachments to such agreement.

(2) The term “at-sea oil and gas operations” does not include gravel islands or fixed platform developments located near shore (for example Northstar or Oooguruk) or Near Shore Operations Support Vessels.

(3) The term “barge” means a non-powered vessel that is pushed or towed, and the accompanying pushing or towing vessel, which is used solely to transport materials through the Beaufort Sea or Chukchi Sea. Such term does not include any vessel used to provide supplies or support to at-sea oil and gas operations or Near Shore Operations Support Vessels.

(4) The term “Com-Center” means a communications systems coordination center established under Section 203.

(5) The term “geophysical activity” means any activity the purpose of which is to gather data for imaging the marine subsurface environment, including but not limited to use of air guns, sonar, and other geophysical equipment used for seismic exploration or shallow hazard identification.

(6) The term “geophysical equipment” means equipment, such as air gun arrays over 300 cubic inches or sparker arrays over 20,000 kJ, employed on a vessel or a towed array, that generates sound waves for the purpose of imaging the subsurface marine environment for exploration and development purposes. The term does not include vessel engines, generators, or sources such as fathometers, fish finders, side-scan sonar, or other sources intended for engineering and /or transportation purposes.

(7) The term “Industry Participants” means all parties to this Agreement who are not Subsistence Participants.

(8) The term “Marine Mammal Observer / Inupiat Communicator” or “MMO/IC” means an observer hired by an Industry Participant for the purpose of spotting and identifying marine mammals in the area of that Industry Participant’s operations during the Open Water Season. The MMO/IC also serves as the on-board Inupiat communicator who can communicate directly with whaling crews.

(9) The term “Near Shore Operations Support Vessels” means vessels (including aircraft) used to support related activities (such as supply, re-supply, crew movement, and facility maintenance) for near shore oil and gas operations by an Industry Participant.

(10) The terms “NSB” and “NSB DWM” mean the North Slope Borough and the North Slope Borough Department of Wildlife Management, respectively.

(11) The term “oil and gas operations” means all oil and gas exploration, development, or production activities (including, but not limited to, geophysical activity, exploratory drilling, development activities (such as dredging or construction), production drilling, or production, and related activities (such as supply, re-supply, crew movements, and facility maintenance) by or for any Industry Participant, including aircraft and vessels of whatever kind used in support of such activities, occurring in the Beaufort Sea or Chukchi Sea, whether occurring near shore or offshore, but does not include barge traffic, transit vessel traffic, cable laying vessel traffic, or research vessel traffic (i.e. traffic by a vessel which is only conducting research and is not conducting any geophysical activities) by or for any Participant.

(12) The term “Open Water Season” means the period of the year when ice conditions permit navigation or oil and gas operations to occur in the Beaufort Sea or Chukchi Sea, as appropriate.

(13) The term “Participants” means all parties identified in this Agreement by name and whose representative(s) has signed the Agreement, and all contractors of such parties. When used alone the term includes both Industry Participants and Subsistence Participants.

(14) The term “Primary Sound Source Vessel” means a vessel owned or operated by or for an Industry Participant that (A) employs air gun arrays greater than 300 cubic inches or sparkers greater that 20,000 kJ, for imaging the subsurface environment, (B) is used to monitor any safety zone around a vessel described in subsection (A), (C) is engaged in ice-breaking, or (D) is the lead vessel in a group of barge or transit vessels.

(15) The term “sonar” means equipment, employed as hull mounted or towed array, intended for the active location of surface or underwater vessels. The term does not include vessel engines, generators, or sources such as fathometers, fish finders, side-scan sonar, or other sources intended for engineering, cable laying or routing, and/or transportation purposes.

(16) The term “Subsistence Participants” means the Alaska Eskimo Whaling Commission (AEWC) and its members, including the whaling captains’ associations identified on the cover of this Agreement, as well as any individual members of those associations.

(17) The term “transit vessel” means a powered vessel that is used solely to transport materials through the Beaufort Sea or Chukchi Sea. Such term does not include a vessel used to provide supplies or other support to at-sea oil and gas operations or Near Shore Operations Support Vessels.

(b) Geographically Limited Terms.

For the purposes of this Agreement:

(1) The term “Beaufort Sea” means all waters off the northern coast of Alaska from Point Barrow to the Canadian border.

(2) The term “Chukchi Sea” means all waters off the western and northern coasts of Alaska from Cape Prince of Wales to Point Barrow.

SECTION 104. TERM, SCOPE, AND LIMITATIONS.

(a) Term.

The term of this Agreement shall commence with the signing of this document by the Participants and shall terminate upon completion of the Nuiqsut, Kaktovik, Barrow, Wainwright, Pt Lay, and Pt. Hope Fall Bowhead Hunts or the Beaufort Sea Post Season Meeting required under Section 108(a) and Chukchi Sea Post-Season Meetings in Barrow, Wainwright, Pt. Lay, and Pt. Hope required under Section 108(b), whichever is later.

(b) Scope.

The Participants agree that, unless otherwise specified:

(1) The mitigation measures identified in this Agreement, which are intended to mitigate interference by oil and gas operations and barge and transit vessel traffic with the Alaskan Eskimo subsistence bowhead whale hunt, are designed to apply to all activities of each Participant during the 2011 Open Water Season, whether referenced specifically or by category, and to all vessels and locations covered by this Agreement, whether referenced specifically or by category.

(2) This Agreement is intended to apply to all oil and gas operations and barge and transit vessel traffic during the 2011 Open Water Season in the Beaufort Sea or Chukchi Sea.

(3) Vessels and locations covered by this Agreement include those identified in the Agreement, as well as any other vessels or locations that are employed by or for the Industry Participants in the Beaufort Sea or Chukchi Sea during the 2011 Open Water Season.

(c) Limitations of Obligations.

The following limitations apply to this Agreement.

(1) No cooperation among the Participants, other than that required by this Agreement, is intended or otherwise implied by their adherence to this Agreement. In no event shall the signatures of any representative of the Alaska Eskimo Whaling Commission (AEWC), or of the Barrow, Nuiqsut, Kaktovik, Wainwright, Pt. Hope, or Pt. Lay Whaling Captains' Associations, or of any other Whaling Captains' Association be taken as an endorsement of any Arctic operations or Beaufort Sea or Chukchi Sea OCS operations by any oil and/or gas operator or contractor.

(2) Adherence to the procedures and guidelines set forth in this Agreement does not in any way indicate that any Inupiat or Siberian Yupik whalers or the AEWC agree that industrial activities are not interfering with the bowhead whale migration or the bowhead whale subsistence hunt. Such adherence does not represent an admission on the part of the Industry Participants or their contractors that the activities covered by this Agreement will interfere with the bowhead whale migration or the bowhead whale subsistence hunt.

(3) No member of the oil and gas industry or any contractor has the authority to impose restrictions on the subsistence hunting of bowhead whales or associated activities of the AEWC, residents of the Villages of Nuiqsut, Kaktovik, Barrow, Wainwright, Pt. Lay, or Pt. Hope, or residents of any other village represented by the AEWC.

(4) In the event additional parties engage in oil and gas operations in the Beaufort Sea or Chukchi Sea during the summer or fall of 2011 the Participants shall exercise their good-faith efforts to encourage those parties to enter into this Agreement. Should additional parties enter into this Agreement at a date subsequent to the date of the signing of this document and before the termination of the 2011 bowhead whale subsistence hunting season, the AEWC will provide to all Participants a supplement to this document with the added signatures.

(5) No Participant is responsible for enlisting additional parties to adhere to the terms and conditions of the Agreement. Similarly, **THE AEWC IS NOT RESPONSIBLE FOR, OR A PARTY TO, ANY AGREEMENT AMONG THE INDUSTRY PARTICIPANTS** concerning the apportionment of expenses necessary for the implementation of this Agreement.

(6) In adhering to this Agreement, none of the Participants waives any rights existing at law. All Participants agree that the provisions of this document do not establish any precedent as between them or with any regulatory or permitting authority.

(7) **PARTICIPANTS' OBLIGATIONS SHALL BE SEPARABLE**: All Participants to this Agreement understand that each Participant represents a separate entity. The failure of any Participant to adhere to this Agreement or to abide by the terms and conditions of this Agreement shall not affect the obligation of other Participants to adhere to this Agreement and to proceed accordingly with all activities covered by this Agreement. Nor shall any Participant's adherence to this Agreement affect that Participant's duties, liabilities, or other obligations with respect to any other Participant beyond those stated in this Agreement. If an Industry Participant does not receive permit approvals from regulatory agencies to conduct its proposed activities, then that company may withdraw from this Agreement.

SECTION 105. REGULATORY COMPLIANCE.

(a) United States Coast Guard Requirements.

The Participants shall comply with all applicable United States Coast Guard requirements for safety, navigation, and notice.

(b) Environmental Regulations and Statutes.

The Participants shall comply with all applicable environmental regulations and statutes.

(c) Other Regulatory Requirements.

The Participants shall comply with all applicable federal, state, and local government requirements.

SECTION 106. DISPUTE RESOLUTION.

Subject to the terms of Section 104(c)(7) of this Agreement, all disputes arising between any Industry Participants and any Subsistence Participants shall be addressed as follows:

(1) The dispute shall first be addressed between the affected Participant(s) in consultation with the affected village Whaling Captains' Association and the Industry Participant(s)' Local Representative.

(2) If the dispute cannot be resolved to the satisfaction of all affected Participants, then the dispute shall be addressed with the affected Participants in consultation with the AEWC.

(3) If the dispute cannot be satisfactorily resolved in accordance with paragraphs (1) and (2) above, then the dispute shall be addressed with the AEWC and the affected Participants in consultation with representatives of NOAA Fisheries.

(4) All Participants shall seek to resolve any disputes in a timely manner, and shall work to ensure that requests for information or decisions are responded to promptly.

SECTON 107. EMERGENCY AND OTHER NECESSARY ASSISTANCE.

(a) Emergency Communications.

ALL VESSELS SHOULD NOTIFY THE APPROPRIATE COM-CENTER IMMEDIATELY IN THE EVENT OF AN EMERGENCY. The appropriate Com-Center operator will notify the nearest vessels and appropriate search and rescue authorities of the problem and advise them regarding necessary assistance. (See attached listing of local search and rescue organizations in Attachment I.)

(b) Emergency Assistance for Subsistence Whale Hunters.

Section 403 of Public Law 107-372 (16 U.S.C. 916c note) provides that "Notwithstanding any provision of law, the use of a vessel to tow a whale, taken in a traditional subsistence whale hunt permitted by Federal law and conducted in waters off the coast of Alaska is authorized, if such towing is performed upon a request for emergency assistance made by a subsistence whale hunting organization formally recognized by an agency of the United States government, or made by a member of such an organization, to prevent the loss of a whale." Industry Participants will advise their vessel captains that, under the circumstances described above, assistance to tow a whale is permitted under law when requested by a Subsistence Participant. Under the circumstances described above, Industry Participants will provide such assistance upon a request for emergency assistance from a Subsistence Participant, if conditions permit the Industry Participant's vessel to safely do so.

SECTION 108. POST-SEASON REVIEW / PRESEASON INTRODUCTION.

(a) Beaufort Sea Post-Season Joint Meeting.

Following the end of the fall 2011 bowhead whale subsistence hunt and prior to the 2012 Pre-Season Introduction Meetings, the Industry Participant that establishes the Deadhorse and Kaktovik Com Centers will offer to the AEWC Chairman to host a joint meeting with all whaling captains of the Villages of Nuiqsut, Kaktovik and Barrow, the Marine Mammal Observer / Inupiat Communicators stationed on the Industry Participants' vessels in the Beaufort Sea, and with the Chairman and Executive Director of the AEWC, at a mutually agreed upon time and place on the North Slope of Alaska, to review the results of the 2011 Beaufort Sea Open Water Season, unless it is agreed by all designated individuals or their representatives that such a meeting is not necessary.

(b) Chukchi Sea Post-Season Village Meetings.

Following the completion of the 2011 Chukchi Sea Open Water Season and prior to the 2012 Pre-Season Introduction Meetings, the Industry Participants involved, if requested by the AEWC or the Whaling Captain's Association of each village, will host a meeting in each of the following villages: Wainwright, Pt. Lay, Pt. Hope, and Barrow (or a joint meeting of the whaling captains from all of these villages if the whaling captains agree to a joint meeting) to review the results of the 2011 operations and to discuss any concerns residents of those villages might have regarding the operations. The meetings will include the Marine Mammal Observer / Inupiat Communicators stationed on the Industry Participants' vessels in the Chukchi Sea. The Chairman and Executive Director of the AEWC will be invited to attend the meeting(s).

(c) Pre-season Introduction Meetings.

(1) Immediately following each of the above meetings, and at the same location, the Industry Participants will provide a brief introduction to their planned operations for the 2012 Open Water Season. Each Industry Participant should provide hand-outs explaining their planned activities that the whaling captains can review.

(2) Subsistence Participants understand that any planned operations discussed at these Pre-Season Introduction Meetings, and the corresponding maps, will represent the Industry Participant's best estimate at that time of its planned operations for the coming year, but that these planned operations are preliminary, and are subject to change prior to the 2012 Open Water Season Meeting.

(d) Map of Planned Industry Participant Activities.

As practicable, Industry Participants shall jointly prepare and provide the AEWC with a large-scale map of the Beaufort and Chukchi Seas showing the locations and types of oil and gas and barge and transit activities planned by each Industry Participant. This map will be for use by the AEWC and Industry Participants during the 2012 CAA Meeting.

SECTON 109. INDIVIDUAL NOTIFICATION.

In the event that any Industry Participant does not become a signatory to this Agreement, the local Whaling Captains' Associations shall be notified by the AEWC, no later than June 30, 2011, so that the local Whaling Captains' Associations can prepare to talk with the non-signatories to avoid conflict during that association's fall subsistence bowhead whaling season.

TITLE II -- OPEN WATER SEASON COMMUNICATIONS

SECTION 201. MARINE MAMMAL OBSERVERS / INUPIAT COMMUNICATORS.

(a) Marine Mammal Observer / Inupiat Communicator Required.

(1) In General. Each Industry Participant agrees to employ a Marine Mammal Observer / Inupiat Communicator (MMO/IC) on board each Primary Sound Source Vessel owned or operated by such Industry Participant in the Beaufort Sea or Chukchi Sea.

(2) Special Rule for Inside Beaufort Sea Barrier Islands. Industry Participants whose seismic acquisition operations are limited to an area exclusively within the barrier islands need employ an MMO/IC on one Primary Sound Source Vessel only.

(3) Near Shore Operations Support Vessels. Industry Participants are not required to employ an MMO/IC on Near Shore Operations Support Vessels.

(4) Sealift Operations. For Industry Participants conducting sealift operations in which two tugs towing barges are accompanied within ½ mile by a third light tug at all times, a MMO/IC is required to be employed on the light tug only.

(b) Duties of Marine Mammal Observer / Inupiat Communicator.

(1) Each MMO/IC is to be employed as an observer and Inupiat communicator for the duration of the 2011 Open Water Season on the vessel on which he or she is stationed.

(2) As a member of the crew, the MMO/IC will be subject to the regular code of employee conduct on board the vessel and will be subject to discipline, termination, suspension, layoff, or firing under the same conditions as other employees of the vessel operator or appropriate contractor.

(3) Once the source vessel on which the MMO/IC is employed is in the vicinity of a whaling area and the whalers have launched their boats, the MMO/IC's primary duty will be to carry out the communications responsibilities set out in this Title.

(4) At all other times, the MMO/IC will be responsible for keeping a lookout for bowhead whales and/or other marine mammals in the vicinity of the vessel to assist the vessel captain in avoiding harm to the whales and other marine mammals.

(5) It is the MMO/IC's responsibility to call the appropriate Com-Center as set out in Sections 202 and 203.

(6) The MMO/IC will be responsible for all radio contacts between vessels owned or operated by each of the Industry Participants and whaling boats covered under Section 207 of this Agreement and shall interpret communications as needed to allow the vessel operator to take such action as may be necessary pursuant to this Agreement.

(7) The MMO/IC shall contact directly subsistence whaling boats that may be in the vicinity to ensure that conflicts are avoided to the greatest possible extent.

(8) The MMO/IC will maintain a record of his or her communications with each Com-Center and the subsistence whaling boats, as well as any marine mammal sightings by the MMO/IC.

SECTION 202. COM-CENTER GENERAL COMMUNICATIONS SCHEME.

(a) Reporting Positions for Vessels Owned or Operated by the Industry Participants.

(1) All vessels (other than vessels covered under sections 302 and 602) shall report to the appropriate Com-Center at least once every six hours commencing with a call at approximately 06:00 hours. Each call shall report the following information:

(A) Vessel name, operator of vessel, charter or owner of vessel, and the project the vessel is working on.

(B) Vessel location, speed, and direction.

(C) Plans for vessel movement between the time of the call and the time of the next call. The final call of the day shall include a statement of the vessel's general area of expected operations for the following day, if known at that time.

EXAMPLE: This is the Arctic Endeavor, operated by _____ for _____ at Chukchi Sea prospect. We are currently at ___'___ north ___'___ west, proceeding SE at ____ knots. We will proceed on this course for ___ hours and will report location and direction at that time.

(2) The appropriate Com-Center shall be notified if there is any significant change in plans, such as an unannounced start-up of operations or significant deviations from announced course, and such Com-Center shall notify all whalers of such changes. A call to the appropriate Com-Center shall be made regarding any unsafe or unanticipated ice conditions.

(3) In the event that the Industry Participant's operation includes seismic data acquisition, the operator reserves the right to restrict exact vessel location information and provide more general location information.

(b) Reporting Positions for Subsistence Whale Hunting Crews.

(1) All subsistence whaling captains shall report to the appropriate Com-Center at the time they launch their boats from shore and again when they return to shore.

(2) All subsistence whaling captains shall report to such Com-Center the initial GPS coordinates of their whaling camps.

(3) Additional communications shall be made on an as needed basis.

(4) Each call shall report the following information:

(A) The crew's location and general direction of travel.

EXAMPLE: This is _____. We are just starting out. We will be traveling north-east from _____ to scout for whales. I will call if our plans change.

(B) The presence of any vessels or aircraft owned or operated by any of the Industry Participants, or their contractors, that are not observing the specified guidelines set forth in Title V on Avoiding Conflicts.

(C) The final call of the day shall include a statement of the whaling captain's general area of expected operations for the following day, if known at the time.

(5) Any subsistence whale hunter preparing to tow a caught whale shall report to the appropriate Com-Center before starting to tow.

EXAMPLE: This is Archie Ahkiviana. I am ___'___ north, ___'___ west. I have a whale and am towing it into _____.

(6) Each time a subsistence whaling camp is moved, it shall be reported promptly to the appropriate Com-Center, including the new GPS coordinates.

(7) Subsistence whale hunters shall notify the appropriate Com-Center promptly if, due to weather or any other unforeseen event, whaling is not going to take place that day.

(8) Subsistence whaling captains shall contact the appropriate Com-Center promptly and report any unexpected movements of their vessel.

(c) Responsibilities of Participants.

(1) Monitoring VHF Channel 16.

All vessels covered by Sections 207, 301, and 401 of this Agreement shall monitor marine VHF Channel 16 at all times.

(2) Avoidance of Whale Hunting Crews and Areas

It is the responsibility of each vessel owned or operated by any of the Industry Participants and covered by Sections 301 or 401 of this Agreement to determine the positions of all of their vessels and to exercise due care in avoiding any areas where subsistence whale hunting is active.

(3) Vessel-to-Vessel Communication

After any vessel owned or operated by any of the Industry Participants and covered by Sections 301 or 401 of this Agreement has been informed of or has determined the location of subsistence whale hunting boats in its vicinity, the Marine Mammal Observer / Inupiat Communicator shall contact those boats in order to coordinate movement and take necessary avoidance precautions.

SECTION 203. THE COMMUNICATIONS SYSTEM COORDINATION CENTERS (COM-CENTERS).

(a) Chukchi Lead System Included in Com-Center Coverage.

In addition to the Beaufort Sea and Chukchi Sea, the communications scheme shall apply in the Chukchi Sea lead system, as identified and excluded from leasing in the current MMS Five-Year Leasing Program, 2007-2012.

(b) Set Up and Operation.

(1) Subject to the terms of Section 104(c) of this Agreement, the Industry Participants conducting operations in:

(A) the Beaufort Sea jointly will arrange for the funding of Com-Centers in Deadhorse and Kaktovik; and

(B) the Chukchi Sea jointly will arrange for the funding of Com-Centers in Barrow, Wainwright, Pt. Lay, and Pt. Hope.

(2) All six Com-Centers will be staffed by Inupiat operators. **GROUND TRANSPORTATION MUST BE PROVIDED FOR COM-CENTER OPERATIONS IN KAKTOVIK FOR POLAR BEAR AND BROWN BEAR SAFETY**. The Com-Centers will be operated 24 hours per day during the 2011 subsistence bowhead whale hunt. One Industry Participant in the Beaufort Sea and one Industry Participant in the Chukchi Sea, or their respective contractor, will be designated as the operator of the Com-Centers for that Sea, in consultation with the AEWC.

(3) Each Industry Participant shall contribute to the funding of the Com-Centers covering the areas in which it conducts oil and gas operations. The level of funding for the Com-Centers provided by each of the Industry Participants is intended to be in proportion to the scale of their respective activities, and shall be mutually agreed by the Industry Participants.

(4) The procedures to be followed by the Com-Center operators are set forth in subsection (d) below.

(c) Staffing.

(1) Each Com-Center shall have an Inupiat operator (“Com-Center operator”) on duty 24 hours per day from August 15, or one week before the start of the fall bowhead whale hunt in each respective village, until the end of the bowhead whale subsistence hunt in:

(A) Kaktovik for the Kaktovik Com-Center;

(B) Nuiqsut for the Deadhorse Com-Center;

(C) Barrow for the Barrow Com-Center;

(D) Wainwright for the Wainwright Com-Center.

(E) Pt. Lay for the Pt. Lay Com-Center, which will be located in the Pt. Lay Whaling Captains' Association building; and

(F) Pt. Hope for the Pt. Hope Com-Center, which will be located in the Pt. Hope Whaling Captains' Association building.

(2) All Com-Center staff shall be local hire.

(d) Duties of the Com-Center Operators.

(1) The Com-Center operators shall be available to receive radio and telephone calls and to call vessels as described below. A record shall be made of all calls from every vessel covered by Sections 207, 301, and 401 of this Agreement. Information reported regarding whales struck, lost, landed, or the location of whales struck, lost, or landed, or the number of strikes remaining, shall be confidential and shall not be disclosed to anyone other than the AEWC or the local Whaling Captains' Association. The record of all reporting calls should contain the following information:

(A) Industry Participant Vessel:

(i) Name of caller and vessel.

(ii) Vessel location, speed, and direction.

(iii) Time of call.

(iv) Anticipated movements between this call and the next report.

(v) Reports of any industry or subsistence activities.

(B) Subsistence Whale Hunting Boat:

(i) Name of caller.

(ii) Location of boat or camp.

(iii) Time of call.

(iv) Plans for travel.

(v) Any special information such as caught whale, whale to be towed, or industry vessel conflicts with whale or whaler. Any report of the number of whales struck, lost, or landed, or of the number of strikes remaining, shall be kept confidential and shall not be disclosed by the Com-Center or any Com-Center operator to anyone other than the AEWC or the local Whaling Captains' Association. The location of whales struck, lost, or landed shall be kept confidential and shall not be disclosed except to the extent needed to avoid an Industry/Subsistence Whale Hunter conflict.

(2) Report of Industry/Subsistence Whale Hunter Conflict. In the event an industry/subsistence whale hunter conflict is reported, the appropriate Com-Center operator shall record:

(A) Name of industry vessel.

(B) Name of subsistence whaling captain.

(C) Location of vessels.

(D) Nature of conflict, data, and time.

(3) If all vessels and boats covered by Sections 207, 301, and 401 of this Agreement have not reported to the appropriate Com-Center within one hour of the recommended time, that Com-Center operator shall attempt to call all non-reporting vessels to determine the information set out above under the Duties of the Com-Center operator.

(4) As soon as location information is provided by a vessel covered by Sections 207, 301, or 401 of this Agreement, the appropriate Com-Center operator shall plot the location and area of probable operations on the large map provided at the Com-Center.

(5) If, in receiving information or plotting it, a Com-Center operator observes that operations by Industry Participants might conflict with subsistence whaling activities, such Com-Center operator shall contact the industry vessel involved and advise the Industry Participant's Local Representative(s) and the vessel operators of the potential conflict.

SECTION 204. STANDARDIZED LOG BOOKS.

The Industry Participants will provide the Com-Centers and Marine Mammal Observer / Inupiat Communicators with identical log books to assist in the standardization of record keeping associated with communications procedures required pursuant to this Agreement.

SECTION 205. COMMUNICATIONS EQUIPMENT.

(a) Communications Equipment to be Provided to Subsistence Whale Hunting Crews.

(1) In General. The Industry Participants will provide (or participate in the provision of) the communications equipment described in paragraphs (4) and (6) of this subsection and subsection (b) of this section.

(2) Beaufort Sea. The Industry Participants funding Com-Centers in Deadhorse and Kaktovik will fund the provision of communications equipment for the whaling captains of Kaktovik and Nuiqsut in the same proportion as they fund those Com-Centers.

(3) Chukchi Sea. The Industry participants conducting operations in the Chukchi Sea will coordinate with each other to participate in funding the provision of communications equipment for the whaling captains of Barrow, Wainwright, Pt. Hope, and Pt. Lay.

(4) All-Channel, Water-Resistant VHF Radios.

These VHF radios are specifically designed for marine use and allow monitoring of Channel 16 while using or listening to another channel.

(A) Kaktovik Subsistence Whaling Boats: 8

(B) Kaktovik Base and Search and Rescue: 2

(C) Nuiqsut Subsistence Whaling Boats: 12

(D) Nuiqsut Base and Search and Rescue: 3

(E) Barrow Base and Search and Rescue: 2

(F) Wainwright Base and Search and Rescue: 2

(G) Wainwright Subsistence Whaling Boats: 4

(H) Pt. Hope Base and Search and Rescue: 2

(I) Pt. Hope Subsistence Whaling Boats: 10

(J) Pt. Lay Base and Search and Rescue: 2

(K) Pt. Lay Subsistence Whaling Boats: 4

(5) Specific VHF Channels For Each Village.

The whaling boats from each of the villages have been assigned individual VHF channels for vessel-to-vessel and vessel-to-Com-Center communications as follows:

(A) Nuiqsut whaling crews will use Channel 68.

(B) Kaktovik whaling crews will use Channel 69.

(C) Barrow whaling crews will use Channel 72.

(D) Wainwright Whaling Crews will use Channel 12.

(E) Pt. Lay Whaling Crews will use Channel 72.

(F) Pt. Hope Whaling Crews will use Channel 68.

(6) Satellite Telephones.

The satellite telephones are to be used as backup for the VHF radios. The satellite telephones for use on subsistence whaling boats are for emergency use only and should be programmed for direct dial to the nearest Com-Center.

A. Kaktovik Base Phones: 2

B. Kaktovik Subsistence Whaling Boats: 8

C. Nuiqsut Base Phones: 2

D. Nuiqsut Subsistence Whaling Boats: 12

E. Barrow Subsistence Whaling Boats: 2

F. Wainwright Subsistence Whaling Boats: 4

G. Pt. Lay Subsistence Whaling Boats: 2

(7) Distribution and Return of Equipment.

The distribution of the VHF radios and satellite telephone equipment to whaling captains for use during the 2011 fall bowhead subsistence whale hunting season shall be completed no later than August 15, 2011. All such units and telephone equipment provided under this Agreement, whether in this section or otherwise, will be returned promptly by the Subsistence Participants to the Industry Participant or the person providing such units and equipment at the end of each Village's 2011 fall bowhead whale subsistence hunt.

(b) Communications Equipment on Vessels Owned or Operated by the Industry Participants and/or their Contractors.

The Marine Mammal Observer / Inupiat Communicators onboard source vessels owned or operated by the Industry Participants and/or their contractors will also be supplied with all-channel VHF radios. The MMO/ICs have been assigned Channel 7 for their exclusive use in communicating with the Com-Center. Such radios shall be returned upon the completion or termination of the MMO/IC's assignment.

(c) Radio Installation and User Training.

The Whaling Captains of Nuiqsut, Kaktovik, Wainwright, Pt. Lay, and Pt. Hope, with assistance from the Industry Participants, will be responsible for the installation of the VHF radio equipment. The Industry participants will provide (or participate in the provision of) on-site user training for the VHF and satellite telephone equipment on or before August 15, 2011, if requested and as scheduled by the Whaling Captains' Associations of Nuiqsut, Kaktovik, Barrow, Wainwright, Pt. Lay, and Pt. Hope, and the Industry Participant operating the Beaufort Sea Com-Centers or Chukchi Sea Com-Centers**,** as appropriate.

SECTION 206. INDIVIDUALS TO CONTACT.

Listed below are the primary contact names and phone numbers for each of the Participants.

(1) Arctic Cable Company, LLC's Local Representative

TBD

(2) BP Exploration (Alaska), Inc.'s (BP) Local Representative

LOWRY BROTT will be BP's local representative on the North Slope during the Term of this Agreement and will be stationed at Northstar Island and will be available by telephone at (907) 670-3520 and when Mr. Brott is not available, his alternate, Jim Croak, will be stationed at Northstar Island and will be available by telephone at the above number.

(3) ENI's Local Representative

Hans Neidig (907) 865-3314

(4) Exxon Mobil's Local Representative

TBD

(5) ION / GX Technology's Local Representative

TBD

(6) Pioneer Natural Resources' (Pioneer) Local Representative

PAT FOLEY will be Pioneer's local representative during the Term of this Agreement and will be stationed in Anchorage and will be available by telephone at (907) 343-2110.

(7) Shell Offshore Inc.'s (Shell) Local Representatives

JOHN MAKETA and HOWARD HILL will be Shell's local representatives on the North Slope during the Term of this Agreement and will be stationed at Barrow during Chukchi Sea operations and at Deadhorse during Beaufort Sea operations and will be available by telephone at (907) 770-3700.

(8) STATOIL's Local Representative

TBD

(9) The Village of Kaktovik

For purposes of this Agreement, the individuals to contact for the Village of Kaktovik will be: JOSEPH KALEAK at (907) 640-6213 or 640-6515, and CHARLIE M. BROWER at (907) 640-4163 (home), (907) 640-2092 (work), or (907) 640-0052 (cell).

(10) The Village of Nuiqsut

For purposes of this Agreement, the individuals to contact for the Village of Nuiqsut will be: ISAAC NUKAPIGAK at (907) 480-6220 (Work); (907) 480-2400 (Home).

(11) The Village of Barrow

For purposes of this Agreement, the individuals to contact for the Village of Barrow will be: HARRY BROWER, JR. at (907) 852-0350 (Work), and EUGENE BROWER at (907) 852-3601.

(12) The Village of Wainwright

For purposes of this Agreement, the individuals to contact for the Village of Wainwright will be: ROSSMAN PEETOOK at (907) 763-4774, and WALTER NAYAKIK at (907)763-2915 (Work).

(13) The Village of Pt. Hope

For purposes of this Agreement, the individuals to contact for the Village of Pt. Hope will be: CHESTER FRANKSON, SR. at (907) 368-2054 (Home).

(14) The Village of Pt. Lay

For purposes of this Agreement, the individuals to contact for the Village of Pt. Lay will be: JULIUS REXFORD (907) 833-4592 (Home), (907) 833-2214 (Work), (907) 833-2320 (Fax), THOMAS NUKAPIAK (907) 833-6467 (Home), (907) 833-3838

(15) The AEWC

For purposes of this Agreement, the individuals to contact for the AEWC shall be: HARRY BROWER, JR. at (907) 852-0350 (Work) and JOHNNY AIKEN at (907) 852-2392.

SECTION 207. SUBSISTENCE WHALE HUNTING BOATS.

The following is a list of the number of boats each of the Subsistence Participants plan to use:

(1) Boats Owned/Used by Whaling Captains of Nuiqsut (NWCA)

The subsistence whaling crews of the Village of Nuiqsut plan to use (12) twelve boats for subsistence whale hunting during the late summer and fall of 2011.

(2) Boats Owned/Used by Whaling Captains of Kaktovik (KWCA)

The subsistence whaling crews of the Village of Kaktovik plan to use (8) eight boats for subsistence whale hunting during the late summer and fall of 2011.

(3) Boats Owned/Used by Whaling Captains of Barrow (BWCA)

The subsistence whaling crews of the Village of Barrow plan to use (40) forty boats for subsistence whale hunting during the late summer and fall of 2011.

(4) Boats Owned/Used by Whaling Captains of Wainwright (WWCA)

The subsistence whaling crews of the Village of Wainwright plan to use (4) four boats for subsistence whale hunting during the fall of 2011.

(5) Boats Owned/Used by Whaling Captains of Pt. Hope (Pt. HWCA)

The subsistence whaling crews of the Village of Pt. Hope plan to use (10) ten boats for subsistence whale hunting during the late fall of 2011.

(6) Boats Owned/Used by Whaling Captains of Pt. Lay (Pt. LWCA)

The subsistence whaling crews of the Village of Pt. Lay plan to use (4) four boats for subsistence whale hunting during the fall of 2011.

If any additional boats are put in use by subsistence whaling crews, the Industry Participants will be notified promptly through the Com-Center.

TITLE III – BARGE, TRANSIT, AND CABLE LAYING VESSEL OPERATIONS

SECTION 301. IN GENERAL.

A Participant may employ barges, transit, or cable laying vessels to transport materials or lay cable through the Beaufort Sea or Chukchi Sea during the term of this Agreement. Any Industry Participant who employs a barge or transit vessel to transport materials through the Beaufort Sea or Chukchi Sea during the term of this Agreement shall require the barge or transit vessel operator to comply with Sections 201, 205(b) and 302 of this Agreement while providing services to that Industry Participant.

SECTION 302. BARGE AND TRANSIT VESSEL OPERATIONS.

(a) Reporting Positions for Barge, Transit or Cable Laying Vessels Owned or Operated by industry Participants.

(1) All barge, transit. or cable laying vessels shall report to the appropriate Com-Center at least once every six hours commencing with a call at approximately 06:00 hours. Each call shall report the following information:

(A) Barge, transit, or cable laying vessel name, operator of vessel, charterer or owner of vessel, and the project or entity the vessel is transporting materials for.

(B) Barge, transit, or cable laying vessel location, speed, and direction.

(C) Plans for barge, transit, or cable laying vessel movement between the time of the call and the time of the next call. The final call of the day shall include a statement of the barge or transit vessel's general area of expected operations for the following day, if known at that time.

EXAMPLE: This is the Arctic Endeavor, operated by _____ for _____ in the Chukchi Sea. We are currently at ___'___ north ___'___ west, proceeding SE at ____ knots. We will proceed on this course for ___ hours and will report location and direction at that time.

(2) The appropriate Com-Center also shall be notified if there is any significant change in plans, such as an unannounced start-up of operations or significant deviations from announced course, and such Com-Center shall notify all whalers of such changes. A call to the appropriate Com-Center shall be made regarding any unsafe or unanticipated ice conditions.

(b) Operator Duties.

All barge, transit, or cable laying vessel operators are responsible for the following requirements.

(1) Monitoring VHF Channel 16. All barge and transit vessel operators shall monitor marine VHF Channel 16 at all times.

(2) Avoidance of Whale Hunting Crews and Areas. It is the responsibility of each Industry Participant and barge or transit vessel operator to determine the positions of their barge or transit vessels and to exercise due care in avoiding any areas where subsistence whale hunting is active.

(3) Vessel-to-Vessel Communication. After any barge or transit vessel owned or operated by any Industry Participant has been informed of or has determined the location of subsistence whale hunting boats in its vicinity**,** the Marine Mammal Observer / Inupiat Communicator shall contact those boats in order to coordinate movement and take necessary avoidance precautions.

(c) Routing Barge, Transit, and Cable Laying Vessels.

(1) All barge, transit, and cable laying vessel routes shall be planned so as to minimize any potential conflict with bowhead whales or subsistence whaling activities. All barges and transit vessels shall avoid areas of active or anticipated whaling activity, as reported pursuant to Section 202.

(2) Beaufort Sea. Vessels transiting east of Bullen Point to the Canadian border should remain at least five (5) miles offshore during transit along the coast, provided ice and sea conditions allow.

(3) Chukchi Sea. Vessels should remain as far offshore as weather and ice conditions allow, and at all times at least five (5) miles offshore during transit.

(d) Vessel Speeds.

Barge. transit, and cable laying vessels shall be operated at speeds necessary to ensure no physical contact with whales occurs, and to make any other potential conflicts with bowhead whales or whalers unlikely. Vessel speeds shall be less than 10 knots in the proximity of feeding whales or whale aggregations.

(e) Vessels Operating in Proximity of Bowhead Whales.

If any barge or transit vessel inadvertently approaches within 1.6 kilometers (1 mile) of observed bowhead whales, except when providing emergency assistance to whalers or in other emergency situations, the vessel operator will take reasonable precautions to avoid potential interaction with the bowhead whales by taking one or more of the following actions, as appropriate:

(1) reducing vessel speed to less than 5 knots within 900 feet of the whale(s);

(2) steering around the whale(s) if possible;

(3) operating the vessel(s) in such a way as to avoid separating members of a group of whales from other members of the group;

(4) operating the vessel(s) to avoid causing a whale to make multiple changes in direction; and

(5) checking the waters immediately adjacent to the vessel(s) to ensure that no whales will be injured when the propellers are engaged.

(f) Marine Mammal Sighting Data.

Industry Participants whose operations are limited exclusively to barge or vessel traffic will submit to the AEWC and NSB DWM all marine mammal sighting data.

TITLE IV – VESSELS, TESTING, AND MONITORING

SECTION 401. INDUSTRY PARTICIPANT VESSELS AND EQUIPMENT.

(a) List of Vessels and Equipment Required.

Each Industry Participant engaged in oil and gas operations shall provide a list identifying all vessels or other equipment (including but not limited to boats, barges, aircraft, or similar craft) that are owned and/or operated by, or that are under contract to the Industry Participants, for use in the Beaufort Sea or Chukchi Sea for oil and gas operations or for implementation of such Industry Participant's monitoring plan. Vessels and equipment used for oil and gas operations shall be listed in Attachment II, and vessels and equipment used for monitoring plans shall be listed in Attachment III.

(b) Only Listed Vessels and Equipment (or Like Vessels and Like Equipment) May Be Used.

(1) **NONE OF THE INDUSTRY PARTICIPANTS INTENDS TO OPERATE ANY VESSEL OR EQUIPMENT (EXCEPT FOR LIKE VESSELS OR LIKE EQUIPMENT) NOT IDENTIFIED IN THE LISTS REQUIRED UNDER SUBSECTION (a) DURING THE TERM OF THIS AGREEMENT.**

(2) Notwithstanding paragraph 1, if any Industry Participant decides to use different vessels or equipment or additional vessels or equipment, such vessels and equipment shall be used only for purposes identified in Attachments II or III; and the AEWC and the whaling captains of Nuiqsut, Kaktovik, Barrow, Wainwright, Pt. Hope, and Pt. Lay shall be notified promptly through the appropriate Com-Center, as identified in Section 203 of this Agreement, and in writing, of their identity and their intended use, including location of use.

SECTION 402. SOUND SIGNATURE TESTS.

(a) Sound Source Verification Testing.

(1) Geophysical Equipment. For purposes of obtaining a sound signature for Industry Participants' geophysical equipment, the Industry Participants shall have initiated a test of all geophysical equipment within 72 hours of initiating or having initiated operations in the Beaufort Sea or Chukchi Sea. Such tests shall be conducted as set forth in section 402(b).

(2) Vessels. For vessels engaged in geophysical activity, Industry Participants will conduct a sound source verification test for all geophysical equipment used for geophysical activity. Each Industry Participant shall establish a sound source verification range or Industry Participants may participate jointly in establishing a range for the Chukchi Sea and Beaufort Sea, or both. A separate range shall be used for the Chukchi Sea and Beaufort Sea, and vessels shall use the appropriate range for each sea in which they operate. For testing each vessel shall proceed through the range and record information on the date, time, vessel speed, vessel route, vessel load, weather conditions, and equipment operating on the vessel (all noise generating equipment on the vessel, other than geophysical equipment subject to separate testing under paragraph (1), shall be in operation while the vessel is proceeding through the range). The range should be established near a location where details on wind speed and direction are regularly monitored and archived.

(b) Mutual Agreement on Site for Testing; Advance Notice Required.

(1) In General. Each geophysical equipment sound signature test shall be conducted at a site mutually agreed upon by the Industry Participant conducting such test and the AEWC. Each Industry Participant conducting such sound signature test(s) will make a good faith effort to provide three (3) weeks advance notice to the AEWC and the NSB DWM of its intent to perform each test.

(2) Beaufort Sea Testing. For geophysical equipment sound signature tests conducted in the Beaufort Sea, the Industry Participant conducting such tests shall provide transportation for an appropriate number of representatives from: the AEWC, the whaling captains of the Villages of Barrow, Nuiqsut, and Kaktovik, and the NSB DWM to observe the sound signature tests.

(3) Chukchi Sea Testing. For geophysical equipment sound signature tests conducted on vessels to be used in the Chukchi Sea, the Industry Participant(s) conducting such tests shall provide transportation for an appropriate number of representatives from: the AEWC, the whaling captains of the Villages of Barrow, Wainwright, Pt. Lay, and Pt. Hope, and the NSB DWM to observe the sound signature tests.

(c) Sound Signature Data to be Made Available.

(1) Within fourteen (14) days of completing the sound signature field tests for geophysical equipment and within 30 days of the end of the operating season for sound source verification ranges, each Industry Participant and/or its contractor conducting such test(s) will make preliminary and final quality controlled results of the sound signature test(s) available upon request to the AEWC and the NSB DWM. The Industry Participant and/or its contractor will also provide the AEWC and the NSB DWM the preliminary analysis of that data, as well as any other applicable sound signature data that is available and that the AEWC, the NSB DWM, and the Industry Participant agree is relevant to understanding the potential noise impacts of the proposed operations to migrating bowhead whales or other affected marine mammals.

(2) Once completed the final data analysis will be provided to the AEWC and the NSB DWM upon request. The final data report for the sound source verification testing shall be provided to the NSB DWM and the AEWC no later than December 31, 2011.

(3) Any Industry Participant who prepares a model of the sound signature of its vessels and operations, whether before or after the sound signature test, will provide copies of those models and any related analysis to the AEWC and the NSB DWM upon request.

SECTION 403. MONITORING PLANS.

(a) Monitoring Plan Required.

(1) Each Industry Participant agrees to prepare and implement a monitoring plan to collect data designed to determine the potential effects of its oil and gas operations on fall migrating bowhead whales.

(2) The Monitoring Plans shall be designed in cooperation with the AEWC, the NSB DWM, NOAA Fisheries, and the Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE). If additional outside review is requested by any of the above entities, the Industry Participant will evaluate the request on a case by case basis.

(b) Beaufort Sea Monitoring Plans.

In the Beaufort Sea, the monitoring plans shall include an investigation of noise effects on fall migrating bowhead whales as they travel past the noise source, with special attention to changes in calling behavior, deflection from the normal migratory path, where deflection occurs, and the duration of the deflection.

(c) Chukchi Sea Monitoring Plans.

In the Chukchi Sea, the monitoring plans should focus on the identity, timing, location, and numbers of marine mammals and their behavioral responses to the noise source. The monitoring plans will place emphasis on understanding potential impacts from industrial sounds on bowhead whales.

(d) Use of Prior Information and Peer Reviewed Data.

(1) Prior impact study results shall be incorporated into the monitoring plans prepared by each Industry Participant as applicable.

(2) Each monitoring plan for oil and gas operations shall be subject to peer review by stakeholders on a peer review panel identified by NOAA Fisheries at the 2011 Open Water Season Peer Review Meeting, convened by NOAA Fisheries. Draft plans will be submitted to the NSB DWM and AEWC no later than two weeks prior to the 2011 Open Water Peer Review Meeting.

(e) Raw Data, Communication, and Summary Required.

(1) Each Industry Participant conducting site-specific monitoring will:

(A) after quality control reviews are completed, make electronic data, available to the NSB DWM at the end of the season.

(B) permit and encourage open communications among their contractors and the AEWC and NSB DWM.

(2) Each Industry Participant will submit a summary of monitoring plan results and progress to the AEWC and NSB DWM every two weeks during the operating season.

SECTION 404. CUMULATIVE NOISE IMPACTS STUDY.

Each Industry Participant further agrees to provide its monitoring plan and sound signature data, for use in a cumulative effects analysis of the multiple sound sources and their possible relationship to any observed changes in marine mammal behavior, to be undertaken pursuant to a Cumulative Noise Impacts Study.

The study design for the Cumulative Impacts Study shall be developed through a Cumulative Impacts Workshop to be organized by the North Slope Borough in the winter of 2011/2012. The results of this workshop will be presented at the 2012 Open Water Meeting.

TITLE V – AVOIDING CONFLICTS DURING THE OPEN WATER SEASON

Industry Participants are reminded that Sections 101(a)(5)(A) and (D) of the Marine Mammal Protection Act provide, among other things, that the Secretary can authorize the incidental taking of small numbers of marine mammals of a species or population stock if the Secretary finds, among other things, that the total of such takings during the authorized period **will not have an unmitigable adverse impact on the availability of such species or stock for taking for subsistence uses.**

The following Operating Guidelines apply in the Beaufort Sea and Chukchi Sea, except as otherwise specified and in all cases with due regard to environmental conditions and operational safety. These Operating Guidelines are in addition to any permit restrictions or stipulations imposed by the applicable governmental agencies.

SECTION 501. GENERAL PROVISIONS FOR AVOIDING INTERFERENCE WITH BOWHEAD WHALES OR SUBSISTENCE WHALE HUNTING ACTIVITIES.

(a) Routing Vessels and Aircraft.

(1) All vessel and aircraft routes shall be planned so as to minimize any potential conflict with bowhead whales or bowhead subsistence whaling activities. All vessels shall avoid areas of active or anticipated whaling activity (as reported pursuant to Section 202).

(2) Beaufort Sea. Vessels transiting east of Bullen Point to the Canadian border should remain at least five (5) miles offshore during transit along the coast, provided ice and sea conditions allow.

(3) Chukchi Sea. Vessels should remain as far offshore as weather and ice conditions allow, and at least five (5) miles offshore during transit.

(b) Aircraft Altitude Floor and Flight Path.

(1) AIRCRAFT SHALL NOT OPERATE BELOW 1500 FEET unless the aircraft is engaged in marine mammal monitoring, approaching, landing or taking off, or unless engaged in providing assistance to a whaler or in poor weather (low ceilings) or any other emergency situations. Aircraft engaged in marine mammal monitoring shall not operate below 1500 feet in areas of active whaling; such areas to be identified through communications with the Com-Centers.

(2) Except for airplanes engaged in marine mammal monitoring, aircraft shall use a flight path that keeps the aircraft at least five (5) miles inland until the aircraft is directly south of its offshore destination, then at that point it shall fly directly north to its destination.

(c) Vessel Speeds.

Vessels shall be operated at speeds necessary to ensure no physical contact with whales occurs, and to make any other potential conflicts with bowhead whales or whalers unlikely. Vessel speeds shall be less than 10 knots in the proximity of feeding whales or whale aggregations.

(d) Vessels Operating in Proximity of Bowhead Whales.

If any vessel inadvertently approaches within 1.6 kilometers (1 mile) of observed bowhead whales, except when providing emergency assistance to whalers or in other emergency situations, the vessel operator will take reasonable precautions to avoid potential interaction with the bowhead whales by taking one or more of the following actions, as appropriate:

(1) reducing vessel speed to less than 5 knots within 900 feet of the whale(s);

(2) steering around the whale(s) if possible;

(3) operating the vessel(s) in such a way as to avoid separating members of a group of whales from other members of the group;

(4) operating the vessel(s) to avoid causing a whale to make multiple changes in direction; and

(5) checking the waters immediately adjacent to the vessel(s) to ensure that no whales will be injured when the propellers are engaged.

SECTION 502. GEOPHYSICAL ACTIVITY LIMITATIONS.

The following operating limitations are to be observed and the operations are to be accompanied by a monitoring plan as set forth in Section 403 and Attachment III of this Agreement. The Industry Participants conducting geophysical activity agree to coordinate the timing and location of such activity so as to reduce, by the greatest extent reasonably possible, the level of noise energy entering the water from such activity at any given time and at any given location.

(a) Limitations on Geophysical Activity in the Beaufort Sea.

All geophysical activity in the Beaufort Sea shall be conducted in accordance with the terms set forth below.

(1) Kaktovik: No geophysical activity from the Canadian Border to the Canning River (146 deg. 4 min. W) from 25 August to close of the fall bowhead whale hunt in Kaktovik and Nuiqsut.[1] From August 10 to August 25, Industry Participants will communicate and collaborate with AEWC on any planned vessel movement in and around Kaktovik and Cross Island to avoid impacts to whale hunt.

[1] The bowhead whale subsistence hunt will be considered closed for a particular village when the village Whaling Captains' Association declares the hunt ended or the village quota has been exhausted (as announced by the village Whaling Captains' Association or the AEWC), whichever occurs earlier.

(2) Nuiqsut:

A. Pt. Storkerson(~148 deg. 42 min. W) to Thetis Island (~150 deg. 10.2 min. W)**.**

(i) *Inside the Barrier Islands*: No geophysical activity prior to August 5. Geophysical activity is allowed from August 5 until completion of operations[2]

(ii). *Outside the Barrier Islands:* No geophysical activity from August 25 to close of fall bowhead whale hunting in Nuiqsut. Geophysical activity is allowed at all other times.

b. Canning River (~146 deg. 4 min. W) to Pt. Storkerson (~148 deg. 42 min. W): No geophysical activity from August 25 to the close of bowhead whale subsistence hunting in Nuiqsut.

(3) Barrow: No geophysical activity from Pitt Point on the east side of Smith Bay (~152 deg. 15 min. W) to a location about half way between Barrow and Peard Bay (~157 deg. 20 min. W) from September 15 to the close of the fall bowhead whale hunt in Barrow.

[2] Geophysical activity allowed in this area after August 25 shall include a source array of no more than 12 air guns, a source layout no greater than 8 m x 6 m, and a single source volume no greater than 880 in^3.

(b) Limitations on Geophysical Activity in the Chukchi Sea.

All geophysical activity in the Chukchi Sea shall be conducted in accordance with the terms set forth below.

(1) Beginning September 15, and ending with the close of the fall bowhead whale hunt,[3] if Wainwright, Pt. Lay, or Pt. Hope intend to whale in the Chukchi Sea, no more than two geophysical activities employing geophysical equipment will occur at any one time in the Chukchi Sea. During the fall bowhead whale hunt, geophysical equipment will not be used by Participants within 30 miles of any point along the Chukchi Sea coast. Industry Participants will contact the Whaling Captains' Associations of each of those villages to determine if a village is prepared to whale and will notify the AEWC of any response.

(2) Safe harbor will be at sites selected by the Industry Participants and the AEWC. Safe harbor sites will be agreed upon no later than the beginning of operations and shall be listed in Attachment IV. However, a vessel captain will seek safety for his assets (vessel and personnel) as is his duty under the Law of the Sea.

(3) Any vessel operating within 60 miles of the Chukchi Sea coast will follow the communications procedures set forth in Title II of this Agreement. All vessels will adhere to the conflict avoidance measures set forth in Section 501 of this Agreement.

(4) If a dispute should arise, the resolution process set forth in Section 106 of this Agreement shall apply.

[3] The bowhead whale subsistence hunt will be considered closed when village Whaling Captains' Associations of Wainwright, Pt. Lay, and Pt. Hope have each declared that (A) they do not intend to hunt, (B) their village hunt has ended, or (C) the village quota has been exhausted (as announced by the village Whaling Captains' Association or the AEWC), whichever occurs earlier.

SECTION 503. DRILLING AND PRODUCTION.

For exploratory drilling and production between 144 deg. W and the Canning River (~146 deg. 4 min. W), zero discharge of:

(1) drilling fluids;

(2) cuttings after 20” casing;

(3) treated sanitary and gray water; and

(4) ballast and bilge water.

(b) Drilling Operations in the Beaufort Sea East of Cross Island.

No drilling equipment or related vessels used for at-sea oil and gas operations shall be onsite at any offshore drilling location east of Cross Island from 25 August until the close of the bowhead whale hunt in Nuiqsut and Kaktovik. However, such equipment may remain within the Beaufort Sea in the vicinity of 71 degrees 25 minutes N and 146 degrees 4 minutes W., or at the edge of the Arctic ice pack, whichever is closer to shore.

(c) Drilling Operations in the Beaufort Sea West of Cross Island.

In 2011, no drilling equipment or related vessels used for at-sea oil and gas operations shall be moved onsite at any location outside the barrier islands west of Cross Island until the close of the bowhead whale hunt in Barrow.

SECTION 504. SHORE-BASED SERVICE AND SUPPLY AREAS.

Shore-based service and supply areas used by Industry Participants shall be located and operated so as to ensure compliance with the terms of this Agreement.

TITLE VI – LATE SEASON SEISMIC OPERATIONS

SECTION 601. IN GENERAL.

Any Industry Participant who engages exclusively in geophysical activities that are conducted at least 5 miles or more from the Alaska coast in the Beaufort Sea or Chukchi Sea and begin on or after October 1, 2011 shall comply with Sections 201, 205(b), 502(a), and 602 of this Agreement.

SECTION 602. VESSEL OPERATIONS.

(a) Reporting Positions When Vessels Come Within 40 Miles of the Coast.

(1) A vessel subject to this section operating within 40 miles of the Alaska coast shall report to the appropriate Com-Center at least once every six hours commencing with a call at approximately 06:00 hours. Each call shall report the following information:

(A) Vessel name, operator of vessel, charter or owner of vessel, and the project or entity the vessel is conducting operations for.

(B) Vessel location, speed, and direction.

(C) Plans for vessel movement between the time of the call and the time of the next call. The final call of the day shall include a statement of the vessel's general area of expected operations for the following day, if known at that time.

EXAMPLE: This is the Arctic Endeavor, operated by _____ for _____ in the Chukchi Sea. We are currently at ___'___ north ___'___ west, proceeding SE at ____ knots. We will proceed on this course for ___ hours and will report location and direction at that time.

(2) The appropriate Com-Center also shall be notified if there is any significant change in plans, such as an unannounced start-up of operations or significant deviations from announced course, and such Com-Center shall notify all whalers of such changes. A call to the appropriate Com-Center shall be made regarding any unsafe or unanticipated ice conditions.

(b) Operator Duties.

All vessel operators subject to this title are responsible for the following requirements.

(1) Monitoring VHF Channel 16. All vessel operators shall monitor marine VHF Channel 16 at all times.

(2) Avoidance of Whale Hunting Crews and Areas. It is the responsibility of each Industry Participant and vessel operator to determine the positions of their vessels and to exercise due care in avoiding any areas where subsistence whale hunting is active.

(3) Vessel-to-Vessel Communication. After any vessel owned or operated by any Industry Participant has been informed of or has determined the location of subsistence whale hunting boats in its vicinity**,** the Marine Mammal Observer / Inupiat Communicator shall contact those boats in order to coordinate movement and take necessary avoidance precautions.

(c) Routing Vessels.

(1) All vessel routes within 40 miles of the Alaska coast shall be planned so as to minimize any potential conflict with bowhead whales or subsistence whaling activities. All vessels shall avoid areas of active or anticipated whaling activity, as reported pursuant to Section 202.

(2) Beaufort Sea. Vessels transiting east of Bullen Point to the Canadian border should remain at least five (5) miles offshore during transit along the coast, provided ice and sea conditions allow.

(3) Chukchi Sea. Vessels should remain as far offshore as weather and ice conditions allow, and at all times at least five (5) miles offshore during transit.

(d) Vessel Speeds.

Vessels shall be operated at speeds necessary to ensure no physical contact with whales occurs, and to make any other potential conflicts with bowhead whales or whalers unlikely. Vessel speeds shall be less than 10 knots in the proximity of feeding whales or whale aggregations.

(e) Vessels Operating in Proximity of Bowhead Whales.

If any barge or transit vessel inadvertently approaches within 1.6 kilometers (1 mile) of observed bowhead whales, except when providing emergency assistance to whalers or in other emergency situations, the vessel operator will take reasonable precautions to avoid potential interaction with the bowhead whales by taking one or more of the following actions, as appropriate:

(1) reducing vessel speed to less than 5 knots within 900 feet of the whale(s);

(2) steering around the whale(s) if possible;

(3) operating the vessel(s) in such a way as to avoid separating members of a group of whales from other members of the group;

(4) operating the vessel(s) to avoid causing a whale to make multiple changes in direction; and

(5) checking the waters immediately adjacent to the vessel(s) to ensure that no whales will be injured when the propellers are engaged.

(f) Marine Mammal Sighting Data.

Industry Participants whose operations are subject to this title will submit to the AEWC and NSB DWM all marine mammal sighting data.

TITLE VII – PARTICIPANTS

This Agreement shall be binding and effective when signed by the duly authorized representatives of the Participants. Signatures may be by facsimile on separate pages.

R. Lee Bruce
Senior Project Manager
Point Thomson Project

ExxonMobil

November 17, 2009

Mr. Dan Forster
Director, Planning Department
North Slope Borough
Post Office Box 69
Barrow, Alaska 99723-0069

Dear Dan,

We are pleased to transmit the ExxonMobil Point Thomson Project Oil Spill Contingency Mitigation Agreement to the North Slope Borough (NSB), Inupiat Community of the Arctic Slope, Alaska Eskimo Whaling Commission, Kaktovik and Nuiqsut. The Agreement represents ExxonMobil's commitment to provide aid as quickly and simply as possible to residents of Kaktovik, Nuiqsut or other affected communities in the event of a spill preventing access to subsistence resources.

An account has been established at Wells Fargo Bank with an independent letter of credit in the amount of $25 million. In the event of a spill, the account can be promptly activated by appointment of an Administrator by the Mayor of the NSB and confirmation of the Administrator's appointment by ExxonMobil to Wells Fargo. No other action or prior approval by ExxonMobil is necessary. The fund would then be immediately available to the Administrator to respond to requests for assistance.

ExxonMobil is committed to preventing any incident which would cause a major oil spill and anticipates this agreement will not have to be implemented. But, if needed, we expect and intend the Agreement will work to make assistance available without delay. We believe this Agreement represents the best procedure for accessing assistance.

We appreciate the comments we received from NSB counsel and our discussions with the Planning Department and others last summer. At that time we provided a draft of the agreement to ICAS, the AEWC, and the cities of Kaktovik and Nuiqsut. The Agreement reflects the comments suggested. We welcome acknowledgment of the Agreement by other parties as provided on the signature page. Our commitment to the Agreement is unconditional.

We appreciate the continued support of the NSB and neighboring communities for the Point Thomson Project. Please let us know if you have any questions or if we can provide any further information.

Sincerely,

R. Lee Bruce
Senior Project Manager
Point Thomson Project
On Behalf of Exxon Mobil Corporation

EXXONMOBIL POINT THOMSON PROJECT
OIL SPILL CONTINGENCY MITIGATION AGREEMENT

THE POINT THOMSON PROJECT

The ExxonMobil Point Thomson Project location is about 60 miles west of the community of Kaktovik and about 110 miles east of the community of Nuiqsut. The Project is about 25 miles east of existing facilities at Badami and 50 miles east of Prudhoe Bay.

The Point Thomson Project facilities are located onshore. ExxonMobil will access the offshore portions of the deep underground reservoir from onshore locations utilizing directional drilling.

Drilling of wells is underway. Production will commence in 2014. At that time, the Project is to include three onshore drilling pads with related infrastructure. An export pipeline will transport liquid hydrocarbons to the Trans Alaska Pipeline.

The Project does not include a gravel road from Prudhoe Bay. Winter access to the Project location will be by seasonal ice road. During the open water season equipment and supplies including fuel will be barged to Point Thomson. ExxonMobil has voluntarily elected to suspend barging operations during the subsistence whale hunt of Kaktovik and Nuiqsut, and no barging is planned during whaling season.

THE IMPORTANCE OF SUBSISTENCE AND BOWHEAD WHALES

ExxonMobil recognizes the critical importance of subsistence to meet the nutritional needs of the Inupiat people of the North Slope. The company also recognizes that subsistence is at the core of the cultural values and well-being of the Inupiat people. In particular, ExxonMobil understands that, for many centuries, the bowhead whale has been central to the subsistence, culture, and tradition of the Inupiat.

ExxonMobil is committed to prevent any incident or impact which might disrupt or deplete subsistence hunting or resources, especially the bowhead whale. Should any such incident nevertheless occur, ExxonMobil is committed to minimize its effect on the people of Kaktovik, Nuiqsut, and any other affected community.

OIL SPILL CONTINGENCY MITIGATION

To demonstrate its commitment, ExxonMobil adopts this Oil Spill Contingency Mitigation Agreement ("Agreement"). The purpose of this Agreement, in cooperation with the Community, is to establish a contingency plan to mitigate subsistence impacts of a spill to marine waters of the central and eastern Beaufort Sea (and larger area should that be impacted) as a result of the Point Thomson Project.

For purposes of assistance which may be provided under this Agreement, the Community will be considered to comprise the City of Kaktovik and the City of Nuiqsut, acting on behalf of their residents, and, as may be appropriate under sections 1.A and B, any other affected city. For purposes of consultation and assistance in administration under this Agreement, the Community shall also include the North Slope Borough, the Alaska Eskimo Whaling Commission, and the Inupiat Community of the Arctic Slope.

This Agreement shall remain in effect at all times while activities permitted under North Slope Borough permits 09-105 through 109 or subsequent amendments are ongoing, and shall be subject to renewal as appropriate.

This Agreement is not intended to relieve ExxonMobil from any additional liability it may incur from its acts or omissions associated with the Point Thomson Project.

I. TRIGGER MECHANISMS FOR IMPLEMENTATION OF ASSISTANCE

A. Oil Spill Defined

For the purpose of this document, an "oil spill" is a discharge (as defined in 33 USC § 2701(7)) of liquid hydrocarbons (including crude oil and diesel fuel) into waters of the Beaufort Sea, irrespective of cause, including Acts of God, that causes oil to be present in the water, including ice and broken ice, and

1. Either physically prevents access to subsistence resources by the Community, or
2. Has the significant potential to adversely affect bowhead whales and their habitat, or other species harvested for subsistence use, and is followed by a reduction in the availability of those species for subsistence use in areas where they are traditionally hunted, as determined within three years of the oil spill.

Assistance under Part I.A.1 shall be implemented in the event of a spill upon request of the mayors of Kaktovik, Nuiqsut, or any other affected city to the Administrator appointed under Section II.D.

Assistance under Part I.A.2 shall be implemented in the event of a spill upon request of the mayors or Kaktovik, Nuiqsut, or any other affected city and upon a determination by an independent expert that the requirements of Part I.A.2 are met. The independent expert shall be selected by ExxonMobil and the Community. If an independent expert is not mutually selected, the Community will provide ExxonMobil with a list of three experts not a resident of an affected city and ExxonMobil will select from this list. This determination shall include whether the impacts identified are to the Community as defined in this document (the geographic area of the central and eastern Beaufort Sea) or broader. This determination may be made in sequential steps as the spill impacts and oil spill response evolves. This determination is intended solely as a mechanism to implement the assistance provided for in this Agreement. It is not intended, and shall not be construed, as a scientific finding or admission by any party.

B. Impacts Beyond the Central and Eastern Beaufort Sea

If the determination is made under Part I.A. 2 of this document that the impacts are broader than the central and eastern Beaufort Sea and affect additional Inupiat bowhead whale communities, those impacted communities will be included under this Agreement.

II. IMPLEMENTATION

A. Financial Assurance Instrument

ExxonMobil shall maintain a financial assurance instrument that is available to meet ExxonMobil's commitments. The financial assurance instrument shall be a bond or similar secured instrument of ExxonMobil's choice made payable to the Custodian, for the benefit of the Community, and disbursed to the Community upon request by the Administrator in accordance with the provisions of this Part II. This bond or other similar financial instrument (e.g., a letter of credit) shall be in the amount of $25 million (25 Million Dollars). This shall serve as the level of financial assurance unless ExxonMobil and the Community mutually agree that additional funds may be necessary to mitigate the adverse impacts of an oil spill or when impacts occur that may likely deplete and exceed the initial funds available from the financial assurance instrument. The amount of the instrument shall be adjusted every three years to account for inflation and/or changes in the consumer price index.

B. Custodian

ExxonMobil and the Community select Wells Fargo Bank N.A. as the Custodian. At any time ExxonMobil and the Community may mutually agree to select a different Custodian. At no time shall the Custodian be affiliated with or in any way subject to the influence of the ExxonMobil or the Community.

C. Alternate Custodian

If the Custodian at any time is unable or unwilling to perform the duties required by this Agreement, ExxonMobil and the Community shall select an alternate Custodian.

D. Administration and Disbursement of Funds

In the event of a request for assistance under Part I of this document, or at any time which may otherwise be appropriate, the Mayor of the North Slope Borough, in consultation with ExxonMobil, the Mayors of the Cities of Kaktovik and Nuiqsut, the Alaska Eskimo Whaling Commission and the Inupiat Community of the Arctic Slope, shall appoint a senior official in the NSB administration or independent management consultant with necessary support staff to act as Administrator to request and receive funds from the Custodian. The Administrator shall report directly to the Mayor of the North Slope Borough.

Duties of the Administrator as directed by the Mayor of the North Slope Borough may include:

1. Receive Community requests for funds and verify conformance with the purposes for which funds may be requested as described in Part II.E;
2. Request and obtain release of funds from the Custodian and disburse funds to the Community;
3. Manage in cooperation with the Community the implementation of the mitigation described in Part II.E; and
4. Document and account for the funds disbursed according to standard accounting practices.

The Custodian shall release funds as requested in writing by the Administrator. These funds shall be disbursed by the Administrator to the Community to pay for the costs of mitigation as described in Part II.E. The specific disbursement of funds is at the discretion of the Administrator as delegated by the Mayor of the North Slope Borough. These expenditures and documentation shall be subject to audit by ExxonMobil.

E. Purposes for the Disbursement of Funds

The Administrator shall request funds from the Custodian for the following purposes:

1. Transportation required to relocate subsistence hunters and their equipment to alternate hunting sites and to safely return the hunters, their equipment and subsistence catch to their villages.

2. Acquisition of alternate subsistence food supplies to replace subsistence resources that are otherwise unavailable and transportation of food supplies to their designated destination.

3. Reimbursement of funds expended by whaling captains in preparation for a whaling season that has been curtailed by an oil spill.

4. Counseling and cultural assistance for Community residents to handle disruptions to their lives and culture.

5. Assistance for the Alaska Eskimo Whaling Commission to restore the International Whaling Commission subsistence whaling quota for the Community in the event it is affected by an oil spill.

6. Administrative costs incurred by the Administrator related to fulfill the functions described in Part II.D.

7. Any other purposes agreed by the Community and ExxonMobil.

III. DISPUTES

A. Dispute Resolution

If a dispute arises between ExxonMobil and the Community regarding any issue relating to implementation of this Agreement that cannot be resolved through good faith negotiations within 20 days of written notice of the dispute in writing, the dispute shall be resolved through mediation by an independent third party selected by ExxonMobil and the Community. If ExxonMobil and the Community cannot agree on the mediator, the Community will provide a list of three qualified independent mediators from which ExxonMobil will select one. Resolution of the dispute by the third party shall be conclusive. ExxonMobil will bear the cost of mediating any and all disputes.

B. Disputed Request for Funds

In the event of a dispute between the Community and ExxonMobil regarding the necessity for any request of funds made by the Community under this Agreement, the request for funds shall be processed by the Custodian under Section II.D in a timely fashion notwithstanding such dispute, subject to reimbursement as set forth in this Agreement.

C. Reimbursement of Funds

If a request for and disbursement of funds is determined to be inappropriate under the procedures set forth in Part III.A, the Community shall reimburse the Custodian in full within 30 days of the date of such determination.

INTRODUCTION

A gravel mine site is required to supply an estimated 2.25 million cubic yards of gravel for the Point Thomson Project (Project). This project consists of placing gravel for three oil/gas production pads, an airstrip, 12 miles of infield roads, gravel stockpile for future road and pad maintenance, and several ancillary pads.

The mine site preparation, operation, subsequent closure and rehabilitation will occur over several years and will be done in a manner that minimizes the extent of tundra disturbance at the site. Once the mine site excavation naturally fills with water, it will provide shallow water habitat for birds and deep-water habitat for fish. The mine could also be used as a water source for ice roads or as a backup for the C-1 Pit Water Source for the Project.

The Point Thomson mine site includes an excavation area anticipated to be approximately 49.6 acres, access roads and 12.9-acre gravel stockpile. Additional working areas will include seasonal ice pads (Figure 1).

- Page Intentionally Left Blank -

MINE SITE LOCATION SELECTION CRITERIA

The proposed Point Thomson mine site is located approximately 20 miles east of the Badami Production Facility (Figure 1). Within the Project area, it is generally located northeast of the proposed airstrip positioned between the proposed Central Pad Road and B Creek (Stream 24). Access to the site will be from the Central Pad Road (Figure 2).

This site was chosen for the following characteristics:

- Close to the in-field road system to minimize access road length and length of connecting ice roads during construction;
- Close to desired pads and airstrip to reduce transportation needs and impacts;
- Minimal overburden depth to minimize size of gravel mine;
- Absence of significant ground ice;
- Suitable gravel quality and quantity;
- Avoid impacts to higher value wetlands (location is on higher ground); and
- Minimize wetlands footprint while meeting gravel quantity requirements.

A preliminary geotechnical characterization of the material source was conducted in 2001. The Project obtained additional geotechnical information at this site in 2010 and 2011 to confirm available gravel quality and quantities and further define the mine site configuration. Figure 2 provides the planned layout of the proposed mine site including access roads, gravel stockpile and seasonal ice pads.

- Page Intentionally Left Blank -

MINING PLAN

General

The mine site will provide gravel to accomplish the construction of new gravel facilities for the Project. The gravel will be mined from the site over two years primarily during the winter season. Before the mine site is closed out, a stockpile of gravel will be created adjacent to the excavated area to provide gravel required for facility maintenance.

The excavated gravel areas for years one and two are shown in Figures 3 through 6. The tundra and overburden overlaying the excavated area will be moved adjacent to the excavation and temporarily stored on seasonal ice pads in stockpiles to the south of the excavation or within the excavated area. The gravel stockpile will be constructed to the west of the excavation. The mined area is expected to provide approximately 2.25 million cubic yards of gravel and yield approximately 1,042,000 cubic yards of overburden over the two years of operation.

The site will be accessed by ice road during the construction of the Point Thomson facilities. Following season one mining activities, access via the newly-constructed Central Pad Road will be available for transport within the Point Thomson area.

Winter Mining Plan

Mining operations are planned during the winter months and include the preparation of gravel access roads and staging areas for equipment near the mine site. The intent is to locate the excavated area as close as practicable to the proposed road system to minimize the environmental impact and provide optimal access for gravel mining operations and access to the gravel stockpile during operations.

Examination of the area surrounding the proposed excavation area suggests that the permafrost is uniform with little thermokarst or ice polygon features. Based on the geotechnical investigations, significant solid ice features that could thaw and erode into the excavated area are not expected.

Mining operations will commence with survey and staking followed by overburden stripping. It is anticipated that an average 10 feet overburden layer will be removed from the excavated area. The organic or active layer (approximately 2 ft. thick) will be removed and stockpiled separately from the inorganic layer. The depth of the organic layer will be confirmed by visual inspection during stripping operations. During mining activities, the overburden will be temporarily stockpiled on seasonal ice pads or, if operationally possible, placed within the mine footprint.

Mining operations will include blasting and mechanical excavation to a depth of approximately 40 feet below the bottom of the overburden layer.

Access ramps will be constructed into the excavated area as mining progresses deeper into the excavated area. Road access to the excavated area will be on the north and south sides of the excavation. The road gradient into the excavated area will not exceed an 8% gradient and will typically be 5%. Mined gravel will be transported from the mine

site to the various facilities via a combination of gravel roads, and ice roads, while under construction. The excavated area sidewalls will be stepped as shown in Figures 4 and 6.

Summer Mining Plan

While mining will primarily occur during the winter, summer mining activities may also occur. If summer mining is required following winter mining activities, mechanical equipment (e.g., trimmer, dozer) will be used for gravel excavation activities in the mine footprint. No blasting will occur during summer mining activities. No direct placement of gravel on tundra during the summer is planned.

REHABILITATION PLAN

Introduction

This plan describes methods and procedures proposed for rehabilitating the Point Thomson mine site. The plan may be amended as site-specific information is available and as rehabilitation progresses over time. Target revegetation performance standards are listed in Table 1, and the proposed monitoring schedule is listed in Table 2.

The Project mine site rehabilitation plan is to place stockpiled overburden back into the excavated area, creating stable sidewalls and a mosaic of wet and moist habitat conditions. The excavated area will be allowed to fill with snowmelt and spring runoff from the surrounding area and is expected to take from 5-10 years to fill with water. The flooded mine site will then serve as a potential back-up water source for Point Thomson Project future activities.

Surrounding Vegetation

Topography surrounding the Point Thomson mine site is relatively flat with minimal relief. The vegetation is wet and moist tundra dominated by *Eriophorum angustifolium* and *Carex aquatilis*. *Arctophila fulva* may be present in wetter areas and shallow flooded habitats. *Dupontia fischeri* is often locally prevalent, and in drier areas tussock tundra dominated by *Eriophorum vaginatum* may also occur. A preliminary assessment of specific site conditions and vegetation types within the mining footprint will be completed prior to mining activities.

Rehabilitation Methodology

Mining is planned over two years, primarily during the winter season. Steps towards rehabilitation will be completed each year after winter mining operations cease. The planned configuration of the area is shown in Figure 5.

After mining is complete, inorganic overburden will be placed over the stepped benches in the excavated sidewalls to form side slopes whose natural angle of repose is expected to be between 2:1 and 3:1 H:V, as shown in Figures 3 through 6. These side slopes would be consistent with other material sites in the Prudhoe Bay Unit and Kuparuk Unit. The remaining inorganic overburden will be used to create the littoral shelf on the east end of the mine. Organic overburden will be placed on the inorganic overburden to improve conditions for revegetation.

Topography of the mine perimeter and littoral shelf is expected to be irregular thereby providing a range of potential soil moisture and habitat conditions. This irregularity is to be achieved by depositing truckloads of overburden randomly over the upper areas of the 3:1 slopes and the littoral shelf along the east end of the mine.

Following the first winter of mining activities, inorganic overburden will be removed from the seasonal ice pad and placed in the excavated mined area and sidewalls to begin construction of the littoral shelf on the east edge of the mine. Material for the littoral shelf

will be overbuilt above grade to account for settling. A berm will be created to minimize potential spring flooding into the mine from nearby B Creek (Stream 24) during excavation activity. Organic overburden from year one will also be removed from the seasonal ice pad and stockpiled separately on the littoral shelf for use after mining operations are completed in the second year.

After the second year of mining additional overburden generated during the second year of mining will be placed on the sidewalls and used to expand and sculpt the littoral shelf along the east edge of the mine. The organic overburden will be used on the littoral shelf as a cap, and to create irregular surfaces that enhance shallow water habitat.

Backfilled material will be allowed to settle for at least one year before seeding and/or other revegetation efforts are applied. Anticipated site conditions will guide initial revegetation efforts, however, additional or alternative treatments will be considered as actual conditions are observed throughout the planned monitoring schedule described below.

The excavated mine site will be allowed to fill naturally with melted accumulated snow and spring runoff from the surrounding area. Once filled with water, the mine site can be used as a backup (secondary) source of water for ice roads and for the operations camp. The gravel access road to the mine site will allow future access to the water source.

This rehabilitation plan is based upon existing site information and assumes the most appropriate use of the mine site at closure is wildlife habitat (primarily for birds). This plan will be implemented, as appropriate, based upon final site conditions at abandonment. Should a change in construction plans require some additional mining of gravel or expansion of the mine beyond the second year, the mine may be left open and the rehabilitation completed when appropriate. In this case, a revised rehabilitation plan would be submitted to the regulatory agencies consistent with existing Federal and State permitting requirements and established North Slope practice.

Goals and Objectives

The short-term objective is to re-use the excavated overburden material to stabilize the side slopes of the mine and create areas of both deep and shallow water habitats. Re-use of the organic overburden is expected to provide a suitable substrate with adequate soil nutrients and texture to support revegetation. The use of temporary ice pads to stockpile overburden during mining operations is expected to have a limited impact on the underlying vegetation and reduce the cumulative mining footprint in the long-term. The overall goal of the mine rehabilitation is to create a mosaic of habitat types. The excavated pit will provide deep-water habitat for fish. The littoral shelf is expected to provide areas of shallow water and wet and moist soil conditions that will eventually support vegetative communities similar to those in the surrounding tundra. The variety of conditions would support complex food web structuring and improve suitability for a variety of waterfowl and other wildlife.

Rehabilitation Treatments

Terrestrial areas outside or along the perimeter of the mine will be seeded with indigenous grasses. *Puccinellia borealis* is a native grass that is often observed as a primary colonizer on disturbed sites. This grass typically dies out several years after reaching maturity and gives way to other colonizing species. *P. borealis* seed is available in limited quantities. Depending on availability, other species may be considered, or fertilizer treatments alone may be applied.

In the Prudhoe Bay and Kuparuk region, a balanced fertilizer application of 10-20-20 Nitrogen Phosphorus Potassium is commonly used to encourage revegetation and establishment of seeded species on disturbed sites. Soils in the Point Thomson region are slightly more acidic than those closer to Prudhoe Bay. This characteristic may have some influence on final species composition; however, available soil nutrients and potential deficiencies are expected to be similar in the Project area to those in the Prudhoe and Kuparuk region. Based on experience across the North Slope, phosphorous is typically the limiting nutrient in soils for this region. An application of about 60 lbs./acre of phosphorous alone is often sufficient to encourage natural colonization from the surrounding plant communities (BPXA et al., 2004). Site-specific conditions including the areal extent of disturbance and surrounding community types, and/or soil nutrient analyses will ultimately determine the appropriate application of fertilizer.

In wet and/or shallowly flooded areas, transplanting (sprigging) of indigenous species will be used to improve habitat conditions. *Actophila fulva* is an indigenous grass that provides quality habitat for many species of birds. Sprigging *A. fulva* has been successful at many areas around Prudhoe Bay and at the Badami mine site overburden stockpile where artificial ponds were created. This species is capable of establishing and reproducing under a variety of soil moisture conditions ranging from terrestrial to shallow flooded zones. Other aquatic species including *Hippuris vulgaris* and *Ranunculus spp*. have also been successfully transplanted to improve aquatic habitat conditions. Ultimately, the availability of species found in the surrounding communities will determine those selected for transplanting at the mine site. Fertilizer is beneficial to the establishment of transplanted species; however, if the mine site may be used as a secondary water source for the Project, fertilizer would not be applied unless adequate water quality standards can be assured (Alaska Water Quality Standards [18 AAC 70] of 1 mg/L nitrites, and 10 mg/L total nitrate and nitrite).

Performance Standards

By the tenth year following the application of cultivation treatments terrestrial areas will be expected to support at least 10% total live vascular cover (TLVC) comprised of at least five naturally colonizing species with 0.2% cover each. These performance standards should lead to a stabilizing plant cover on the site while also promoting eventual replacement of seeded grasses with naturally colonizing species. These standards do not apply to areas that are ponded for more than four weeks during the

growing season. Transplanted species are expected to persist, but there will be no quantitative performance standard associated with these species (Table 1).

Monitoring for Performance Standards

Monitoring will be used to evaluate progress towards the performance standards in accordance with Table 2.

Revegetation of terrestrial areas will be monitored using a point intercept sampling technique along a fixed transect. Aquatic areas will be monitored using repeat photography from established photo-point locations. If intermediate sampling and monitoring indicates that progress of revegetation is not sufficient to meet the proposed standards, additional remedial actions may be considered to increase plant cover. Final monitoring will determine whether the revegetation performance standards have been met.

Reporting

Progress reports will be submitted by 1 February of the year following site visits according to the schedule in Table 2. Reports will be provided to the appropriate regulatory agencies.

Remedial Action

If monitoring suggests that performance standards may not be met by Year 10, additional seeding, fertilizing and/or other planting approaches and will be considered in consultation with agency representatives.

TABLE 1: GOALS, OBJECTIVES, PERFORMANCE STANDARDS AND MONITORING METHODS

Goals	Establish diverse and productive aquatic, wetland and upland plant communities similar to those of the surrounding area, thereby improving the appearance of the site and improving its suitability for some species of fish and wildlife.
Objectives	**Terrestrial**: Short-term establishment of seeded grass and primary colonizers subject to competition and invasion by indigenous species over time. **Aquatic**: Establishment and persistence of transplanted species.
Performance Standard	**Terrestrial**: By year 10, 10% cover by live vascular plants comprised of at least 5 naturally colonizing species with at least 0.2% cover each.
Monitoring Methods	**Terrestrial Mine Site Areas**: Point intercept sampling along fixed transects. **Aquatic**: Repeat photography.

TABLE 2: PROPOSED SCHEDULE FOR APPLICATION OF REHABILITATION TREATMENTS, SITE MONITORING AND REPORTING

Year	Treatment & Monitoring	Reporting
Summer before mining activities	Pre-mining site characterization and vegetation classification.	Summary report to be used as baseline
First summer following completion of mining activities	Sample soil and have it tested for fertility and other features. Inspect site to determine extent of rehabilitation activities required. Collect photo records.	Internal activities report
Year 0	Apply fertilizer and seed, and install sprigs of aquatic species. Collect photo records.	Progress report
Year 2	Measure vegetation cover and species composition using point intercept sampling in seeded/fertilized areas, and compile a species list. Observe surface stability and sprig survival, and collect photo records.	Progress report
Year 6	Measure vegetation cover and species composition using point intercept sampling in seeded/fertilized areas, and compile a species list. Sample soil where revegetation success appears lacking. Observe surface stability and sprig survival, and collect photo records.	Progress report
Year 10	Measure vegetation cover and species composition using point intercept sampling in seeded/fertilized areas, and compile a species list. Observe surface stability and sprig survival, and collect photo records.	Final report

1. INTRODUCTION

This report presents the results of wetland delineations and wetland and waters mapping within the assessment area. The purpose of this work was to identify areas in the vicinity of the Point Thomson Project (Project) that are under the jurisdiction of Section 404 of the Clean Water Act (CWA) and Section 10 of the Rivers and Harbors Act (RHA), as interpreted by the Alaska District Army Corps of Engineers (USACE). A Section 10 permit is required for work in, or the placement of structures in, navigable Waters of the United States, defined as waters subject to the ebb and flow of the tide, and/or is presently used, or has been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A Section 404 permit is required for discharge of dredged or fill material into Waters of the United States and associated wetlands. Section 404 jurisdiction includes all "Waters of the United States," determined by connectivity to traditionally navigable waters as described in the federal guidance document *Clean Water Act Jurisdiction Following the U.S. Supreme Court's Decision in Rapanos v. United States & Carabell v. United States (December 2, 2008) (EPA/Corps, 2008)*.

This report and attached maps and data are provided for "preliminary" jurisdictional determination (PJD), to assist USACE in developing an approved jurisdictional determination (JD) of wetlands and waters within the assessment area. Additional information about the functional value and qualities of the wetlands can be found in HDR, Inc. (HDR's) *Draft Wetland Function Assessment* (HDR 2010), included as Appendix G in the Point Thomson Preliminary EIS document.

The assessment area referred to throughout this document encompasses the mapped areas in the Wetlands and Waters Map Atlas (Appendix A). For the purpose of this report, the entire assessment area has been evaluated for the presence of jurisdictional wetlands and waters. The assessment area includes all of the proposed Project infrastructure as well as surrounding areas that may be influenced by Project activities.

As described in the draft *Department of the Army, U. S. Army Corps of Engineers, Application for Permit (POA-2001-1082-M1)* 2011 (ExxonMobil, 2011) and supporting documentation, the Project includes gravel fill for roads, pads, and an airstrip; developing a gravel mine; barge offloading facilities to include mooring dolphins, bulkheads, and dredging/screeding; an emergency response boat launch; and pipelines (both gathering lines and the export pipeline) constructed on vertical support members (VSMs). All Project components are within the North Slope Borough of Alaska (see Figure 1). The Project is south of the Beaufort Sea, between the Staines and Shaviovik Rivers. Key Project components are located at (presented in Decimal Degrees):

- Central Pad: latitude 70.1713, longitude -146.2568;
- East Pad: latitude 70.1467, longitude -146.1084;
- West Pad: latitude 70.1806º N., longitude -146.4394;
- Alaska State C-1 Pad: latitude 70.1394, longitude -146.2441.

- Mine Site: latitude 70.1465, longitude -146.2528.
- Airstrip: latitude 70.1369, longitude -146.2849.
- Pipeline Start Point: (at Central Pad) latitude 70.171263, Longitude -146.264139;
- Pipeline Mid Point: latitude 70.158327, longitude -146.683645;
- Pipeline End Point (at Badami): latitude 70.150152, longitude -147.102663.

This work was performed by OASIS Environmental, Inc. (OASIS) for Exxon Mobil Corporation (ExxonMobil) under the direction of URS Corporation.

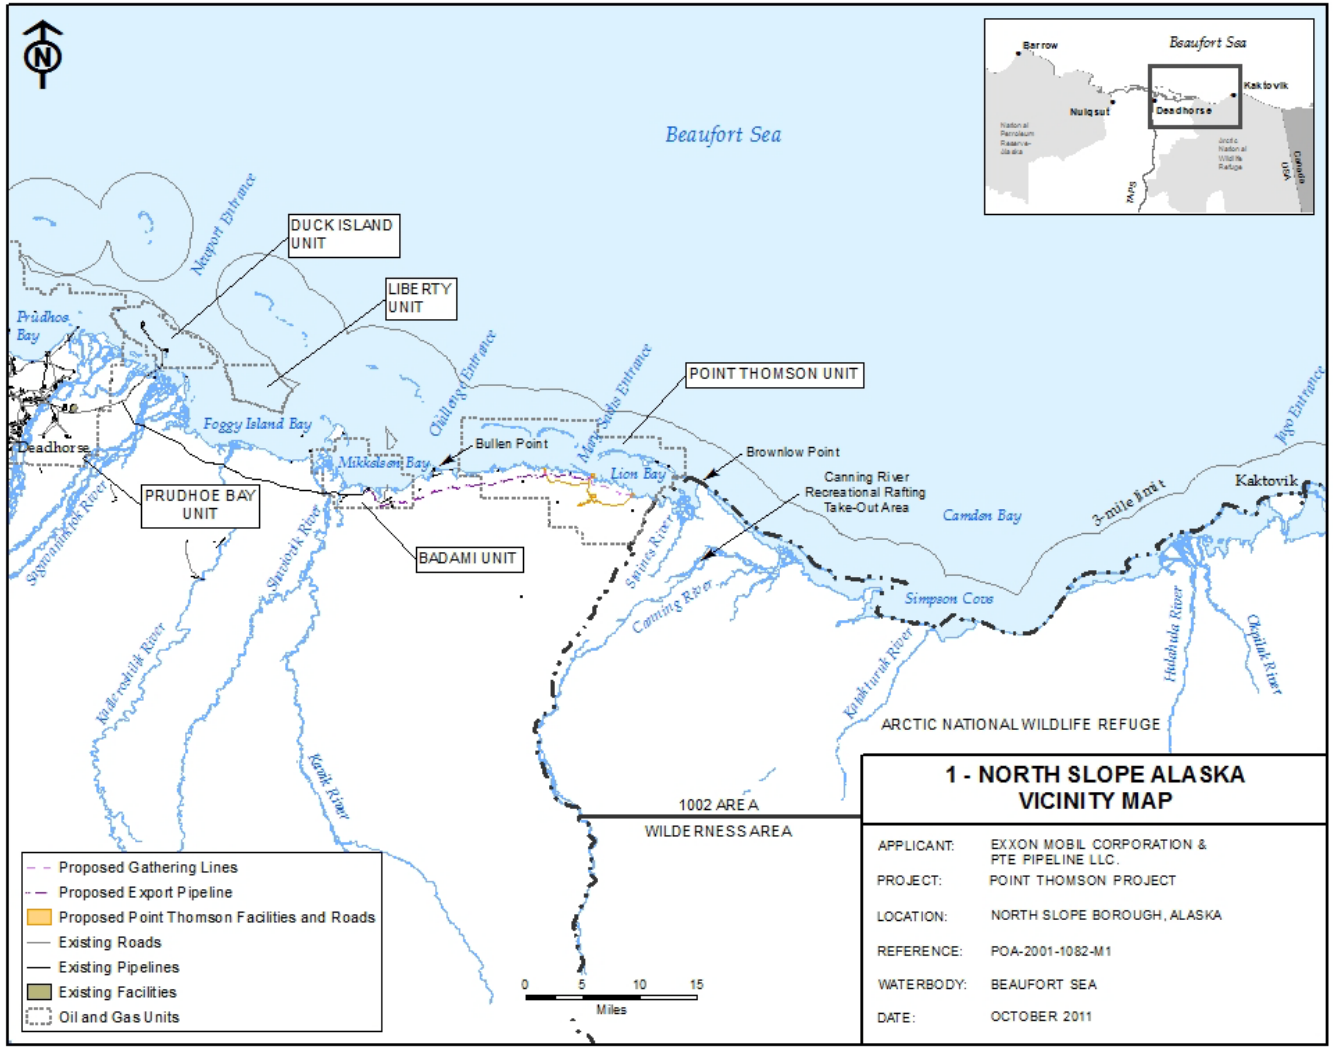

FIGURE 1. POINT THOMSON PROJECT AREA AND VICINITY MAP

- Page Intentionally Left Blank –

2. BACKGROUND INFORMATION

The assessment area is located in the Arctic Coastal Plain (ACP) physiographic province, a poorly drained, treeless coastal area that rises gradually from sea level to the northern foothills of the Brooks Range. Freeze-thaw cycles are the dominant force in shaping the landscape. The nearly level to gently rolling topography is underlain by thick permafrost, with an active layer of approximately one to four feet. This relatively impermeable permafrost acts as a shallow aquitard, creating a generally moist to wet environment with numerous ponds and lakes. Subtle changes in microtopography, affecting soil moisture regime, are closely connected to the distribution of vegetation communities.

Rivers and streams within the assessment area appear to have their headwaters either in the ACP, or further south in the Arctic Foothills (Exxon Mobil Corporation, 2009, 2011). Streams originating in the ACP tend to have lower velocities than those originating in the Arctic Foothills, and have one spring peak in their hydrograph, corresponding with spring breakup. Streams originating in the Arctic Foothills often have a second peak to their hydrograph, caused by fall rains in the Brooks Range and Arctic Foothills.

The assessment area spans approximately 22 miles, between the Badami Development to the west and the Staines River to the east (Figure 1 and Appendix A). Drilling and production facilities will be consolidated into three onshore gravel pads: Central, East, and West Pads. These three pads will be connected via gathering lines and in field roads. The Central Pad will also include the infrastructure to support remote operations and drilling. A gravel airstrip will be constructed for all-season transportation and emergency evacuations. To facilitate barge offloading, bulkheads and dolphins will be installed, and minor dredging/screeding will be conducted for the delivery of modules, equipment, and supplies by sea during the open water season. A gravel road between Point Thomson and other North Slope infrastructure is not planned. Winter ice roads will be used for construction and other activities and in support of operations, as needed. A gravel mine will be developed to support construction. VSMs will be installed to support infield gathering pipelines and an export pipeline that will convey product from the central processing facility to receiving infrastructure at the Badami Development. Additional Project details are found in the draft *Department of the Army, U. S. Army Corps of Engineers, Application for Permit (POA-2001-1082-M1)* 2011 (Exxon Mobil Corporation, 2011).

3. METHODS

3.1. Wetlands and Waters Mapping

Wetlands and waters within the entire assessment area were mapped using a combination of desktop and field techniques. Desktop analysis was used to complete the majority of the mapping effort and included an analysis of existing vegetation mapping, National Wetlands Inventory (NWI) mapping, aerial photographs, and surface hydrology data. The following data relevant to Project vegetation, soils, and hydrology were reviewed by OASIS:

- Detailed vegetation maps (Schick and Noel 1995; Noel and Funk 1999, 2001; OASIS 2009),
- 1:6000 natural color photography,
- 1:6000 topographic maps,
- Surface hydrology flow vectors (Alaska Clean Seas [ACS] 2010),
- U.S. Fish & Wildlife Service (USFWS) NWI mapping,
- Hydrology and hydrographic data compiled for the Environmental Report (Exxon Mobil Corporation, 2009), and
- Hydrology data from PND Engineers spring breakup study (PND 2009a).

Detailed vegetation mapping throughout the assessment area was the primary source of information for this effort (Schick and Noel 1995; Noel and Funk 1999, 2001; OASIS 2009). Vegetation throughout the assessment area was mapped to Level C of Walker's (1983) hierarchical vegetation classification, describing communities based on site moisture regime, dominant plant growth form, and physiognomy. This level of mapping relies on aerial photo interpretation with extensive ground reference data. Throughout the various mapping efforts, researchers visited over 500 locations within the mapping area to document species, dominant growth forms (e.g., sedge, dwarf shrub, forb, etc.), site moisture regimes (dry, moist, wet, or aquatic), and physiognomy (e.g., tundra, sand dunes, etc.). As defined by Walker's (1983) Level C classification, there are 24 vegetation types in the assessment area (Table 1, Appendix B; Photographs, Appendix F).

Detailed surface hydrology data (ACS 2010) were reviewed to determine connections between wetlands and waters within the assessment area. ACS (2010) interpreted surface flow vectors from 1:6,000 topographic maps in the Point Thomson Unit. These data indicate surface water flow connections between wetlands and waters likely during the early growing season when the water table is high and possible connections later in the growing season during precipitation events.

USFWS NWI maps were also reviewed for wetlands within the asssessment area. NWI maps, created from aerial photo interpretation with limited ground-truthing, are useful for identifying relatively large and obvious wetland areas for planning purposes. Due to the scale at which maps were created (typically 1:63,360) and the limited correlation with

conditions on the ground, some wetlands could be missed. The scale of the NWI maps is usually not sufficient to determine accurate wetland boundaries in the field, though it does provide a guide to the location of major wetland areas. NWI mapping was downloaded from the official NWI web site and reviewed for initial assessment and background information.

Limited wetland investigations occurred in August 2010, concurrent with collecting ground-reference data for an 11-mile portion of the vegetation map aerially interpretated by LGL Alaska Research Associates, Inc. (LGL) in 2001 (Noel and Funk 2001). While performing this work, OASIS also collected soils and hydrology data at seven locations in accordance with the currently accepted methods for wetland determination in Alaska, described in the *Alaska Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Alaska Region (Version 2.0; September 2007)* (USACE 2007a). While wetland data were not collected for every community throughout the assessment area, we believe that the limited data collection confirmed that communities within the assessment area were wetlands, and provided valuable information on the soils and hydrology of the assessment area that are not easily discernable from aerial photographs or desktop review.

The 'three parameter approach' employed in wetland determination requires the three essential characteristics of wetlands (hydrophytic vegetation, hydric soils, and wetland hydrology) be present to have a positive wetland determination.

3.1.1. **Wetland Vegetation**

Plants require special adaptations to survive the saturated or anaerobic conditions found in wetlands. The USFWS has published a list of plant species for Alaska (Reed 1988) that identifies the relative probability of these species occurring in wetlands. The list categorizes plant species as obligate (OBL), facultative wetland (FACW), facultative (FAC), facultative upland (FACU), upland (UPL), drawdown (DRA), not listed, or has not yet been assigned an indicator status. Definitions for each of these categories are as follows:

- OBL - Always found in wetlands under natural (not planted) conditions (frequency greater than 99%), but may persist in non-wetlands if planted there by man or in wetlands that have been drained, filled, or otherwise transformed into non-wetlands.
- FACW (facultative wetland) - Usually found in wetlands (66% - 99% frequency), but occasionally found in non-wetlands.
- FAC (facultative) - Sometimes found in wetlands (34% - 66% frequency), but also occurs in non-wetlands.
- FACU (facultative upland) - Seldom found in wetlands (1% - 33% frequency), and usually occurs in non-wetlands.
- UPL (upland) - Occurs in wetlands in another region, but not found (<1% frequency) in wetlands in the region specified (Alaska). If a species does not occur in wetlands in any region, it is not on the list.

- DRA (drawdown) - Typically associated with the drier stages of wetlands, such as mud flats, vernal pools, and playa lakes.

Plant species with an indicator status of OBL, FACW, or FAC are considered adapted for life in saturated or anaerobic soil conditions. Such species are referred to as hydrophytic vegetation, or hydrophytes.

The presence of hydrophytic vegetation is determined by either a Dominance Test or a Prevalence Index. The Dominance Test is generally a quick way to accurately characterize the vegetative community. However, communities with a large number of low cover species are more accurately characterized by the Prevalence Index, a weighted average of the wetland indicator status of all plant species in the community. Best professional judgment is used when determining which method to use to determine the presence or absence of hydrophytic vegetation.

Multiple previous mapping efforts have identified vegetation communities within the assessment area through a combination of aerial photo interpretation and ground reference data (Schick and Noel 1995; Noel and Funk 1999, 2001; OASIS 2009). Representative dominant species and their indicator status for each community within the assesment area are listed in Table 1 in Appendix B.

3.1.2. **Wetland Soils**

Hydric soils are indicative of wetlands. The National Resources Conservation Service has defined a hydric soil as "a soil that in its undrained condition is saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions that favor the growth and regeneration of hydrophytic vegetation. The criteria for hydric soils includes certain soil taxonomic groups that are poorly drained during the growing season, soils that are ponded during any part of the growing season, and soils that are frequently flooded for long or very long durations during the growing season.

Due to anaerobic conditions, hydric soils exhibit certain characteristics that can be observed in the field. These characteristics include the following:

- High organic content representing accumulation and slow decomposition in anaerobic conditions.
- Reduction of ferric iron (Fe^{3+}) to ferrous iron (Fe^{2+}) and consequent leaching from the soil profile, causing a greenish- or bluish-gray color (gley formation).
- Generation of hydrogen sulfide, noted by characteristic odor.
- Spots or blotches of different color interspersed with the matrix, or dominant color (mottling).
- Dark soil colors (low soil chroma).

Hydric soils were confirmed during field data collection efforts by OASIS in 2010 by digging test pits and identifying indicators for hydric soils (USACE 1987 and 2007). Additional soils information was obtained from literature and maps of the assessment area.

3.1.3. **Wetland Hydrology**

Water must be present in order for wetlands to exist; however, it does not need to be present throughout the entire year. Wetland hydrology is considered present when there is permanent or periodic water inundation or soil saturation for a significant period of time during the growing season. Indicators of wetland hydrology include areas of ponding or soil saturation, evidence of previous water inundation such as dry algae on bare soil, watermarks on soils or leaves, and drainage patterns. Where positive indicators are observed, it is assumed that wetland hydrology occurs for a significant period of the growing season. Field indicators of wetland hydrology included observations of inundation, saturation, and drainage patterns within wetlands. Test pits were dug to confirm the presence of wetland hydrology indicators below ground surface at limited wetland observation points.

Multiple previous mapping efforts have identified vegetation communities within the assessment area through a combination of aerial photo interpretation and ground reference data (Schick and Noel 1995; Noel and Funk 1999, 2001; OASIS 2009). The vegetation classification scheme (Walker 1983) includes a description of moisture regime (dry, moist, wet, or aquatic), a subjective determination of soil moisture at the end of the growing season. These moisture regimes were correlated with wetland hydrology indicators during limited data collected in 2010. Communities identified by Walker (1983) as dry typically had moist but not saturated soils at the end of the growing season, while communities identified by Walker (1983) as moist typically had saturated soils corresponding to the primary hydrology indicator (A3) saturation. Wet communities (Walker 1983) typically had standing water, meeting primary hydrology indicators (A1) surface water or (A2) high water table. Aquatic communities (Walker 1983) contained aquatic vegetation (e.g. *Arctophila fulva*, etc.) and were part of a persistent lake, pond, or stream/river, meeting primary hydrology indicator (A1), surface water.

3.2. Preliminary Jurisdictional Determination

To determine the potential jurisdictional determination categories appropriate for wetlands and waters within the assessment area, OASIS reviewed existing data including aerial photographs, topography, and detailed surface hydrology inferred from topographic maps and field data (ACS 2010, Worley Parsons 2010). This review was performed in consultation with federal guidance, including *Clean Water Act Jurisdiction Following the U.S. Supreme Court's Decision in Rapanos v. United States & Carabell v. United States (December 2, 2008)* (EPS/Corps 2008)*;* and *U.S. Army Corps of Engineers Jurisdictional Determination Form Instructional Guidebook and Approved Jurisdictional Determination Form (May 30. 2007)* (USACE 2007b). The JD categories for wetlands include:

- Wetlands Adjacent to Traditional Navigable Waters (TNWs)
- Wetlands Abutting Relatively Permanent Waters (RPWs) that flow directly or indirectly into TNWs

- Wetlands Adjacent (Not Abutting) to RPWs that flow directly or indirectly into TNWs*
- Wetlands Adjacent to non-RPWs that flow directly or indirectly into TNWs*
- Isolated Wetlands*

And the JD categories for waters include:

- TNW
- RPWs that flow directly or indirectly into TNWs
- Non-RPWs that flow directly or indirectly into TNWs*
- Impoundments of Jurisdictional Waters
- Isolated Waters*

* Designations require a significant nexus determination

TNWs were determined through review of the Alaska Department of Natural Resources (ADNR) Navigable Waters website mapping tool (ADNR 2010).

- Page Intentionally Left Blank -

4. FINDINGS

Wetlands within the assessment area are classified as Palustrine, Riverine, Lacustrine, or Estuarine by the USFWS (USFWS 2008 and Table 1 in Appendix B). Wetlands within the assessment area are surrounded by and connected to larger wetland systems. Riverine systems run south to north through the assessment area, and estuarine wetlands are located to the north of all assessment area wetlands.

4.1. Wetlands

The following provides a summary of wetland areas under the jurisdiction of Section 404 of the CWA. This determination was based on the location of wetlands relative to TNWs and RPWs and their hydrologic linkage to those water bodies.

4.1.1. **Determination and Mapping**

A total of 57,985 acres have been mapped in support of the Point Thomson Project, and are depicted in the attached Wetlands and Water Map Atlas (Appendix A). Wetland features are delineated as distinct vegetation communities following Walker's (1983) vegetation classification (Schick and Noel 1995; Noel and Funk 1999, 2001; OASIS 2009). Wetland delineation data sheets and photo documentation were completed for seven sample locations visited in 2010 and are included in Appendix C.

Vegetation communities include those associated with subtidal bays and inlets, rivers, streams, lakes and ponds, and palustrine scrub-shrub / emergent wetlands. The general vegetation community descriptions below were taken from Point Thomson Project Environmental Report (Exxon Mobil Corporation, 2009) and tabulated for the purposes of this report in Table 1 (Appendix B). For a detailed description of each vegetation community, please refer to the Schick and Noel (1995) and Noel and Funk (1999, 2001) reports.

> Water and wetlands are the predominant cover classes within the assessment area: 33.2 percent of the assessment area is covered by water, including subtidal bays and inlets, rivers, streams, lakes and ponds; 61.3 percent of the assessment area is covered by wetlands, including the palustrine scrub-shrub / emergent wetlands, Moist Sedge, Dwarf Shrub/Wet Sedge Tundra Complexes and Moist Sedge, Dwarf Shrub Tundra [see Wetlands and Water Map Atlas in Appendix A]; 5.3 percent of the assessment area is covered by dry complexes, bare peat and bare wet mud; and the remaing 0.2 percent of the assessment area is covered by gravel roads, pads and gravel washouts.
>
> Predominant vegetation types within the assessment area are Moist Sedge, Dwarf Shrub Tundra/Wet Sedge Tundra Complexes (38.3 percent of mapped vegetation) and Moist Sedge, Dwarf Shrub Tundra (20.3percent of mapped vegetation). Moist Sedge, Dwarf Shrub Tundra/Wet Sedge Tundra Complexes are typically found in high- and low-center polygon areas and in weakly

developed strangmoor (reticulated tundra). *Salix spp*., *Dryas integrifolia*, mesic *Carex spp.*, and a number of forbs dominate the polygon rims or high centers.

Salt marsh vegetation covers 2.7 percent of the assessment area. Dry Dwarf Shrub Lichen Tundra is also within the assessment area (2.7 percent), with the remaining vegetation types each accounting for less than 0.7 percent of the assessment area. Unvegetated river gravels, bare peat and wet mud account for approximately 1.9 percent of the assessment area. Human disturbances (gravel roads and pads and associated washouts) cover 0.2 percent of the assessment area and are confined to exploratory pads constructed in the Project area.

Most of the vegetation types in the assessment area are wetland plant communities. Exceptions are portions of the well-drained dwarf shrub, crustose and fruticose lichen communities associated with pingos and some high-center polygons, respectively, and partially vegetated sand dunes. Some riparian areas also are likely to be upland because of their gravel substrate and infrequent inundation. Tundra disturbed by gravel fill also may be converted to upland, depending on the thickness of the fill; placing a sufficient thickness of gravel may cause an area to lose hydric soil, hydrophytic vegetation, and/or wetland hydrology, all of which are required for an area to be a wetland (Exxon Mobil Corporation, 2009, pg 3-74 to 3-75).

Non-wetland communities make up a very small portion of the overall vegetation survey area – excluding previously filled areas, less than 1%. For the purposes of making a PJD for the assessment area, these non-wetland areas were essentially ignored and the entire assessment area is considered wetland or open water.

4.1.2. **Potential Jurisdictional Status**

All wetlands identified within the assessment area are believed to fall under potential CWA jurisdiction based on either observation or inference of hydrologic connections linking these wetlands with TNWs. A Preliminary JD Form has been prepared for the entire assessment area as supporting documentation for this report (Appendix D).

All wetlands within the assessment area are considered to fall into one of the following JD categories:

- Wetlands adjacent to TNWs – These wetlands have a direct hydrologic connection with adjacent TNWs through continuous soil saturation, or shallow groundwater flow due to their close proximity to and location upgradient of a TNW (Beaufort Sea).
- Wetlands abutting RPWs that flow directly or indirectly into TNWs – These wetlands have a direct hydrologic connection with abutting RPWs through seasonal flooding, continuous soil saturation, or shallow groundwater flow; the RPWs eventually flow into a TNW (Beaufort Sea).

Detailed surface hydrology data were reviewed to determine connections between assessment area wetlands and TNWs (Beaufort Sea). ACS technicians manually interpreted surface flow vectors through review of detailed North Slope topography,

identifying surface water flow paths between wetlands and waters. ACS surface hydrology data for the assessment area is represented by surface water flow vectors on the Wetlands and Water Atlas Maps (Appendix A). Data were evaluated beyond the assessment area to determine connections to TNWs.

In addition to potential surficial connections, wetlands within the ACP are also expected to have a hydrologic connection to TNWs through adjacent soil saturation. This condition can extend into adjacent wetlands for extended distances before encountering an RPW or TNW, and can link seemingly "isolated" wetlands to streams and rivers that flow into large TNWs, and eventually the Beaufort Sea.

Wetlands in the following categories were not identified in the assessment area:

- Wetlands adjacent (not abutting) RPWs that flow directly or indirectly into TNWs*
- Wetlands adjacent (not abutting) to non-RPWs that flow directly or indirectly into TNWs*
- Isolated wetlands*

* These designations require a significant nexus determination.

Because these categories are not asserted, a technical determination of a significant nexus is not presented.

4.2. Waters

Surface water bodies in the assessment area that are under the jurisdiction of Section 404 of the CWA include streams, lakes and ponds, and the coastal waters of the Beaufort Sea. Additionally, the coastal waters of the Beaufort Sea are under the jurisdiction of Section 10 of the RHA. A general description of each surface water type is provided below.

4.2.1. Determinations and Mapping

Surface water features cover 33.2 percent of the assessment area and include subtidal bays and inlets, rivers, streams, lakes and ponds. These surface water features were mapped within the assessment area, and are depicted in the Wetlands and Waters Map Atlas (Appendix A). Appendix E provides tabulated data that summarizes the location of streams and lakes within the assessment area, and includes known hydrology data.

4.2.1.1. Streams

The following general description for streams and rivers identified within the assessment area was taken from Exxon Mobil Corporation, 2009. Tabulated data for each stream located within one mile of the proposed Project pipeline and road alignments is provided in Appendix E. For additional details and data collected for streams and rivers in the assessment area, please refer to PND (2009) and Worley Parsons (2010).

> The runoff characteristics of watersheds within the assessment area are influenced by climate, physiography, surficial geology, and permafrost. A number of rivers and streams cross the proposed pipeline and road alignments

associated with the Project [(Wetlands and Waters Map Atlas, Appendix A)]. All of these rivers and streams appear to have their headwaters in either the Arctic Foothills or the ACP physiographic provinces, with most headwaters in the ACP. Because there are some general characteristics of the rivers and streams that can be inferred from the physiographic provinces through which the rivers and streams flow, a short description of the physiographic provinces and the general characteristics of river reaches within those provinces is presented.

The ACP begins a few feet above the shoreline of the Beaufort Sea and extends to the Arctic Foothills, which can be as high as 600 feet above mean sea level (Hydrocon 1982). Stream reaches within the ACP generally have lower gradients and velocities than those found in the Foothills or the Brooks Range provinces. Streams originating on the ACP are often the first to freeze in the fall, and are often dry or nearly dry at freeze-up. These streams are usually the last to break up in the spring, with break-up timing significantly influenced by local weather patterns. Because the ice in these streams tends to freeze to the streambed, and because thaw bulbs probably do not exist below most of these streams, they tend to have few ice floes during break-up.

The Arctic Foothills province is between the ACP and the Brooks Range provinces. The Arctic Foothills generally consist of low, rolling hills with intermediate plateaus and tundra plains. Stream reaches within the Arctic Foothills are generally steeper than those in the ACP and generally have higher velocities. Streams originating in the Arctic Foothills tend to break up earlier and freeze up later than those in the ACP.

The rivers and streams crossed by the proposed pipelines and road routes associated with the assessment area have drainage areas that vary in size from less than 1 square mile to more than 90 square miles (Michael Baker Jr., Inc. 1998; PND 2009a). Several of the watersheds lack clearly defined boundaries or drainage channels, whereas others contain well-defined stream channels. The median size of the drainage basins crossed by the proposed pipelines and road routes is probably less than 6 square miles. Most of these streams are small and often consist of a tundra-lined swale. Some of the streams are beaded, which means that they consist of a series of small pools interconnected by short, narrow stream segments. Some of the streams have incised channels with gravel beds. The streams that are not simply tundra swales usually have a gravel streambed, and gravel is often found in the bottom of the small pools in the beaded streams. Hydrologic data were collected for some of the rivers and streams in 1983 (Dames & Moore), 1998 (Michael Baker Jr., Inc.), 2003a (URS), 2009 (PND) and 2010 (Worley Parsons), and are summarized in Tables 1 and 2 provided in Appendix E.

The major rivers that border the assessment area are: the Canning and Staines rivers to the east, and the Shaviovik River to the West. The Staines River is a tributary of the Canning River. The Canning River has its headwaters in the

Brooks Range province and has a drainage area of approximately 2,200 square miles (ExxonMobil 2003). The Shaviovik River also has its headwaters in the Brook Range and has a drainage area of approximately 1,600 square miles (Exxon Mobil Corporation, 2009, pg 3-15 to 3-16).

4.2.1.2. Lakes and Ponds

The coastal plain in the assessment area has numerous lakes and ponds, the vast majority of which are less than 6 feet deep and freeze to the bottom or very near the bottom in most years (Exxon Mobil Corporation, 2009). The following general description of the lakes and ponds located within the assessment area is an excerpt from Exxon Mobil Corporation, (2009, pg. 3-12):

> Wind-oriented thaw lakes dominate the landscape in the coastal zone. The thaw-lake basins originate in areas of restricted drainage, where shallow ponding results in a warmer surface temperature that causes the underlying ground ice to thaw, resulting in subsidence. Most of the ponds and lakes are relatively shallow.
>
> The thaw lakes are considered dynamic and impermanent, and often go through a cycle of development, expansion, drainage, and revegetation. Ice tends to be concentrated in the top few meters of the permafrost (Sellman et al. 1975). Of several types of ice that occur in the near-surface sediments, segregated ice and ice wedges represent as much as 85 percent of the ground by volume, with the former contributing a much greater amount (75 percent) than the ice wedges (Brown 1967). Natural and human-induced differential thawing of this near-surface ice generally results in uneven lowering of the ground surface, which may lead to ponding of water or preferential erosion, or both (Rawlinson 1993).

Due to the sheer number and temporal nature of the lakes and ponds located within the assessment area, there is limited lake/pond specific data available.

4.2.1.3. Coastal Waters

The northern portion of the assessment area extends into the coastal waterways of Lion Bay and the Beaufort Sea. Detailed information associated with the physical and biological characteristics of Lion Bay and the Beaufort Sea is provided in (Exxon Mobil Corporation, 2009). For the purposes of this report, a brief general description of Lion Bay, the Beaufort Sea and the interconnecting estuaries is provided below (Exxon Mobil Corporation, 2009, pg. 3-54, 3-58 and 3-59):

> Lion Bay, formerly known as Lion Lagoon, is located directly offshore of Point Thomson and about 46 miles (74 kilometers) east of Prudhoe Bay. Flaxman Island and a chain of barrier islands, known as the Maguire Islands (including Challenge, Alaska, Duchess, and Northstar islands), form the bay. The Beaufort Sea lies seaward of these islands (Wetlands and Waters Map Atlas, Appendix A). Lion Bay is approximately 3–4 miles (5–6 kilometers) long, with water depths typically 5–13 feet (1.5–4 meters). Passes or gaps between the barrier islands

serve to connect the bay waters with the Beaufort Sea and thus waves, storm surges, and other regional oceanographic processes influence the bay waters.

The Canning and Staines rivers provide freshwater input to the Beaufort Sea in the vicinity of Point Thomson. The river outflow into coastal waters provides low-saline waters along the coast. From its headwaters to the coast, the Canning River is about 117 miles (188 kilometers) long and has a drainage area of about 2,256 square miles (5,843 square kilometers). The river has a braided, meandering channel, with low banks and broad floodplains consisting of gravel terraces. The discharge of the Canning River averages 1,125 cfs (31.86 cubic meters per second [m^3/sec]) (AEIDC 1974). Large coastal rivers such as the Canning show no measurable discharge from January–early May (MMS 1996). By contrast, the Staines River has an annual average flow of 14 cfs (0.40 m^3/sec) (AEIDC 1974). This river is 21 miles (34 kilometers) long and has a drainage area of about 28 square miles (73 km^2). The nearshore salinity is most affected by runoff from the Canning River and other streams during the summer/fall (open water) period.

4.2.2. **Potential Jurisdictional Status**

All surface waters identified within the assessment area are potentially jurisdictional under Section 404 of the CWA, classified as

- TNW, or
- RPWs that flow directly or indirectly into TNWs.

The Beaufort Sea is also jurisdictional under Section 10 of the RHA, classified as:

- TNW (water subject to the ebb and flow of the tide).

As noted above, detailed surface hydrology data were reviewed to determine connections between assessment area surface water features and TNWs (Beaufort Sea). ACS surface hydrology data for the assessment area are represented by surface water flow vectors on the Wetlands and Water Atlas Maps (Appendix A). Data were evaluated beyond the assessment area to determine connections to TNWs.

The Beaufort Sea is the only TNW identified within the assessment area. Based on the detailed surface hydrology vector maps developed by ACS (2010) and supporting hydrologic and vegetation mapping data provided in Exxon Mobil Corporation, (2009), lakes, streams, and rivers within the assessment area are believed to be RPWs that flow directly into a TNW (Beaufort Sea) or have direct hydrologic connections to other RPWs that flow into TNWs. Where there is no obvious surficial connection, waters are connected indirectly to other RPWs through continuous soil saturation in abutting wetlands. As discussed for wetlands in the assessment area, the continuous permafrost of the ACP provides hydrological connections unique to Alaska. Supporting documentation for the preliminary jurisdictional status of the surface water bodies within the assesment area is provided in the Preliminary JD Form provided in Appendix D.

Wetlands and Waters Atlas Maps

- Page Intentionally Left Blank -

Ia — Ia. Water (ponds, lakes, rivers, streams, saltwater).Estuarine Subtidal (E1UBL), Riverine, Permanently, and Tidally Influenced(R1UBV, R2UBH), and Lacustrine (L1UBH, L2UBH) and Palustrine Water Bodies (PUBH).

IIb — IIb. Aquatic Graminoid Tundra (emergent vegetation).Lacustrine (L2EM2H) and Palustrine (PEM1H) Permanently Flooded Emergent Marshes.

IId — IId. Water/Tundra Complex (inter-connected ponds with emergentvegetation).Lacustrine (L2UB/EM2H) and Palustrine (PUB/EM2H) Complexes of Open Water and Emergent Vegetation.

IIIa — IIIa. Wet Sedge TundraPalustrine (PEM1B, PEM1E) Saturated Wet Sedge Meadows. Wet SedgeMeadows may be Permanently or Semi-Permanently Flooded (PEM1H,PEM1F).

IIIb — IIIb. Wet Graminoid Tundra (wet saline tundra, salt marsh).Estuarine Emergent Intertidal (E2EM1N, E2EM1P).

IIIc — IIIc. Wet Sedge Tundra/Water Complex (inter-connected ponds with noemergent vegetation).Lacustrine (L2EM2/UBH) and Palustrine (PEM1/UBH) Complexes of Emergent Vegetation and Open Water.

IIId — IIId. Wet Sedge/Moist Sedge, Dwarf Shrub Tundra Complex(wet patterned-ground complex).Palustrine Scrub Shrub Complexes, Wet Sedge Meadows (PSS/EM1B) and Saturated Wet Sedge Meadows (PEM1B, PEM1E). Wet Sedge Meadows may be Permanently or Semi-Permanently Flooded (PEM1H, PEM1F).

IIIe — IIIe. Wet Graminoid, Dwarf Shrub Tundra/Barren Complex(frost-scar tundra complex).Palustrine Scrub Shrub Complexes, Wet Sedge Meadows (PSS/EM1B)and Saturated Wet Sedge Meadows (PEM1B, PEM1E). Wet Sedge Meadows may be Permanently or Semi-Permanently Flooded (PEM1H, PEM1F).

IVa — IVa. Moist Sedge, Dwarf Shrub/Wet Graminoid Tundra Complex(moist patterned-ground complex).Palustrine Scrub Shrub Complex, Wet Sedge Meadows (PSS/EM1B)and Saturated Wet Sedge Meadows (PEM1E). Wet Sedge Meadows may be Permanently or Semi-Permanently Flooded (PEM1H, PEM1F).

Va — Va. Moist Sedge, Dwarf Shrub Tundra.Palustrine Saturated Shrub Emergent Wetlands (PSS/EM1B).

Vb — Vb. Moist Tussock Sedge, Dwarf Shrub Tundra.Palustrine Saturated Emergent and Scrub Shrub Wetlands (PEM/SS1B).

Vc — Vc. Dry Dwarf Shrub, Crustose Lichen Tundra (Dryas tundra, pingos).Uplands.

Vd — Vd. Dry Dwarf Shrub, Fruticose Lichen Tundra (dry acidic tundra).Upland and Palustrine Emergent Moist/Wet Sedge Meadows. (PEM1B,PEM1E) Wet Sedge Meadows may be Permanently or Semi-Permanently Flooded (PEM1H, PEM1F).

Ve — Ve. Moist Graminoid, Dwarf Shrub Tundra/Barren Complex(frost-scar tundra complex).Palustrine Saturated Scrub Shrub Emergent Wetlands (PSS/EM1B).

IXb — IXb. Dry Barren/Dwarf Shrub, Forb Grass Complex (forb-rich river bars)Upland and Palustrine, Temporarily Flooded Riparian Open Shrub(PSS/EM1A).

IXc — IXc. Dry Barren/Forb Complex (river bars in active channels)Palustrine Partially Vegetated Emergent Persistent Well Drained(PEM1/USD).

IXe — IXe. Dry Barren/Grass Complex.Upland.

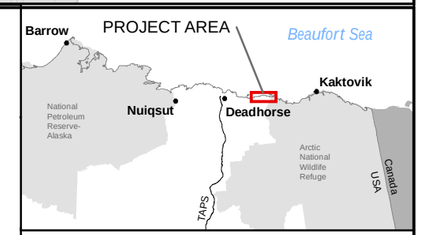
IXf — IXf. Dry Barren/Dwarf Shrub, Grass Complex (sand dune steppe).Upland.

IXh — IXh. Wet Barren/Wet Sedge Tundra Complex (barren/saline tundra complex, saltmarsh).Estuarine Intertidal, Regularly Flooded Mud Flats (E2USN, E2USP) with Emergent Intertidal (E2EM1P).

IXi — IXi. Dry Barren/Forb, Graminoid Complex (saline coastal barrens).Unknown (Original Vegetation Salt-Killed); Possibly was Saturated Scrub Shrub Emergent Wetlands (PSS/EM1B).

Xa — Xa. River Gravels.Riverine, Seasonally Flooded Areas (R2USC, R3USC).

Xc — Xc. Barren Gravel Outcrops.Upland/Unknown.



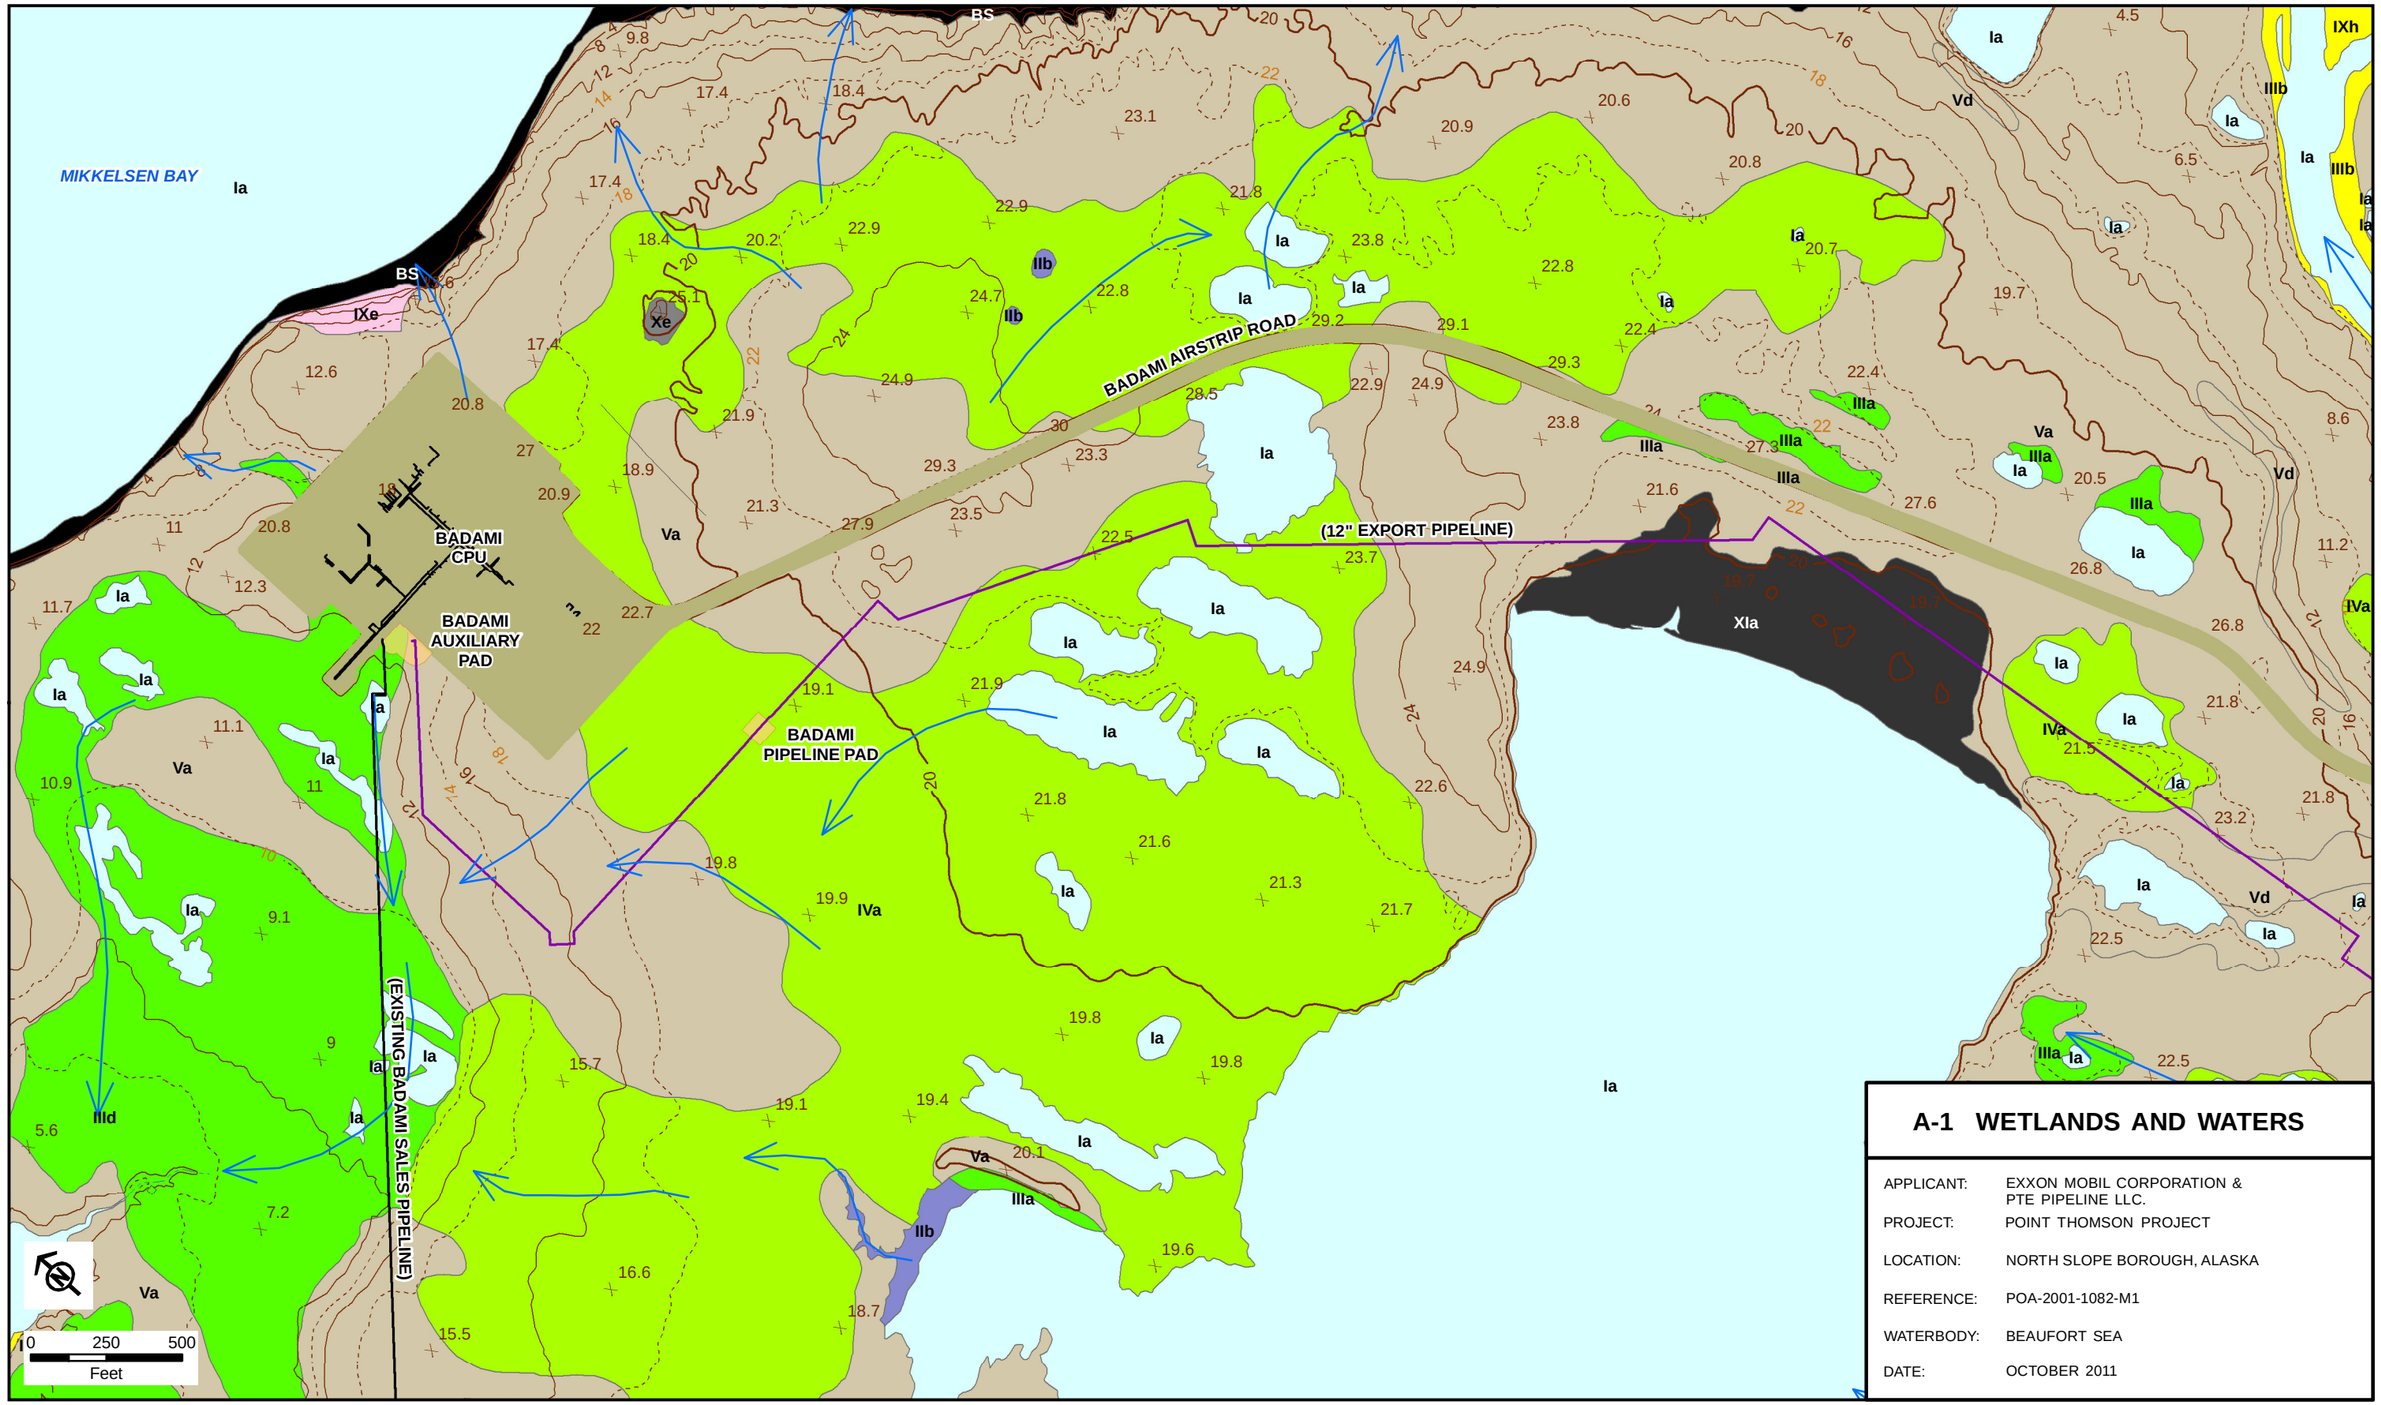
Xe — Xe. Gravel Roads and Pads.Upland/Unkown.

XIa — XIa. Wet Mud (drained lakes and ponds).Exposed Lacustrine (L2USD) and Palustrine Peat (PUSD) and Sediments.

XIc — XIc. Bare Peat.Exposed Lacustrine (L2USD) and Palustrine Peat (PUSD) and Sediments.

BS — BS. Barren Sand/Gravel

Surface Flow Hydrology (provided by Alaska Clean Seas)



MAP SOURCE INFORMATION:
Between Point Thomson Area & Badami Area Vegetation interpreted from color infrared aerial photography dated July 19, 1997 and July 2, 1994 supplemented by natural color aerial photography dated July 1, 1993. Point Thomson Area Vegetation interpreted from color infrared aerial photography dated July 19, 1997 supplemented by natural color aerial photography dated July 1, 1993, and from field observations, 1998. Section 13 of T9N R23E was filled in through hybrid image classification by OASIS Environmental, Inc. August 30, 2009. Badami Area Vegetation interpreted from enlarged natural color aerial photography dated July 1, 1993 and supplemented by field observations.

Appendix B

Vegetation Community Table and Cowardin Classification Key

- Page Intentionally Left Blank -

Table 1. Vegetation and Wetland Types that Occur in the Point Thomson Assessment Area, Alaska

Vegetation Type	Level C Types	Wetland Type[1]	Description/Dominant Plant Species[2]	Total Area	
				Acres	Percent
Water	Bays, lagoons, inlets, subtidal rivers (Ia)	Estuarine subtidal (E1UBL).	Low energy brackish water.	19219.9	33.2
	Rivers and streams (Ia)	Riverine, permanently and tidally influenced (R1UBV, R2UBH, R3UBH).	Includes tidally influenced rivers upstream from ocean derived salinity.		
	Lakes/Ponds (Ia)	Lacustrine (L1UBH, L2UBH) and Palustrine (PUBH) waterbodies.	Includes wind orientated thaw lakes and ponds.		
			Water Total	*19220.0*	*33.2*
Salt Marsh	Wet Graminoid Tundra (IIIb)	Estuarine emergent intertidal (E2EM1N, E2EM1P).	Regularly and irregularly flooded salt marsh.	614.7	1.0
	Wet Barren/Wet Graminoid Tundra Complex (IXh)	Estuarine intertidal, regularly flooded mud flats (E2USN, E2USP) with emergent intertidal (E2EM1P).	Regularly and irregularly flooded salt marsh with large patches of unvegetated, exposed intertidal sediments. Species include *Puccinellia phryganodes* (OBL), *Carex subspathacea* (OBL), *C. ursine* (FACW), *Dupontia fisheri* (FACW), *Stellaria humifusa* (OBL), and *Cochlearia officinalis* (FAC).	296.5	0.5
	Dry Barren/Forb Graminoid Complex (IXi)	Unknown (original vegetation salt-killed); possibly was saturated scrub shrub emergent wetlands (PSS/EM1B).	Coastal vegetation Intermittently flooded by saltwater resulting in death of original vegetation. New colonizers include *Puccinellia* spp., *Carex ursine* (FACW), *Stellaria humifusa* (OBL), and *Cochlearia officinalis* (FAC).	663.2	1.2
			Water and Salt Marsh Total	*1575.3*	*2.7*
Aquatic Graminoid Tundra	Aquatic Graminoid Tundra (IIb)	Lacustrine (L2EM2H) and Palustrine (PEM1H) permanently flooded emergent marshes.	*Arctophila fulva* (OBL) occurs in deep water areas, whereas *Carex aquatilis* (OBL), *Eriophorum angustifolium* (OBL) and *E. scheuchzeri* (OBL) occur in shallow water areas.	297.7	0.5

Vegetation Type	Level C Types	Wetland Type[1]	Description/Dominant Plant Species[2]	Total Area	
				Acres	Percent
Water/Tundra Complex	Water/Tundra Complex (IId)	Lacustrine (L2UB/EM2H) and Palustrine (PUB/EM2H, PUB/EM1H) complexes of open water and emergent vegetation.	Dominated by open water interspersed with patches of emergent Aquatic Graminoid Tundra (see above). Moist microsites are dominated by species found in Wet Sedge Tundra and Moist Sedge, Dwarf Shrub Tundra (see above).	206.7	0.3
Wet Sedge Tundra	Wet Sedge Tundra (IIIa)	Palustrine PEM1B, PEM1E saturated wet sedge meadows. Some wet sedge meadows also may be permanently or semi-permanently flooded (PEM1H, PEM1F).	*Carex aquatilis* (OBL), *C. rotundata* (OBL), *C. saxatilis* (FACW), and *Eriophorum* spp. *Dupontia fisheri* (FACW) is frequently codominant along the coast.	1479.9	2.5
Wet Sedge Tundra/Water Complex	Wet Sedge Tundra/Water Complex (IIIc)	Lacustrine (L2EM2/UBH) and Palustrine (PEM1/UBH) complexes of emergent vegetation and open water.	Similar to above except that vegetation is dominant and emergent vegetation is not typically found in the open water areas. Wet Sedge Tundra is the dominant community type (see above).	688.3	1.2
Moist Sedge, Dwarf Shrub Tundra/ Wet Sedge Tundra Complex	Wet Sedge/Moist Sedge, Dwarf Shrub Tundra Complex (IIId)	Complexes of palustrine scrub shrub, wet sedge meadows (PSS/EM1B) and saturated wet sedge meadows (PEM1B, PEM1E). Some wet sedge meadows also may be permanently or semi-permanently flooded (PEM1H, PEM1F).	Patterned ground dominated by Moist Sedge, Dwarf Shrub Tundra (see above) on low-center polygon rims and high-center polygon centers. Wet Sedge Tundra (see above) occurs in the basins of the low-center polygons and in the troughs of the high-center polygons. Frost-scarred barren areas also are associated with this complex.	9544.8	16.6
	Wet Graminoid, Dwarf Shrub Tundra/Barren Complex (IIIe)	see above	see above	300.0	0.5
	Moist Sedge, Dwarf Shrub/Wet Graminoid Tundra Complex (IVa)	see above	see above	9691.5	16.7
			Moist Sedge, Dwarf Shrub Tundra/ Wet Sedge Tundra Complex Total	*22208.9*	*38.3*
Moist Sedge, Dwarf Shrub Tundra	Moist Sedge, Dwarf Shrub Tundra (Va)	Palustrine saturated scrub shrub emergent wetlands (PSS/EM1B).	High-center polygons comprising *Salix pulchra, S. arctica* (FAC), *S. reticulata* (FAC), *Dryas integrifolia* (FACU), *Carex misandra* (FAC), *C. bigelowii* (FAC), and *C. atrofusca* (FACW). Frost-scarred barren areas also are associated with this type.	9868.2	17.0
	Moist Graminoid, Dwarf Shrub Tundra/Barren Complex (Ve)	see above	see above	1840.3	3.3
			Moist Sedge, Dwarf Shrub Tundra Total	*11708.5*	*20.3*

Vegetation Type	Level C Types	Wetland Type[1]	Description/Dominant Plant Species[2]	Total Area	
				Acres	Percent
Moist Tussock Sedge, Dwarf Shrub Tundra	Moist Tussock Sedge, Dwarf Shrub Tundra (Vb)	Palustrine saturated emergent and scrub shrub wetlands (PEM/SS1B).	Dominated by tussock cottongrass (*Eriophorum vaginatum* (FACW) with other sedges including *E. angustifolium* (OBL), *Carex bigelowii* (FAC), and *C. misandra* (FAC). Common shrubs include *Dryas integrifolia* (FACU), *Salix reticulata* (FAC), and *S. planifolia* sp. *Pulchra*). Dominant forbs include *Cassiope tetragona* (FACU), and *Polygonum viviparum* (FAC). These communities occur between lake-basins and on the sides of pingos, in better-drained soils.	0.0	0.0
Dry Dwarf Shrub, Crustose Lichens	Dry Dwarf Shrub, Crustose Lichens (Vc)	Upland	Well drained sites (commonly pingos) comprising *Dryas integrifolia* (FACU), *Salix rotundifolia* (NI), *S. phlebophylla* (FACU), *Carex rupestris* (FACU), and a diversity of legumes and forbs. Exposed mineral soil covered with crustose lichens.	727.1	1.2
Dry Dwarf Shrub, Fruticose Lichens	Dry Dwarf Shrub, Fruticose Lichens (Vd)	Upland and palustrine emergent moist/wet sedge meadows (PEM1B, PEM1E). Some wet sedge meadows also may be permanently or semi-permanently flooded (PEM1H, PEM1F).	Well-drained high-center polygons with narrow, well-developed polygon troughs. Vegetation on the high centers is similar to Dry Dwarf Shrub (see above), with the addition of *Cassiope tetragona* (FACU), *Vaccinium vitis-idaea* (FAC) and mesic forbs (e.g. *Saxifraga punctata* (FAC) and *Pyrola grandiflora* (FAC)). Exposed peaty soil covered with fruticose lichens.	891.8	1.5
Dry Barren/Dwarf Shrub, Forb Grass Complex	Dry Barren/Dwarf Shrub, Forb Grass Complex (IXb)	Upland and palustrine, temporarily flooded riparian open shrub (PSS/EM1A)	Diverse assemblage of shrubs, grasses, and forbs on a moderately well-drained gravel substrate. Species include *Salix rotundifolia* (NI), *S. phlebophylla* (FACU), *S. reticulata* (FAC), *Dryas integrifolia* (FACU), *Deschampsia caespitosa* (FAC), *Alopecurus alpines* (FACW), *Poa glauca*, *Astragalus alpines* (FAC), *Epilobium latifolium* (FAC), and *Artemisia arctica*.	371.3	0.6
Dry Barren/ Forb Complex	Dry Barren/ Forb Complex (IXc)	Palustrine partially vegetated emergent persistent well drained (PEM1/USD)	Seasonally flooded, well drained areas on river floodplains that are partially vegetated with *Epilobium latifolium* (FAC), *Artemisia arctica*, and *Wilhelmsia physodes* (FAC).	56.1	<0.1
Dry Barren/Grass Complex	Dry Barren/Grass Complex (IXe)	Upland	Coastal sand dunes partially vegetated with *Elymus arenarius*.	6.7	<0.1
Dry Barren/Dwarf Shrub, Grass Complex	Dry Barren/Dwarf Shrub, Grass Complex (IXf)	Upland	Partially vegetated sand dunes. Species include *Salix ovalifolia* (FAC), *Artemisia borealis*, *A. glomerata*, *Deschampsia caespitosa* (FAC), and *Trisetum spicatum* (FAC).	4.7	<0.1

Vegetation Type	Level C Types	Wetland Type[1]	Description/Dominant Plant Species[2]	Total Area	
				Acres	Percent
River Gravels	River Gravels (Xa)	Riverine, seasonally flooded areas (R2USC, R3USC).	Bare gravels	432.4	0.7
Bare Peat, Wet Mud	Wet Mud (XIa)	Exposed Lacustrine (L2USD) and Palustrine (PUSD) peat and sediments.	Drained lake basins.	655.2	1.1
	Bare Peat (XIc)	see above	see above	28.8	<0.1
			Dry Complexes, Bare Peat, Wet Mud Total	*3173.2*	*5.3*
Gravel Roads and Pads (and washouts) (Xe, Xc)	Barren Gravel Outcrops (Xc)	Upland/Unknown	Wetland status of gravel washouts on tundra depends on thickness of gravel fill.	4.8	<0.1
	Gravel Roads and Pads (Xe)	see above	see above	94.6	0.1
			Gravel Roads and Pads (and washouts) (Xe, Xc) Total	*99.4*	*0.2*

[1]Study area was not specifically classified and mapped into wetland types, but rather vegetation types (Walker 1983) were reclassified into wetland types, based on USFWS National Wetland Inventory (NWI) nomenclature (Cowardin et al 1979).

WETLAND DETERMINATION DATA FORM – Alaska Region

Project/Site: Pt. Thomson Borough/City: North Slope Borough Sampling Date: 8/13/2010

Applicant/Owner: Exxon-Mobil Sampling Point: 1

Investigator(s): K.Webb & M. Lee Landform (hillside, terrace, hummocks, etc.): estuarine fringe

Local relief (concave, convex, none): None Slope (%): 0%

Subregion: _____ Lat: 70°10' 49.15" N Long: 146° 36' 09.46" W Datum: WGS 1984

Soil Map Unit Name: _____ NWI classification: E2EM1N

Are climatic / hydrologic conditions on the site typical for this time of year? Yes X No _____ (If no, explain in Remarks.)

Are Vegetation _____, Soil _____, or Hydrology _____ significantly disturbed? N Are "Normal Circumstances" present? Yes X No _____

Are Vegetation _____, Soil _____, or Hydrology _____ naturally problematic? N (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No _____	**Is the Sampled Area within a Wetland?** Yes X No _____
Hydric Soil Present?	Yes X	No _____	
Wetland Hydrology Present?	Yes X	No _____	

Remarks: Walker (1983) vegetation type: wet graminoid tundra (IIIb)

VEGETATION – Use scientific names of plants. List all species in the plot.

WETLAND DETERMINATION DATA FORM – Alaska Region

Project/Site: Point Thomson Borough/City: North Slope Borough Sampling Date: 8/14/2010

Applicant/Owner: Exxon Mobil Sampling Point: 6

Investigator(s): K. Webb & M. Lee Landform (hillside, terrace, hummocks, etc.):

Local relief (concave, convex, none): None Slope (%): 0-3%

Subregion: Northern Lat: 70° 10' 05.169" N Long: 146° 35" 10.030" W Datum: WGS84

Soil Map Unit Name: NWI classification:

Are climatic / hydrologic conditions on the site typical for this time of year? Yes Y No (If no, explain in Remarks.)

Are Vegetation _____, Soil _____, or Hydrology _____ significantly disturbed? N Are "Normal Circumstances" present? Yes X No _____

Are Vegetation _____, Soil _____, or Hydrology _____ naturally problematic? N (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X No _____	**Is the Sampled Area within a Wetland?** Yes X No _____
Hydric Soil Present?	Yes X No _____	
Wetland Hydrology Present?	Yes X No _____	

Remarks: Walker (1983) vegetation type: wet sedge / moist sedge, dwarf shrub tundra complex (IIId)

VEGETATION – Use scientific names of plants. List all species in the plot.

Preliminary Jurisdictional Determination Form

- Page Intentionally Left Blank -

APPROVED JURISDICTIONAL DETERMINATION FORM
U.S. Army Corps of Engineers

This form should be completed by following the instructions provided in Section IV of the JD Form Instructional Guidebook.

SECTION I: BACKGROUND INFORMATION

A. REPORT COMPLETION DATE FOR APPROVED JURISDICTIONAL DETERMINATION (JD):

B. DISTRICT OFFICE, FILE NAME, AND NUMBER:

C. PROJECT LOCATION AND BACKGROUND INFORMATION: The project area spans approximately 22 miles, between the Badami Development to the west and the Staines River to the east. Refer to the Point Thomson Project Preliminary Jurisdictional Determination Report (OASIS 2011).

State: Alaska County/parish/borough: North Slope Borough City: n/a
Center coordinates of site (lat/long in degree decimal format): Lat. ° **Pick List**, Long. ° **Pick List**.
Universal Transverse Mercator:
Name of nearest waterbody: Beaufort Sea
Name of nearest Traditional Navigable Water (TNW) into which the aquatic resource flows: Beaufort Sea
Name of watershed or Hydrologic Unit Code (HUC): Mikkelson Bay (HUC: 19060403) and Canning River (HUC: 19060501)

☒ Check if map/diagram of review area and/or potential jurisdictional areas is/are available upon request.
☐ Check if other sites (e.g., offsite mitigation sites, disposal sites, etc…) are associated with this action and are recorded on a different JD form.

D. REVIEW PERFORMED FOR SITE EVALUATION (CHECK ALL THAT APPLY):

☐ Office (Desk) Determination. Date:
☐ Field Determination. Date(s):

SECTION II: SUMMARY OF FINDINGS

A. RHA SECTION 10 DETERMINATION OF JURISDICTION.

There **Are** *"navigable waters of the U.S."* within Rivers and Harbors Act (RHA) jurisdiction (as defined by 33 CFR part 329) in the review area. [*Required*]

☒ Waters subject to the ebb and flow of the tide.
☒ Waters are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce.
Explain: The Beaufort Sea is used as a means to transport supplies and materials in support of oil and gas development on the North Slope. It is anticipated that supplies and materials for the Point Thomson Project will be barged to the site via Lion Bay. Fresh water from jurisdictional water sources will also be used in support of the Project.

B. CWA SECTION 404 DETERMINATION OF JURISDICTION.

There **Are** "*waters of the U.S.*" within Clean Water Act (CWA) jurisdiction (as defined by 33 CFR part 328) in the review area. [*Required*]

1. **Waters of the U.S.**
   a. **Indicate presence of waters of U.S. in review area (check all that apply):** [1]
      ☒ TNWs, including territorial seas
      ☒ Wetlands adjacent to TNWs
      ☒ Relatively permanent waters[2] (RPWs) that flow directly or indirectly into TNWs
      ☒ Non-RPWs that flow directly or indirectly into TNWs
      ☒ Wetlands directly abutting RPWs that flow directly or indirectly into TNWs
      ☐ Wetlands adjacent to but not directly abutting RPWs that flow directly or indirectly into TNWs
      ☒ Wetlands adjacent to non-RPWs that flow directly or indirectly into TNWs
      ☐ Impoundments of jurisdictional waters
      ☐ Isolated (interstate or intrastate) waters, including isolated wetlands

   b. **Identify (estimate) size of waters of the U.S. in the review area:**
      Non-wetland waters: linear feet: width (ft) and/or acres.
      Wetlands: 57,985 acres.

   c. **Limits (boundaries) of jurisdiction** based on: **Pick List**
      Elevation of established OHWM (if known): Unknown. Refer to Point Thomson Project Preliminary Jurisdictional Determination Report (OASIS 2011).

2. **Non-regulated waters/wetlands (check if applicable):**[3]

[1] Boxes checked below shall be supported by completing the appropriate sections in Section III below.
[2] For purposes of this form, an RPW is defined as a tributary that is not a TNW and that typically flows year-round or has continuous flow at least "seasonally" (e.g., typically 3 months).
[3] Supporting documentation is presented in Section III.F.

☒ Potentially jurisdictional waters and/or wetlands were assessed within the review area and determined to be not jurisdictional. Explain: .

SECTION III: CWA ANALYSIS

A. TNWs AND WETLANDS ADJACENT TO TNWs

The agencies will assert jurisdiction over TNWs and wetlands adjacent to TNWs. If the aquatic resource is a TNW, complete Section III.A.1 and Section III.D.1. only; if the aquatic resource is a wetland adjacent to a TNW, complete Sections III.A.1 and 2 and Section III.D.1.; otherwise, see Section III.B below.

1. TNW
Identify TNW: **Beaufort Sea**.

Summarize rationale supporting determination: As determined by ADNR navigable waters public access unit.

2. Wetland adjacent to TNW
Summarize rationale supporting conclusion that wetland is "adjacent": Wetlands are contiguous throughout the assessment area. These wetlands have a direct hydrologic connection with adjacent TNWs through continuous soil saturation, or shallow groundwater flow due to their close proximity to and location upgradient of a TNW (Beaufort Sea)..

B. CHARACTERISTICS OF TRIBUTARY (THAT IS NOT A TNW) AND ITS ADJACENT WETLANDS (IF ANY):

This section summarizes information regarding characteristics of the tributary and its adjacent wetlands, if any, and it helps determine whether or not the standards for jurisdiction established under *Rapanos* have been met.

The agencies will assert jurisdiction over non-navigable tributaries of TNWs where the tributaries are "relatively permanent waters" (RPWs), i.e. tributaries that typically flow year-round or have continuous flow at least seasonally (e.g., typically 3 months). A wetland that directly abuts an RPW is also jurisdictional. If the aquatic resource is not a TNW, but has year-round (perennial) flow, skip to Section III.D.2. If the aquatic resource is a wetland directly abutting a tributary with perennial flow, skip to Section III.D.4.

A wetland that is adjacent to but that does not directly abut an RPW requires a significant nexus evaluation. Corps districts and EPA regions will include in the record any available information that documents the existence of a significant nexus between a relatively permanent tributary that is not perennial (and its adjacent wetlands if any) and a traditional navigable water, even though a significant nexus finding is not required as a matter of law.

If the waterbody[4] is not an RPW, or a wetland directly abutting an RPW, a JD will require additional data to determine if the waterbody has a significant nexus with a TNW. If the tributary has adjacent wetlands, the significant nexus evaluation must consider the tributary in combination with all of its adjacent wetlands. This significant nexus evaluation that combines, for analytical purposes, the tributary and all of its adjacent wetlands is used whether the review area identified in the JD request is the tributary, or its adjacent wetlands, or both. If the JD covers a tributary with adjacent wetlands, complete Section III.B.1 for the tributary, Section III.B.2 for any onsite wetlands, and Section III.B.3 for all wetlands adjacent to that tributary, both onsite and offsite. The determination whether a significant nexus exists is determined in Section III.C below.

1. Characteristics of non-TNWs that flow directly or indirectly into TNW

(i) General Area Conditions:
Watershed size: **Pick List**
Drainage area: **Pick List**
Average annual rainfall: inches
Average annual snowfall: inches

(ii) Physical Characteristics:
(a) Relationship with TNW:
☐ Tributary flows directly into TNW.
☐ Tributary flows through **Pick List** tributaries before entering TNW.

Project waters are **Pick List** river miles from TNW.
Project waters are **Pick List** river miles from RPW.
Project waters are **Pick List** aerial (straight) miles from TNW.
Project waters are **Pick List** aerial (straight) miles from RPW.
Project waters cross or serve as state boundaries. Explain: .

[4] Note that the Instructional Guidebook contains additional information regarding swales, ditches, washes, and erosional features generally and in the arid West.

Identify flow route to TNW[5]: .
Tributary stream order, if known: .

(b) General Tributary Characteristics (check all that apply):
Tributary is: ☐ Natural
☐ Artificial (man-made). Explain: .
☐ Manipulated (man-altered). Explain: .

Tributary properties with respect to top of bank (estimate):
Average width: feet
Average depth: feet
Average side slopes: **Pick List.**

Primary tributary substrate composition (check all that apply):
☐ Silts ☐ Sands ☐ Concrete
☐ Cobbles ☐ Gravel ☐ Muck
☐ Bedrock ☐ Vegetation. Type/% cover:
☐ Other. Explain: .

Tributary condition/stability [e.g., highly eroding, sloughing banks]. Explain: .
Presence of run/riffle/pool complexes. Explain: .
Tributary geometry: **Pick List**
Tributary gradient (approximate average slope): %

(c) Flow:
Tributary provides for: **Pick List**
Estimate average number of flow events in review area/year: **Pick List**
Describe flow regime: .
Other information on duration and volume: .

Surface flow is: **Pick List.** Characteristics: .

Subsurface flow: **Pick List**. Explain findings: .
☐ Dye (or other) test performed: .

Tributary has (check all that apply):
☐ Bed and banks
☐ OHWM[6] (check all indicators that apply):
☐ clear, natural line impressed on the bank ☐ the presence of litter and debris
☐ changes in the character of soil ☐ destruction of terrestrial vegetation
☐ shelving ☐ the presence of wrack line
☐ vegetation matted down, bent, or absent ☐ sediment sorting
☐ leaf litter disturbed or washed away ☐ scour
☐ sediment deposition ☐ multiple observed or predicted flow events
☐ water staining ☐ abrupt change in plant community
☐ other (list):
☐ Discontinuous OHWM.[7] Explain: .

If factors other than the OHWM were used to determine lateral extent of CWA jurisdiction (check all that apply):
☐ High Tide Line indicated by: ☐ Mean High Water Mark indicated by:
☐ oil or scum line along shore objects ☐ survey to available datum;
☐ fine shell or debris deposits (foreshore) ☐ physical markings;
☐ physical markings/characteristics ☐ vegetation lines/changes in vegetation types.
☐ tidal gauges
☐ other (list):

(iii) Chemical Characteristics:
Characterize tributary (e.g., water color is clear, discolored, oily film; water quality; general watershed characteristics, etc.).
Explain: .
Identify specific pollutants, if known: .

[5] Flow route can be described by identifying, e.g., tributary a, which flows through the review area, to flow into tributary b, which then flows into TNW.
[6] A natural or man-made discontinuity in the OHWM does not necessarily sever jurisdiction (e.g., where the stream temporarily flows underground, or where the OHWM has been removed by development or agricultural practices). Where there is a break in the OHWM that is unrelated to the waterbody's flow regime (e.g., flow over a rock outcrop or through a culvert), the agencies will look for indicators of flow above and below the break.
[7] Ibid.

(iv) Biological Characteristics. Channel supports (check all that apply):

- ☐ Riparian corridor. Characteristics (type, average width): .
- ☐ Wetland fringe. Characteristics: .
- ☐ Habitat for:
  - ☐ Federally Listed species. Explain findings: .
  - ☐ Fish/spawn areas. Explain findings: .
  - ☐ Other environmentally-sensitive species. Explain findings: .
  - ☐ Aquatic/wildlife diversity. Explain findings: .

2. Characteristics of wetlands adjacent to non-TNW that flow directly or indirectly into TNW

(i) Physical Characteristics:

(a) General Wetland Characteristics:

Properties:

Wetland size: 57,985 acres

Wetland type. Explain:Vegetation and wetland communities include those associated with subtidal bays and inlets, rivers, streams, lakes and ponds, and palustrine scrub-shrub / emergent wetlands. .

Wetland quality. Explain: Wetland function and value assessment by HDR is in progress.

Project wetlands cross or serve as state boundaries. Explain: n/a.

(b) General Flow Relationship with Non-TNW:

Flow is: **Pick List**. Explain: Due to different waterbodies types within the assessment area, all flow types apply. Refer to Point Thompson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).

Surface flow is**: Pick List**

Characteristics: Due to different waterbodies types within the assessment area, all flow types apply. Refer to Point Thompson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).

Subsurface flow: **Yes**. Explain findings: In addition to potential surficial connections, wetlands within the ACP are also expected to have a hydrologic connection to TNWs and non-TNWs through adjacent soil saturation. This condition can extend into adjacent wetlands for extended distances before encountering an RPW or TNW, and can link seemingly "isolated" wetlands to streams and rivers that flow into large TNWs, and eventually the Beaufort Sea. .

- ☐ Dye (or other) test performed: .

(c) Wetland Adjacency Determination with Non-TNW:

- ☒ Directly abutting
- ☐ Not directly abutting
  - ☐ Discrete wetland hydrologic connection. Explain: .
  - ☐ Ecological connection. Explain: .
  - ☐ Separated by berm/barrier. Explain: .

(d) Proximity (Relationship) to TNW

Project wetlands are **1 (or less)** river miles from TNW.

Project waters are **1 (or less)** aerial (straight) miles from TNW.

Flow is from: **Wetland to navigable waters.**

Estimate approximate location of wetland as within the **2-year or less** floodplain.

(ii) Chemical Characteristics:

Characterize wetland system (e.g., water color is clear, brown, oil film on surface; water quality; general watershed characteristics; etc.). Explain: Water quality varies, but is predominatley brown.

Identify specific pollutants, if known: Unknown.

(iii) Biological Characteristics. Wetland supports (check all that apply):

☒ Riparian buffer. Characteristics (type, average width): Refer to Point Thompson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).

☒ Vegetation type/percent cover. Explain: Refer to Point Thompson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).

☒ Habitat for:

- ☒ Federally Listed species. Explain findings: Refer to Point Thomson Project Environmental Report, November 2009.
- ☒ Fish/spawn areas. Explain findings: Refer to Point Thomson Project Environmental Report, November 2009.
- ☒ Other environmentally-sensitive species. Explain findings: Refer to Point Thomson Project Environmental Report, November 2009.
- ☒ Aquatic/wildlife diversity. Explain findings: Refer to Point Thomson Project Environmental Report, November 2009.

3. Characteristics of all wetlands adjacent to the tributary (if any)

All wetland(s) being considered in the cumulative analysis: **1**

Approximately (57,985) acres in total are being considered in the cumulative analysis.

For each wetland, specify the following:

Directly abuts? (Y/N)	Size (in acres)	Directly abuts? (Y/N)	Size (in acres)
Y	57,985		

Summarize overall biological, chemical and physical functions being performed: Refer to Wetland function and value assessment by HDR (in progress).

C. SIGNIFICANT NEXUS DETERMINATION

A significant nexus analysis will assess the flow characteristics and functions of the tributary itself and the functions performed by any wetlands adjacent to the tributary to determine if they significantly affect the chemical, physical, and biological integrity of a TNW. For each of the following situations, a significant nexus exists if the tributary, in combination with all of its adjacent wetlands, has more than a speculative or insubstantial effect on the chemical, physical and/or biological integrity of a TNW. Considerations when evaluating significant nexus include, but are not limited to the volume, duration, and frequency of the flow of water in the tributary and its proximity to a TNW, and the functions performed by the tributary and all its adjacent wetlands. It is not appropriate to determine significant nexus based solely on any specific threshold of distance (e.g. between a tributary and its adjacent wetland or between a tributary and the TNW). Similarly, the fact an adjacent wetland lies within or outside of a floodplain is not solely determinative of significant nexus.

Draw connections between the features documented and the effects on the TNW, as identified in the *Rapanos* Guidance and discussed in the Instructional Guidebook. Factors to consider include, for example:

- Does the tributary, in combination with its adjacent wetlands (if any), have the capacity to carry pollutants or flood waters to TNWs, or to reduce the amount of pollutants or flood waters reaching a TNW?
- Does the tributary, in combination with its adjacent wetlands (if any), provide habitat and lifecycle support functions for fish and other species, such as feeding, nesting, spawning, or rearing young for species that are present in the TNW?
- Does the tributary, in combination with its adjacent wetlands (if any), have the capacity to transfer nutrients and organic carbon that support downstream foodwebs?
- Does the tributary, in combination with its adjacent wetlands (if any), have other relationships to the physical, chemical, or biological integrity of the TNW?

Note: the above list of considerations is not inclusive and other functions observed or known to occur should be documented below:

1. **Significant nexus findings for non-RPW that has no adjacent wetlands and flows directly or indirectly into TNWs.** Explain findings of presence or absence of significant nexus below, based on the tributary itself, then go to Section III.D:n/a.

2. **Significant nexus findings for non-RPW and its adjacent wetlands, where the non-RPW flows directly or indirectly into TNWs.** Explain findings of presence or absence of significant nexus below, based on the tributary in combination with all of its adjacent wetlands, then go to Section III.D: Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).

3. **Significant nexus findings for wetlands adjacent to an RPW but that do not directly abut the RPW.** Explain findings of presence or absence of significant nexus below, based on the tributary in combination with all of its adjacent wetlands, then go to Section III.D: n/a.

D. DETERMINATIONS OF JURISDICTIONAL FINDINGS. THE SUBJECT WATERS/WETLANDS ARE (CHECK ALL THAT APPLY):

1. **TNWs and Adjacent Wetlands.** Check all that apply and provide size estimates in review area:
   ☒ TNWs: linear feet width (ft), Or, Refer to Point Thomson Project Wetlands and Waters Technical Report and Maps (OASIS 2010) acres.
   ☒ Wetlands adjacent to TNWs: Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011) acres.

2. **RPWs that flow directly or indirectly into TNWs.**
   ☒ Tributaries of TNWs where tributaries typically flow year-round are jurisdictional. Provide data and rationale indicating that tributary is perennial: Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011) and Point Thomson Development 2009 Spring Break-Up Hydrology Report (PND, 2009). Addition surface hydrology data is under analysis by PND and will be available in late 2010.

☒ Tributaries of TNW where tributaries have continuous flow "seasonally" (e.g., typically three months each year) are jurisdictional. Data supporting this conclusion is provided at Section III.B. Provide rationale indicating that tributary flows seasonally: Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011) and Point Thomson Development 2009 Spring Break-Up Hydrology Report (PND, 2009). Addition surface hydrology data is under analysis by PND and will be available in late 2010.

Provide estimates for jurisdictional waters in the review area (check all that apply):
☒ Tributary waters: **unknown** linear feet **unknown**width (ft).
☐ Other non-wetland waters: acres.
Identify type(s) of waters: .

3. Non-RPWs[8] that flow directly or indirectly into TNWs.

☒ Waterbody that is not a TNW or an RPW, but flows directly or indirectly into a TNW, and it has a significant nexus with a TNW is jurisdictional. Data supporting this conclusion is provided at Section III.C.

Provide estimates for jurisdictional waters within the review area (check all that apply):
☒ Tributary waters: **unknown** linear feet **unknown** width (ft).
☐ Other non-wetland waters: acres.
Identify type(s) of waters: **.**

4. Wetlands directly abutting an RPW that flow directly or indirectly into TNWs.

☒ Wetlands directly abut RPW and thus are jurisdictional as adjacent wetlands.

☒ Wetlands directly abutting an RPW where tributaries typically flow year-round. Provide data and rationale indicating that tributary is perennial in Section III.D.2, above. Provide rationale indicating that wetland is directly abutting an RPW: **Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).**

☒ Wetlands directly abutting an RPW where tributaries typically flow "seasonally." Provide data indicating that tributary is seasonal in Section III.B and rationale in Section III.D.2, above. Provide rationale indicating that wetland is directly abutting an RPW: Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).

Provide acreage estimates for jurisdictional wetlands in the review area: **57,985** acres.

5. Wetlands adjacent to but not directly abutting an RPW that flow directly or indirectly into TNWs.

☐ Wetlands that do not directly abut an RPW, but when considered in combination with the tributary to which they are adjacent and with similarly situated adjacent wetlands, have a significant nexus with a TNW are jurisidictional. Data supporting this conclusion is provided at Section III.C.

Provide acreage estimates for jurisdictional wetlands in the review area: acres.

6. Wetlands adjacent to non-RPWs that flow directly or indirectly into TNWs.

☒ Wetlands adjacent to such waters, and have when considered in combination with the tributary to which they are adjacent and with similarly situated adjacent wetlands, have a significant nexus with a TNW are jurisdictional. Data supporting this conclusion is provided at Section III.C.

Provide estimates for jurisdictional wetlands in the review area: **57,985**acres.

7. Impoundments of jurisdictional waters.[9]

As a general rule, the impoundment of a jurisdictional tributary remains jurisdictional.
☐ Demonstrate that impoundment was created from "waters of the U.S.," or
☐ Demonstrate that water meets the criteria for one of the categories presented above (1-6), or
☐ Demonstrate that water is isolated with a nexus to commerce (see E below).

E. ISOLATED [INTERSTATE OR INTRA-STATE] WATERS, INCLUDING ISOLATED WETLANDS, THE USE, DEGRADATION OR DESTRUCTION OF WHICH COULD AFFECT INTERSTATE COMMERCE, INCLUDING ANY SUCH WATERS (CHECK ALL THAT APPLY):[10]

[8] See Footnote # 3.
[9] To complete the analysis refer to the key in Section III.D.6 of the Instructional Guidebook.

☐ which are or could be used by interstate or foreign travelers for recreational or other purposes.
☐ from which fish or shellfish are or could be taken and sold in interstate or foreign commerce.
☐ which are or could be used for industrial purposes by industries in interstate commerce.
☐ Interstate isolated waters. Explain: .
☐ Other factors. Explain: .

Identify water body and summarize rationale supporting determination: .

Provide estimates for jurisdictional waters in the review area (check all that apply):
☐ Tributary waters: linear feet width (ft).
☐ Other non-wetland waters: acres.
Identify type(s) of waters: .
☐ Wetlands: acres.

F. NON-JURISDICTIONAL WATERS, INCLUDING WETLANDS (CHECK ALL THAT APPLY):
☐ If potential wetlands were assessed within the review area, these areas did not meet the criteria in the 1987 Corps of Engineers Wetland Delineation Manual and/or appropriate Regional Supplements.
☐ Review area included isolated waters with no substantial nexus to interstate (or foreign) commerce.
☐ Prior to the Jan 2001 Supreme Court decision in "*SWANCC*," the review area would have been regulated based solely on the "Migratory Bird Rule" (MBR).
☐ Waters do not meet the "Significant Nexus" standard, where such a finding is required for jurisdiction. Explain: .
☐ Other: (explain, if not covered above): .

Provide acreage estimates for non-jurisdictional waters in the review area, where the sole potential basis of jurisdiction is the MBR factors (i.e., presence of migratory birds, presence of endangered species, use of water for irrigated agriculture), using best professional judgment (check all that apply):
☐ Non-wetland waters (i.e., rivers, streams): linear feet width (ft).
☐ Lakes/ponds: acres.
☐ Other non-wetland waters: acres. List type of aquatic resource: .
☐ Wetlands: acres.

Provide acreage estimates for non-jurisdictional waters in the review area that do not meet the "Significant Nexus" standard, where such a finding is required for jurisdiction (check all that apply):
☐ Non-wetland waters (i.e., rivers, streams): linear feet, width (ft).
☐ Lakes/ponds: acres.
☐ Other non-wetland waters: acres. List type of aquatic resource: .
☐ Wetlands: acres.

SECTION IV: DATA SOURCES.

A. SUPPORTING DATA. Data reviewed for JD (check all that apply - checked items shall be included in case file and, where checked and requested, appropriately reference sources below):
☒ Maps, plans, plots or plat submitted by or on behalf of the applicant/consultant: .
☒ Data sheets prepared/submitted by or on behalf of the applicant/consultant.
☐ Office concurs with data sheets/delineation report.
☐ Office does not concur with data sheets/delineation report.
☐ Data sheets prepared by the Corps: .
☐ Corps navigable waters' study: .
☒ U.S. Geological Survey Hydrologic Atlas: .
☒ USGS NHD data.
☒ USGS 8 and 12 digit HUC maps.
☒ U.S. Geological Survey map(s). Cite scale & quad name: 1:63,360 - Beechy Point A-1, Flaxman Island A-5 and A-6.
☐ USDA Natural Resources Conservation Service Soil Survey. Citation: .
☒ National wetlands inventory map(s). Cite name: Alaska Wetlands Mapper Dataset (National Wetlands Inventory).
☐ State/Local wetland inventory map(s): .
☐ FEMA/FIRM maps: .
☐ 100-year Floodplain Elevation is: (National Geodectic Vertical Datum of 1929)

---

[10] Prior to asserting or declining CWA jurisdiction based solely on this category, Corps Districts will elevate the action to Corps and EPA HQ for review consistent with the process described in the Corps/EPA *Memorandum Regarding CWA Act Jurisdiction Following Rapanos.*

☒ Photographs: ☒ Aerial (Name & Date): Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).
or ☐ Other (Name & Date): .
☐ Previous determination(s). File no. and date of response letter: .
☐ Applicable/supporting case law: .
☒ Applicable/supporting scientific literature: Refer to Point Thomson Project Preliminary Jurisdictional Determination Report and Maps (OASIS 2011).
☐ Other information (please specify): .

B. ADDITIONAL COMMENTS TO SUPPORT JD: .

Appendix E

Streams and Lakes Surface Hydrology Data

- Page Intentionally Left Blank -

Table 2 (ExxonMobil 2009): Summary of Available Stream Width and Bankfull Data Collected Within One Mile of the Proposed Pipeline or Road Alignments

Stream Name	Site Location[1,2]	Approximate Drainage Area (sq.mi.)	Stream Width (ft)				Bankfull		References

Notes:

[1] Based on a visual inspection of the maps contained in the referenced documents, the pipeline alignment monitored by URS (2003a) appears to be approximately the same pipeline alignment monitored by PND (2009a).

[2] Based on a visual inspection of the maps contained in the referenced documents, the pipeline alignment monitored by Michael Baker Jr., Inc. (1998) is usually within one-half mile of the pipeline alignment monitored by PND (2009a). It is often closer to the coast.

[3] The ordinary high water line was generally taken to be the break between the upland vegetation and little or no vegetation. Often there was a cut bank present at this location.

[4] Typically the top of the low flow bank was taken to be the top of the cut bank. However, in some of the streams there was a feature farther from the gravel bottom that appeared to represent a low bank.

[5] The floodplain break on either side of the channel is defined as the point at which the nearly level floodplain begins to slope more steeply toward the channel, usually with a slope equal to or greater than 5 horizontal to 1 vertical. were made.

cfs = cubic feet per second

fps = feet per second

ft = feet

sq. mi. = square mile

URS. 2009b. *Point Thomson Environmental Report* . Prepared for Exxon Mobile Corporation. November 2009.

Notes:

Based on a visual inspection of the maps contained in the Dames & Moore (1983) and Hydrocon (1982) documents, the Dames & Moore monitoring sites (1983) on East Badami Creek and "L" Creek appear to be within 1 mile of the 2009 proposed pipeline alignment (PND 2009a).

[1] Based on a visual inspection of the maps contained in the referenced documents, the pipeline alignment monitored by URS (2003a) appears to be approximately the same pipeline alignment monitored by PND (2009a).

[2] Based on a visual inspection of the maps contained in the referenced documents, the pipeline alignment monitored by Michael Baker Jr., Inc. (1998) is usually within one-half mile of the pipeline alignment monitored by PND (2009a). It is often closer to the coast.

[3] Measurement was made at the spring peak stage.

[4] Estimate of spring peak discharge based on extrapolation from other measurements.

[5] The exact date of the measurement was not provided, but the date must have been between May 27th and June 13th, the period during which field measurements were made.

[6] Water surface width greatly affected by downstream snow blockage.

cfs = cubic feet per second

fps = feet per second

ft = feet

sq. mi. = square mile

Inupiaq and Scientific Names

POINT THOMSON PROJECT EIS

Iñupiaq and Scientific Names for Places, Plants, Mammals, Birds and Fish

U.S. Army Engineer District
Alaska Regulatory Division CEPOA-RD
Post Office Box 6898
JBER, AK 99506-0898

January 2010

This appendix has been included to aid readers in identifying place names and plant and animal names based on the Iñupiaq language and scientific names. The information is arranged in tables for place names (Table 1), plants (Table 2), mammals (Table 3), birds (Table 4), fish (Table 5) and invertebrates (Table 6). The tables are based on place names, plants, and animals on the North Slope that are identified in the EIS. In some cases there are no Iñupiaq names for places, plants, and animals; these are labeled as not applicable (NA).

Table 1: Place Names

Place Name	Iñupiaq Name
Admiralty Inlet	Tasiq
Aichilik River	Aichilik
Alaskan Island	NA
Anaktuvuk Pass	Anaqtuuvak
Arctic Foothills	Iiguaåruich
Atigaru Point	Atigruk nuvuk
Badami	NA
Badami River Flake Scatter	NA
Barter Island	Qaaktuåvik
Beechey Point	nuvuåaq
Bering Sea	Bering Sea-mi Taåiuq
Berlin wall	NA
Brownlow Cemetery	Agliåuaårug-mi Iøuvåich
Brownlow Southern Grave	Agliåuaåruum Ualiñåani Iøuviq
Brownlow Point	Agliåuaåruk
Brownlow Prehistoric Surface Artifacts	Agliåuaåugmi alåaaniqsat Qaaÿani
Beaufort Sea coast	Taåium Siñaa Beaufort Sea-mi
Bernard Spit	NA
Bullen Point	NA
Camden Bay	NA
Canning River	Kuugruaq
Cape Halkett	Isuk
Chandler River	Maqpik
Chirikov Basin	NA
Chukchi Sea	Chukchi Taåiuq
Collison Point	NA
Colville River	Kuukpik
Cottle Island	NA
Cross Island	Napaqsralik
Demarcation Point	Pattaqtuq
Duchess Island	NA
East Flaxman Island	Sirraq
First Fish Hole	Alluaqqaaq

Table 1: Place Names	
Place Name	Iñupiaq Name
Fish Creek	Iqalliqpik
Flaxman Bay	Sirraåmi tasiq
Foggy Island Bay	NA
Franklin Bluffs	Franklin Ikpigruaqpaÿich
Gallagher Flint Station	NA
Griffin Point	Uqsruqtalik
Harrison Bay	Harrison Tasiq
Howe Island	Howe Qikiqtaq
Hulahula River	Hulahula kuuk
Imaignauraq	Imaiåñauraq
Itkillik River	Itqiliq kuuk
Itkillipaat	Itqillimpaana
Jacob's ladder	Jacob-gum mayuåautiÿa
Jago River	Jago kuuk
Judy Creek	NA
Kadleroshilik River	Qaliåusiøik
Kanginniivik	Qanåiññiivik
Kangich	Qanåich
Karparuk River	Kuukpaaåruk
Kangakut River	Kaÿiqqat
Kaktovik	Qaaktuåvik
Kavik River	Qavvik kuuk
Kogru River	Kuugruaq
Kongakut River	Kaÿiqqat kuuk
Kuparuk oil field	Kuukpaaårugmi niuqtuåviq
Kuparuk Hills	Kuukpaaårugmi qimiqqat
Kuparuk Pingo	Kuukpaaåruk Piÿu
Leffingwell Camp	NA
Lion Bay	NA
Lion Lagoon	NA
Lisburne Site	NA
Mackenzie River	NA
Maguire Islands	NA
Manning Point	NA
McClure Islands	Makluri
Mikkelson Bay	NA
Narwhal Island	Aåvisuaq qikiqtaq
Nechelik Channel	NA

Table 1: Place Names	
Place Name	Iñupiaq Name
Nigliq Channel	Niåliq Channel
Noatak River	Nutaaq kuuk
North Star Island	North Star Qikiqtaq
NPR-A	NA
Nuiqsut	Nuiqsut
Nunavak Creek	Nunavaam kuuåuuraq
Ocean Point	NA
Okpilik River	Ukpilik kuuk
Old Man Store	NA
Oliktok Point	Uuliktuq nuvuåak
Paqta	Paqta
Pingok Island	Piÿu qikiqtaq
Point Barrow	Nuvuk
Point Brower	Agliåunitaq
Point Gordon	Nuvuk Gordon
Point Hopson	Nuvuk Hopson
Point McIntyre	NA
Point Sweeney	NA
Point Thomson	NA
Poko Lagoon	NA
Pole Island	NA
Prudhoe Bay	Prudhoe Bay
Putuliguyuk River Delta Overlook	Putuliåuyuk kuuk
Sadlerochit Mountains	Iååich Saliåutchi-mi
Sagavanirktok Creek	Saåvagniåtuuq kuugauraq
Sagavanirktok River	Saåvagniåtuuq kuuk
Sakhalin Island	NA
Sentinel Hill	NA
Shaviovik River	Savviuåvik kuuk
Shublik Mountains	NA
Smith Bay	Mittituaq
Spy Island	NA
St. Lawrence Island	NA
Staines River	NA
Stockton Islands	NA
Tamayariak River	Tamaåiaq kuuk
Tapkaurak Point	Tapqauraq nuvuk
Teshekpuk Lake	Tasiqpak Narvaq

Table 1: Place Names	
Place Name	Iñupiaq Name
Thetis Island	NA
Tigvariak Island	Tigvaåiaq qikiqtaq
White Hills	NA
Wood's Camp	Woods-kut Nunaÿat or Niåliq

Table 2: Plants		
Common Name	Scientific Name	Iñupiaq Name
Vascular Plants		
Boreal alopecurus	*Alopecurus alpinus*	
Wideleaf polargrass	*Arctagrostis latifolia*	
Pendantgrass	*Arctophila fulva*	
Boreal sagebrush	*Artemisia arctica*	Sargiåruaq
Field sagewort	*Artemisia borealis*	
Pacific alpine wormwood	*Artemisia glomerata*	
Alpine milkvetch	*Astragalus alpinus*	
Tundra milkvetch	*Astragalus umbellatus*	
Holm's reedgrass	*Calamagrostis holmii*	
Yellow marsh marigold	*Caltha palustris*	
Water sedge	*Carex aquatilis*	
Darkbrown sedge	*Carex atrofusca*	
Bigelow's sedge	*Carex bigelowii*	
Fragile sedge	*Carex membranacea*	
Shortleaved sedge	*Carex misandra*	
Round sedge	*Carex rotundata*	
Curly sedge	*Carex rupestris*	
Rock sedge	*Carex saxatilis*	
Hoppner's sedge	*Carex subspathacea*	
Bear sedge	*Carex ursina*	
White Arctic mountain heather	*Cassiope tetragona*	Pilåaurat
Bering chickweed	*Cerastium beeringianum*	
Arctic daisy	*Chrysanthemum arcticum*	
Entireleaf daisy	*Chrysanthemum integrifolium*	
spoonwort	*Cochlearia officinalis*	
Tufted hairgrass	*Deschampsia caespitosa*	
Ellesmere Island whitlow grass	*Draba subcapitata*	Naurriat
Entireleaf mountain-avens	*Dryas integrifolia*	
Fisher's tundragrass	*Dupontia fisheri*	
Sand ryegrass	*Elymus arenarius*	
Black crowberry	*Empetrum nigricans*	Paunåaq, or Asiaq
Dwarf fireweed	*Epilobium latifolium*	
Field horsetail	*Equisetum arvense*	
Variegated scouringrush	*Equisetum variegatum*	
Muir's fleabane	*Erigeron muirii*	Naurriat
Buff fleabane	*Erigeron ochroleucus*	Naurriat

Table 2: Plants		
Common Name	Scientific Name	Iñupiaq Name
Tall cottongrass	*Eriophorum angustifolium*	
Red cottongrass	*Eriophorum russeolum*	
White cottongrass	*Eriophorum scheuchzeri*	
Tussock cottongrass	*Eriophorum vaginatum*	
Arctic alpine forget-me-not	*Eritrichum aretioides*	
Northern fescue	*Festuca vivipara*	
Glacier avens	*Geum glaciale*	
Ross' avens	*Geum rossii*	
Seaside sandplant	*Honckenya peploides*	
Twoflowered rush	*Juncus biglumis*	
American dunegrass	*Leymus mollis ssp. mollis*	
Arctic woodrush	*Luzula arctica*	
Northern woodrush	*Luzula confusa*	
Apetalous catchfly	*Melandrium apetalum*	
Drummond's bluebells	*Mertensia drummondii*	Nautchiat
Twinflower sandwort	*Minuartia obtusiloba*	
Alpine mountainsorrel	*Oxyria digyna*	Quÿulliq
Blackish oxytrope	*Oxytropis nigrescens*	
Lapland poppy	*Papaver lapponicum*	
Macoun's poppy	*Papaver macounii*	
Hairy lousewort	*Pedicularis hirsuta*	Itkiliaåruk
Woolly lousewort	*Pedicularis kanei*	
Sudetic lousewort	*Pedicularis sudetica*	
Arctic sweet coltsfoot	*Petasites frigidus*	Mapkutitaaåruaq
Arctic bluegrass	*Poa arctica*	
Glaucus bluegrass	*Poa glauca*	
Hartz's bluegrass	*Poa hartzii ssp. alaskana*	
Meadow bistort	*Polygonum bistorta*	
Alpine bistort	*Polygonum viviparum*	
Stipulated cinquefoil	*Potentilla stipularis*	Naurriat
Northern primrose	*Primula borealis*	
Arctic alkaligrass	*Puccinellia arctica*	
Tundra alkaligrass	*Puccinellia langeana*	
Creeping alkaligrass	*Puccinellia phryganodes*	
Vahl's alkaligrass	*Puccinellia vahliana*	
Largeflowered wintergreen	*Pyrola grandiflora*	
Snow buttercup	*Ranunculus nivalis*	
Snow pearlwort	*Sagina intermedia*	

Table 2: Plants		
Common Name	Scientific Name	Iñupiaq Name
Arctic willow	*Salix arctica*	Uqpik or Upqiich
Woolly willow	*Salix lanata*	Uqpik or Uqpiich
Oval leaf willow	*Salix ovalifolia*	
Skeletonleaf willow	*Salix phlebophylla*	
Tealeaf willow	*Salix pulchra*	
Net-leaved willow	*Salix reticulata*	
Least willow	*Salix rotundifolia*	Uqpik or uqpiich
Narrowleaf saw-wort	*Saussurea angustifolia*	
Yellow mountain saxifrage	*Saxifraga aizoides*	Naurriat
Nodding saxifrage	*Saxifraga cernua*	
Leafystem saxifrage	*Saxifraga foliolosa*	
Yellow marsh saxifrage	*Saxifraga hirculus*	
Purple mountain saxifrage	*Saxifraga oppositifolia*	
Heartleaf saxifrage	*Saxifraga punctata*	
Kjellman's groundsel	*Senecio atropurpureus*	
Marsh fleabane	*Senecio congestus*	
Moss campion	*Silene acaulis*	
Saltmarsh starwort	*Stellaria humifusa*	
Umbrella starwort	*Stellaria umbellata*	Naurriat
Pygmy aster	*Symphyotrichum pygmaeum*	
Spike trisetum	*Trisetum spicatum*	
Lingonberry	*Vaccinium vitis-idaea*	Kimmiÿñaq
merckia	*Wilhelmsia physodes*	
Nonvascular Plants		
Moss/Tussock		Maniq
Moss	*Aulacomnium sp.*	
Common green bryum moss	*Bryum pseudotriquetrum*	
Cetraria lichen	*Cetraria sp.*	
Reindeer lichen	*Cladina sp.*	Niqaat
Crustose lichen	*Crustose lichen*	
Arctic dactylina lichen	*Dactylina arctica*	Niqaat
Distichium moss	*Distichium sp.*	
Drepanocladus moss	*Drepanocladus sp.*	
Funaria moss	*Funaria hygrometrica*	
Bamberger's hypnum moss	*Hypnum bambergeri*	
Dust lichen	*Lepraria neglecta*	
Polytrichum moss	*Polytrichum commune*	
Scorpidium moss	*Scorpidium scorpioides*	

Table 2: Plants		
Common Name	Scientific Name	Iñupiaq Name
Yellow Moss	*Sphagnum Species (Peat)*	Nunavik
Yellow Moss	*Sphqgnum species*	Uåruq
Whiteworm lichen	*Thamnolia*	
Tomentypnum moss	*Tomentypnum nitens*	

Table 3: Mammals		
Common Name	Scientific Name	Iñupiaq Name
Terrestrial Mammals		
Moose	*Alces americanus*	Tuttuvak
Wolf	*Canis lupus*	Amaåuq
Collared lemming	*Dicrostony x gronlandicus*	Qiɤaÿmiutauraq
Wolverine	*Gulo gulo*	Qavvik
Brown lemming	*Lemmus trimucronatus*	Aviÿÿaq
Singing vole	*Microtus miurus*	Aviÿÿaq
Root vole (tundra vole)	*Microtus oeconomus*	Aviÿÿaq
Ermine (short-tailed weasel)	*Mustela erminea*	Itiåiaq
Least weasel	*Mustela nivalis*	Itiåiaq
Muskoxen	*Ovibos moschatus*	Umiÿmak
Caribou	*Rangifer tarandus*	Tuttu
Tundra shrew	*Sorex tundrensis*	Ugrugnauraq
Barren ground shrew	*Sorex ugyunak*	Ugrugnauraq
Alaska tiny shrew	*Sorex yukonicus*	Aviÿÿauraq
Arctic ground squirrel	*Spermophilus parryii*	Siksrik
Brown bear	*Ursus arctos*	Akɬaq
Arctic fox	*Vulpes lagopus*	Tiåiganniaq
Red fox	*Vulpes vulpes*	Kayuqtuq
Marine Mammals		
Bowhead whale	*Balaena mysticetus*	Aåviq
Minke whale	*Balaenoptera acutorostrata*	Aåviq
Fin whale	*Balaenoptera physalus*	Aåviq
Hooded seal	*Cystophora cristata*	Natchiq
Beluga whale	*Delphinapterus leucas*	Qiɤalugaq
Bearded Seal	*Erignathus barbatus*	Ugruk
Gray whale	*Eschrichtius robustus*	Aåviåɤuaq
Steller sea lion	*Eumetopias jubatus*	Ugrugruaq
Humpback whale	*Megaptera novaeangliae*	Aåviq
Narwhal	*Monodon monoceros*	Aåvisuaq
Pacific walrus	*Odobenus rosmarus divergens*	Aiviq
Killer whale	*Orcinus orca*	Aaålu
Ringed seal	*Phoca hispida*	Qaiåulik
Spotted seal	*Phoca largha*	Qasigiaq
Harbor porpoise	*Phocoena phocoena*	Aåvisuaq
Polar bear	*Ursus maritimus*	Nanuq

Table 4: Birds		
Common Name	Scientific Name	Iñupiaq Name
Geese & Swans		
Greater white-fronted goose	*Anser albifrons*	kigiyuk niålivailuk
Brant	*Branta bernicla*	Niålinåaq
Cackling goose	*Branta hutchinsii*	Niåliq
Snow goose	*Chen caerulescens*	Kaÿuq
Tundra swan	*Cygnus columbianus*	Qugruk
Dabbling Ducks		
Northern pintail	*Anas acuta*	Kurgaq
American wigeon	*Anas americana*	Qaugak
Northern shoveler	*Anas clypeata*	Qaugak
Mallard	*Anas platyrhynchos*	Ivugasrugruk
Diving Ducks		
Greater scaup	*Aythya marila*	Qaq‡ukpalik
Long-tailed duck	*Clangula hyemalis*	Aahaaliq
White-winged scoter	*Melanitta fusca*	Qaugak

1. Introduction

The ExxonMobil Development Company (the Applicant) proposes to construct an oil and gas development project at Point Thomson on the northern edge of Alaska's Arctic Coastal Plain (ACP) adjacent to the Beaufort Sea (ExxonMobil 2011a). The proposed project would include the discharge of fill material into 276.5 acres of jurisdictional waters of the United States (U.S.) as part of the construction of the facility. The discharge of fill material into waters of the U.S. requires a Department of the Army permit from the U.S. Army, Corps of Engineers (Corps) under Section 404 of the Clean Water Act (CWA).

As part of its permitting decision regarding the Point Thomson Project, the Corps must evaluate the compliance of the proposed project with the Section 404(b)(1) Guidelines (Guidelines)[1]. This document constitutes a draft of the Corps' Point Thomson Project evaluation of compliance with the Guidelines. This document has been prepared to serve three primary purposes:

1) To present the preliminary information that will ultimately be used as part of the Corps' 404(b)(1) compliance determination and decision-making process regarding the proposed Point Thomson Project

2) To inform the public of the Corp's decision-making process with respect to the 404(b)(1) compliance evaluation of the Point Thomson Project and to invite the public to participate and provide comments relevant to the Guidelines compliance evaluation.

3) To highlight gaps in information and issues of concern related to the Applicant's proposed Point Thomson project.

Notably, this draft Guidelines evaluation is based on the information contained in the Draft Environmental Impact Statement (Draft EIS), and is provided for information. The Corps will not finalize its Guidelines compliance determination regarding the Point Thomson Project permit application until after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS. After the Corps has published the Final EIS, a Record of Decision (ROD) will be issued describing the Corps' decision on the permit application and its determination of whether the Point Thomson Project complies with the Guidelines.

1.1 PROJECT BACKGROUND

The proposed Point Thomson Project would allow for the development of the Thomson Sand reservoir for hydrocarbon production and further exploration. Development of the project would include the fill of jurisdictional wetlands for the construction of a central gravel pad for wells and facilities, two lateral gravel pads for additional wells, an airstrip, a service dock, a sealift facility and barge mooring dolphins, a gravel mine site, infield gravel roads, and infield gathering pipelines. A 22-mile-long export pipeline would be constructed to transport hydrocarbon liquids from Point Thomson to the existing common carrier pipelines at the Badami Development to the west. The project would also include infrastructure such as communications towers and staging facilities at Badami, Prudhoe Bay, and Deadhorse. A complete description of the Applicant's proposed project appears in Section 2.4.3 of the Draft EIS

[1] 40 CFR 230. The Section 404(b)(1) Guidelines, prepared by EPA, are the substantive criteria used by the Corps for the evaluation of a Section 404 permit.

1.1.1 Project Area

The proposed project is located at Point Thomson on the coast of Lion Bay and the Beaufort Sea, 60 miles east of Deadhorse and Prudhoe Bay and 60 miles west of the village of Kaktovik. The project area is defined to extend eastward from Deadhorse to the Staines River, and from the lagoon side of Flaxman Island and the Maguire Islands along the Beaufort Sea coast to approximately 8 miles south of the coast line. Most of the Thomson Sand Reservoir is offshore under state coastal waters, while most of the proposed facilities would be located on land. The western boundary of the Arctic Refuge is approximately 2 miles from the easternmost extent of the proposed project. An export pipeline and transportation routes would extend from the Point Thomson facilities to existing facilities to the west. There are currently no pipelines or permanent roads leading to the project area from the industrial facilities elsewhere on the North Slope. The Point Thomson Project would be the first permanent oil and gas infrastructure in the remote region of the eastern North Slope.

Ecosystems on the North Slope are shaped by the extreme conditions of the climate. The average minimum winter temperature in the project area of -24^{O}F while in the summer, the average maximum temperature is only 55^{O}F despite continuous daylight. The project area is covered with snow for about 8 months of the year; however, snow may fall at any time of the year. Soils in the project area are characterized by thick permafrost, which leads to waterlogging of surface soils. As a result, the Point Thomson area is characterized by extensive wetlands and water bodies. Less than one percent of the mapped project area is comprised of uplands (see Section 3.8m of the Draft EIS). Drainage in the project area is generally north and occurs via wetlands, small streams, larger streams, and rivers. Out of channel sheetflow is also common during spring breakup and peak water flow. The primary streams, rivers, and lakes provide habitat for anadromous and resident fish. The project area also provides habitat for numerous species of birds and terrestrial and marine mammals.

1.2 THE CORPS' AUTHORITY AND SCOPE OF ANALYSIS

1.2.1 Section 404 of the Clean Water Act

Many activities that impact wetlands and water bodies of the United States (U.S.) are subject to the jurisdiction of the Corps under Section 404 of the CWA and Section 10 of the Rivers and Harbors Act (RHA) of 1899. Under Section 404 of the CWA, the Corps has authority to permit the discharge of dredged or fill material in waters of the U.S. while the authority to permit work and the placement of structures in navigable waters of the U.S. is delegated to the Corps under Section 10 of the RHA[2].

The permit application evaluation requirements of Section 404 of the CWA are guidelines developed by the Environmental Protection Agency (EPA) in conjunction with the Corps and codified in 40 CFR Part 230. Under Subpart B of the 404(b)(1) Guidelines, the Corps' evaluation of the Point Thomson Project is required to address four tests that the project must meet in order to receive a Section 404 permit. These tests include:

- **40 CFR 230.10 (a)**: Whether there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences. The alternative identified by this test is referred to as the *least environmentally damaging practicable alternative* or the LEDPA. The

[2] The authority to issue or deny permits related to actions under both the CWA and RHA is delegated to the Corps' District Commander by 33 CFR 325.8.

evaluation of the proposed Point Thomson project with respect to this compliance test may be found in Chapter 2, Finding of Practicable Alternatives;

- **40 CFR 230.10 (b):** Whether the discharge would violate any applicable state water quality standards, Section 307 of the CWA, the Endangered Species Act (ESA), or federal laws concerning marine sanctuaries. The evaluation of the proposed Point Thomson project with respect to this compliance test may be found in Chapter 3, Restrictions on Discharge;
- **40 CFR 230.10 (c):** Whether the discharge would cause or contribute to significant degradation of the waters of the U.S. The evaluation of the proposed Point Thomson project with respect to this compliance test may be found in Chapter 4, Finding of No Significant Degradation.
- **40 CFR 230.10 (d):** Whether appropriate and practicable steps have been taken which will minimize potential adverse impacts of the discharge on the aquatic ecosystem. The evaluation of the proposed Point Thomson project with respect to this compliance test may be found in Chapter 5, Minimization of Potential Adverse Impacts.

The evaluation of a proposed project under all four of the tests listed above constitutes a determination of compliance with the Guidelines.

While making a compliance determination, the Corps may gather information sufficient to support and make its decisions by soliciting comments from other Federal, Tribal, State, and local resource agencies and the public. The Corps, however, is solely responsible for reaching a decision on the merits of the permit application including determination of the project purpose, the extent of the alternatives analysis, which alternatives are practicable, the LEDPA, the amount and type of mitigation that is to be required, and all other aspects of the decision-making process (Corps 2009).

1.2.2 National Environmental Policy Act

Because the required permit authorization from the Corps is a major federal action, the Corps is also the lead federal agency in the preparation of an EIS required under National Environmental Policy Act (NEPA)[3]. The Corps is being assisted in the NEPA process by several Cooperating Agencies, including the EPA, U.S. Fish and Wildlife Service (USFWS), and the State of Alaska. Responsibilities of the Cooperating Agencies include assisting the Corps in identifying issues of concern and providing meaningful and timely comment and input throughout the NEPA process.

According to the Guidelines, the NEPA alternative and impact analysis should provide information sufficient for the evaluation of compliance with the Guidelines. As stated in the Guidelines "For actions subject to NEPA, where the Corps of Engineers is the permitting agency, the analysis of alternatives required for NEPA environmental documents, including supplemental Corps' NEPA documents, will in most cases provide the information for the evaluation of alternatives under these Guidelines." Similarly, the Corps' Standard Operating Procedures for the Corps' Regulatory Program state that "districts should not conduct or document separate alternatives analyses for NEPA and the 404(b)(1) Guidelines" (Corps 2009).

The Draft EIS was prepared by the Corps to meet the NEPA and Guidelines requirements under the Corps' regulatory program. The Corps developed the Draft EIS cognizant of the requirements of the

[3] Guidance for NEPA implementation under the Corps' regulatory program is published in Appendix B of 33 CFR Part 325.

Guidelines. Alternatives were developed so that the LEDPA should be included in the alternatives and their collective components, and no additional alternatives will need to be developed as part of the Corps' Guidelines evaluation process. Notably, this draft Guidelines evaluation is not intended to replace any of the findings or conclusions in the Draft EIS. Rather, this draft Guidelines evaluation document builds on the alternatives and impact analysis developed within the Draft EIS, with a focus on the specific decision-making framework required by the Guidelines.

As a result of the development of the Draft EIS within the context of the 404(b)(1) evaluation process, this draft Guidelines evaluation relies on the findings and conclusions of the Draft EIS. For example, the Draft EIS establishes the range of reasonable alternatives to the Applicant's proposed project. These alternatives provide a starting point for the Corps' practicability analysis under the Guidelines. The Draft EIS also analyzes the potential direct, indirect, and cumulative impacts of the development of the Point Thomson Project under each of the Draft EIS action alternatives. This analysis serves as the starting point for the Corps' evaluation of the impact of alternatives and alternative components to waters of the U.S. and special aquatic sites. Information from the Draft EIS is incorporated extensively into this draft Guidelines evaluation both by reference and through the direct use of information contained therein.

2. Finding of Practicable Alternatives (40 CFR 230.10 (a))

The first compliance test of the Guidelines states that:

> *Except as provided under Section 404(b)(2), no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences.*

The Guidelines define a practicable alternative as one that is "available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes (40 CFR 230.10 (a)(2))." This chapter will form the basis of the Corps' analysis of practicable alternatives for the Guidelines evaluation.

The first compliance test of the Guidelines establishes two presumptions that must be rebutted if a proposed project would have impacts to special aquatic sites[4] and waters of the U.S. First, the guidelines state that when an activity associated with the discharge of dredged or fill material in a special aquatic site does not require access or proximity to that special aquatic site to fulfill its basic purpose, then the activity is not "water dependent" and practicable alternatives that do not include impacts to special aquatic sites are presumed to exist unless clearly demonstrated otherwise. Second, the Guidelines also establish that all practicable alternatives to the proposed discharge which do not involve a discharge into a special aquatic site are presumed to have less adverse impact on the aquatic ecosystem, unless clearly demonstrated otherwise. The evaluation of the water dependency of the Point Thomson Project and the availability of practicable alternatives that do not involve special aquatic sites is discussed in Section 2.1.2 below.

After evaluating the water dependency of the proposed project, the Corps must then consider the full range of practicable alternatives that are capable of achieving the overall project purpose. The overall project purpose, as defined by the Corps, is discussed in Section 2.1.3. According to the Guidelines, the Corps' consideration of practicable alternatives should also consider:

i) Activities which do not involve a discharge of dredged or fill materials into waters of the U.S. or ocean waters; and

ii) Discharges of dredged or fill material at other locations in waters of the U.S. or ocean waters.

The evaluation of practicable alternatives in this section is based on the range of reasonable alternatives developed through the Draft EIS alternatives development process. As discussed above, the Draft EIS alternatives development process was implemented in a manner cognizant of the requirements of the Guidelines such that the range of reasonable alternative identified for the Draft EIS can provide a starting point for the Corps' practicability analysis under the Guidelines. Thus, Draft EIS alternatives form the basis from which the Corps will identify practicable alternatives and determine if the Applicant's proposed project is the least environmentally damaging practicable alternative (i.e. the LEDPA). The

[4] *Special aquatic sites are geographic areas, large or small, possessing special ecological characteristics of productivity, habitat, wildlife protection, or other important and easily disrupted ecological values. These areas are generally recognized as significantly influencing or positively contributing to the general overall environmental health or vitality of the entire ecosystem of a region (40 CFR 230.3).These include wetlands, sanctuaries and refuges, mudflats, vegetated shallows, coral reefs, and riffle and pool complexes.*

Draft EIS alternatives are discussed in Section 2.3 of this draft Guidelines evaluation. Discussion of the practicability analysis methodology and preliminary discussion on practicability themes can be found in Section 2.4.

2.1 PROJECT PURPOSE

Establishing the underlying purpose and need for the project is a key step in the evaluation of a project under the Guidelines. Corps' regulations require three ways of examining the underlying goals, or purpose, of a project:

1) The Applicant's stated purpose and need;

2) A "basic" purpose defined by the Corps specifically for addressing a project's water dependency;

3) An "overall" purpose, which is defined by the Corps and takes into account the Applicant's stated purpose and need (33 CFR 325 Appendix B).

These three statements of the project purpose and need form the basis by which the Corps will evaluate the project under the Guidelines, and were also used as part of identifying the project purpose for the NEPA process. The three statements are developed to meet distinct objectives within the Corps' evaluation of the project's compliance with the Guidelines, but may overlap to some extent.

2.1.1 Applicant's Stated Purpose and Need

The Applicant's stated purpose and need are discussed in detail in Section 1.2.1 of the Draft EIS and in the Applicant's Final Department of the Army Permit Application (ExxonMobil 2011a). The Applicant's stated purpose and need is an expression, typically in the Applicant's own words, of the underlying goals for a proposed project. The Corps takes an applicant's purpose and need into account when determining the Corps' overall purpose.

2.1.2 The Corps' Basic Project Purpose

The Corps defines the basic project purpose and uses it to determine water dependency. An activity is defined as not water dependent if it does not require access or proximity to, or siting within, a special aquatic site to fulfill its basic purpose (40 CFR 230.10(a)(3)). If an activity or project is not water dependent, alternatives that do not involve impacts to special aquatic sites are presumed to be available, and to be less damaging, unless clearly demonstrated otherwise.

The Point Thomson Project's basic project purpose, as defined by the Corps, is: 1) to produce and transport hydrocarbon liquids, and 2) to delineate and test for oil and natural gas extraction. The exploration, production, and extraction of hydrocarbon resources are not activities that require access or proximity to a special aquatic site to achieve their goal. Therefore, the Corps finds that the basic purpose of the project is not water dependent, which requires that the Corps evaluate the rebuttable presumption that practicable alternatives that do not involve special aquatic sites are available.

Although the Point Thomson Project is not water dependent, the Corps understands practicable alternatives that do not impact waters of the U.S. and/or special aquatic sites do not exist as a result of geographical and technological constraints on project siting. The Thomson Sand reservoir is located beneath wetlands and other waters of the US, with the majority of the reservoir being located offshore. Access to the hydrocarbon reservoir is constrained to a zone defined by the technological limits of

drilling. These limits constrain the location of potential drilling and well pads to on and offshore locations in the Point Thomson area and in close proximity to the Beaufort Sea Coastline.

As part of the Draft EIS alternative development process (see Section 2.2), the Corps and Cooperating Agencies examined a full range of alternatives to determine if practicable alternatives that do not involve special aquatic sites exist. The Corps and Cooperating Agencies excluded offshore development from further consideration due to the added environmental risk associated with offshore development and the uncertain regulatory environment as perceived during development of the Applicant's previous 2002 proposal for offshore development and following the Deepwater Horizon oil spill in the Gulf of Mexico (see Section 2.2.2 Viability Analysis). As a result, all reasonable alternatives considered by the Corps for the Draft EIS and the Guidelines analysis include onshore development near the coastline in the Point Thomson area.

The onshore locations in the Point Thomson area are characterized by extensive wetland and water body cover. Less than one percent of the Point Thomson project area has been identified as uplands. With the prevalence of special aquatic sites in the ACP and the geographical constraints on the location of the Point Thomson Project, it has been clearly demonstrated that impacts to special aquatic sites are unavoidable under all reasonable alternatives and a practicable alternative that does not involve special aquatic sites does not exist. Thus, the Corps may authorize the proposed project, although it is not defined as water dependent, provided the activity is in compliance with other Guidelines requirements, that the action is not contrary to the public interest, and that all other applicable regulatory requirements are met (33 CFR 325).

2.1.3 The Corps' Overall Project Purpose

The Corps uses the overall project purpose to define alternatives for evaluation in the EIS and to determine if the Applicant's proposed project is the LEDPA. According to Corps' guidance, the overall purpose must be specific enough to define the Applicant's project, but not so restrictive as to preclude all discussion of alternatives to the Applicant's proposed project (Corps 2009). The Point Thomson Project's overall project purpose as defined by the Corps is:

1) To produce hydrocarbon liquids from the Thomson Sand reservoir; and
2) To further evaluate and delineate the Thomson Sand reservoir and evaluate the Brookian Group sandstones.

See Draft EIS Section 1.2.3 for additional discussion of the Corps' overall purpose.

2.2 ALTERNATIVES DEVELOPMENT

Having established the basic and overall purposes of the Point Thomson Project, the Corps then conducted a multistep alternatives development process as part of the NEPA process and to initiate evaluation of the proposed project under the first testing requirement of the Guidelines. As part of this process, the Corps and Cooperating Agencies developed and screened a full range of alternatives in light of the overall project purpose described in Section 2.1, Project Purpose. The goal of this process was to consider the broadest range of possible alternatives and to identify the range of reasonable alternatives that could meet the overall project purpose and that would advance for comparative analysis in the Draft EIS. The intent of the iterative process was to eliminate infeasible and unreasonable concepts and alternatives as early in the process as practical to allow the Corps and the Cooperating Agencies to focus

on more feasible concepts and alternatives. Alternative evaluation criteria for each step were identified early in the alternatives development process.

As a result, the range of reasonable alternatives identified by the Corps in the Draft EIS forms the starting point for the evaluation of practicable alternatives to Applicant's proposed project and determination if the Applicant's proposed project is the LEDPA. By examining the full scope of possible alternatives and systematically narrowing down potential alternatives to incorporate all reasonable alternatives in the Draft EIS, the Corps believes that it has captured all of the alternatives necessary to determine whether the Applicant's proposed project is the LEDPA.

Furthermore, the Corps structured the Draft EIS development process to allow for the consideration of alternative components within the context of the Draft EIS alternatives (e.g. infield ice roads, a 3,700 ft long airstrip, no barge access). This provides the Corps with the flexibility to evaluate the existence of practicable alternative components to elements of the Applicant's proposed project in the Corps' determination of whether or not the Applicant's proposed project is the LEDPA.

The Draft EIS alternative development process is described in Sections 2.2.1 through 2.2.3 below.

2.2.1 Conceptual Themes and Component Options

The initial step in the Draft EIS alternative development process was identification of possible alternative concepts capable of achieving the overall purpose of the project. During public scoping, a number of potential concerns and issues associated with the Point Thomson Project were identified and many alternative concepts for addressing the project purpose were suggested. The Corps and Cooperating Agencies used those suggestions to develop a broad set of nine alternative conceptual themes:

- Concept 1: No Action - as required by the CEQ guidelines
- Concept 2: Applicant's Proposed Action
- Concept 3:Minimizing Coastal Impacts
- Concept 4: Minimizing Infrastructure
- Concept 5: Maximizing Reservoir Access
- Concept 6: Limiting Activity Near the Refuge
- Concept 7: Maximizing Production
- Concept 8: Minimizing Onsite Activity
- Concept 9: Accommodating Significant Future Activity

Different component options, including alternative facility layouts, equipment, and strategies that could be used with different conceptual themes were also discussed for their ability to help meet the purposes of the proposed project and minimize impacts with the end goal of creating feasible concepts. Specific details of all of these conceptual themes and components can be found in Sections 2.2.1, Conceptual Theme Development and 2.2.2, Component Options, of the Draft EIS.

2.2.2 Viability Analysis

The identified alternative concepts and components were assessed based on their viability, which incorporated their ability to meet the Corps overall purpose; the technological feasibility of the concept or component; the extent to which the concept or component would ultimately accommodate full-field development; and a general assessment of the concept's environmental risks. The viability analysis also considered if the theme or component seemed reasonable in terms of past permit experience such as whether similar projects have been permitted in the past, and whether a particular theme or concept was distinct from other concepts. Table 2.1 summarizes the findings of the viability analysis for each conceptual theme.

Based on the viability analysis, the following four conceptual themes were eliminated from further consideration:

- Concept 5: Maximizing Reservoir Access, which would have included offshore development, was eliminated due to the added environmental risk of offshore development and the uncertain regulatory environment surrounding offshore oil and gas development following the April 2010 Deepwater Horizon oil spill in the Gulf of Mexico. It was also determined that currently available long-reach directional drilling would allow sufficient access to the offshore reservoir from an onshore location, making the offshore drilling proposed in Concept 5 unnecessary.
- Concept 8: Minimize Onsite Activity was eliminated from further consideration because it was deemed to be technologically infeasible. Locating personnel and processing infrastructure at BP Exploration, Inc's Badami facility, west of the Point Thomson unit, would require the compression of gas to extremely high pressures to transport the gas over 20 miles back to Point Thomson and still maintain the required wellhead pressure of 10,000 psig. The necessary gas compression would require increased fuel consumption for electric power, resulting in additional air emissions, and would increase the risks associated with pipeline failure (see RFI 64 in Appendix D of the Draft EIS).
- Concept 6: Limiting Activity near the Arctic Refuge did not satisfy the project's overall purpose of fully delineating and developing the reservoir as eliminating an eastern well site would prevent access to approximately one-third of the known gas resource.
- Concept 9: Accommodating Significant Future Development was eliminated because it was deemed not sufficiently distinct from Applicant's Proposed Action (Concept 2).

Table 2.1 Viability Analysis Results								
	Satisfies the Purpose and Need to:					Seems Reasonable in Terms of Permit Experience		
The Concept	Produce Condensate	Delineate the Reservoir	Evaluate the Resource	Technologically Feasible	Allows for Full-field Development	Positive Regulatory Precedent	Potential Benefits Support Additional Analyses	Unique and Distinct from Other Concepts
Concept 1: No Action	No	No	No	Yes	No	N/A	N/A	Yes
Concept 2: Applicant's Proposed Action	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Concept 3: Minimize Coastal Impacts	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Concept 4: Minimize Infrastructure	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Concept 5: Maximize Reservoir Access	Yes	Yes	Yes	Yes	Yes	No	No	Yes
Concept 6: Limit Activity Near the Arctic Refuge	Yes	No	No	Yes	No	Yes	Yes	Yes
Concept 7: Maximize Production	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Concept 8: Minimize Onsite Activity	Yes	Yes	Yes	No	Yes	No	No	Yes
Concept 9: Accommodate Significant Future Development	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No

In addition to eliminating conceptual themes, the viability analysis also eliminated several project components from further consideration. These included pipelines buried in the tundra, the use of the power generated at Badami, the development of an automated facility with offsite controls, and buried subsea export pipelines. These components were eliminated for a variety of reasons including technological challenges and increased environmental risks. A more detailed discussion of each of the conceptual themes and components eliminated from further consideration can be found in Section 2.2.4, Concepts and Component Options Eliminated, of the Draft EIS.

2.2.3 Range of Reasonable Alternatives

Out of the conceptual theme and viability analysis process, the following six alternatives were brought forward as the full range of alternatives for consideration in the Draft EIS:

- Alternative 1: No Action (based on Concept 1)
- Alternative 2: Applicant's Proposed Action (based on Concept 2)
- Alternative 3a: Inland Pads with Gravel Access Road (based on Concept 3)
- Alternative 3b: Inland Pads with Seasonal Ice Access Road (based on Concept 3)
- Alternative 4: Coastal Pads with Seasonal Ice Roads (based on Concept 4)
- Alternative 5: Coastal Pads with Centrifugal Compression (based on Concept 7).

See Section 2.3, Screening of the Full Range of Alternatives, of the Draft EIS for additional discussion of each of these alternatives.

Following their identification, the alternatives were further refined through a comparative screening process that included information gained through a series of workshops; the Request for Information process (see Appendix D of the Draft EIS); and technical review by the Applicant addressing logistics, technical capabilities, and other project-related details. Based on this information, the criteria developed for the viability analysis of the conceptual themes was reapplied to identify and eliminate components that appeared to satisfy the purpose of the project but that, after additional research, did not enable production, delineation, or resource evaluation. Alternatives and component options that were not technologically feasible or were redundant also were eliminated from further consideration. The comparative screening processes further refined which alternatives and/or component options would best meet the overall project purpose as defined by the Corps, and ultimately resulted in the range of reasonable alternatives used in the Draft EIS alternative impact analysis.

During the comparative screening process, Alternative 5: Coastal Pads with Centrifugal Compression was eliminated because it was deemed to be too similar to Alternative 2: Applicant's Proposed Action. Additionally, several components options, including gathering lines buried in infield roads, ice airstrip extension, light-duty infield roads, centrifugal compression, and use of seasonal infield ice roads only, were also eliminated for redundancy with other components, high risk of environmental impacts, logistical constraints, unproven technology, and technical infeasibility. A more detailed discussion of the alternative and components eliminated from further consideration can be found in Section 2.3.1, Alternatives and Components Eliminated, of the Draft EIS.

From the comparative screening process, five reasonable alternatives were carried forward for full evaluation. Alternatives were renamed at this point in the process in order to more clearly differentiate them within the Draft EIS. The reasonable alternatives were identified as follows:

- Alternative A: No Action (formerly Alternative 1)

- Alternative B: Applicant's Proposed Action (formerly Alternative 2)
- Alternative C: Inland Pads with Gravel Access Road (formerly Alternative 3a)
- Alternative D: Inland Pads with Seasonal Ice Access Road (formerly Alternative 3b)
- Alternative E: Coastal Pads with Seasonal Ice Roads (formerly Alternative 4)

The four action alternatives B, C, D, and E meet the Corps' overall purpose and are discussed in more detail below and in Section 2.4 of the Draft EIS.

2.3 DRAFT EIS ALTERNATIVES DESCRIPTIONS

As discussed in Section 2.2, Alternatives Development, the Corps led the Draft EIS alternatives development and screening process, cognizant of the requirements of both NEPA and the Guidelines. The four Draft EIS action alternatives that emerged from the alternatives development and screening process establish the range of reasonable alternatives that form the starting point for the Corps' analysis of practicability and under the Guidelines. The Corps seeks public comment on the merits of each of the Draft EIS alternatives and individual components with the alternatives as it relates to the Guidelines evaluation for its use in determining whether the Applicant's proposed project is the LEDPA. The following sections provide descriptions of each of the four action alternatives and their components.

2.3.1 Components Common to All Draft EIS Alternatives

All action alternatives would result in the construction of facilities needed to explore and recover hydrocarbon liquids. All action alternatives would include the following components: gravel pads to support drilling and production operations; gravel and/or ice roads and airstrips to support transportation needs; and export and infield pipelines. While the action alternatives are distinct alternatives, several components are common to all action alternatives. These commonalities are largely due to the use of standard North Slope construction and mitigation methods. Components common to all action alternatives are discussed below, as well as in Section 2.4.2, Components Common to All Action Alternatives, of the Draft EIS.

2.3.1.1 Wells and Production Pads

The gravel pads proposed in all four action alternatives would require the discharge of material into the waters of the U.S., an activity under the jurisdiction of the Corps under Section 404 of the CWA. Each alternative has a unique configuration of pads for drilling and production. However, each action alternative would have a minimum of four production wells, one injection well, and one disposal well arranged as follows: one production and one injection well on the Central Well Pad, one production well on the East Pad, one production well on the West Pad, one additional production well on one of the three well pads, and one disposal well on the Central Processing Pad.

Each of the production wells would be designed to access the reservoir using both traditional and long-reach directional (LRD) drilling. The current 13,000 foot limit of existing LRD drilling technology would enable each of the action alternatives to access offshore portions of the reservoir from onshore well pads. The wells on the East and West Pads would be used initially to delineate and evaluate the reservoir, and to determine whether the rim of oil surrounding the gas reservoir is viable for production.

In each alternative, the East and West Pads would be connected to the Central Processing Facility (CPF) by infield gathering pipelines. The CPF would be located either on the Central Well Pad (Alternatives B and E) or on a separate Central Processing Pad (Alternatives C and D). The CPF is where product from the wells would be separated and liquid condensate would be recovered. The Central Processing Pad

would also accommodate living quarters and support facilities, warehouse and storage space, a water treatment and waste disposal system, communication facilities, power generation, diesel fuel storage tanks, and an emergency boat launch. Most of the facility infrastructure would be transported to the site as prefabricated modules requiring minimal construction in place. The size, number, and transportation method of the modules varies by alternative. See Draft EIS Section 2.4.2.1, Wells and Production Pad for more detailed descriptions of the each of the pads and their components.

2.3.1.2 Export and Infield Pipelines

Each alternative would include a configuration of infield gathering lines to bring produced fluids from the well pads to the CPF for processing and an export pipeline to bring hydrocarbon products to the Trans-Alaska Pipeline System (TAPS). All pipelines would be elevated on vertical support members (VSM) with a minimum 7- foot clearance between the bottom of the pipe and the tundra surface. The 7-foot clearance would allow free passage by wildlife and subsistence hunters on snow machines. The length, route, and number of pipelines needed vary by alternative.

2.3.1.3 Access and Transportation Infrastructure

Personnel, equipment, and supplies would be transported to and within Point Thomson by land, air, and in some alternatives, sea. Most modes of transportation are season dependent, which can greatly affect the logistics and timing of project construction.

Each alternative would use seasonal ice roads for access to Point Thomson during construction, as well as to enable construction of gravel infrastructure and pipeline. Ice roads are one of the fundamental ways to get goods, equipment, and people around the North Slope in winter. Ice road construction is weather-dependent, and generally begins in late December or early January. The main ice road would generally be ready by mid-February and would be thick enough to accommodate normal trucks for up to 300,000 pounds. For drill rig and module transport, the ice road would need to be thicker and wider, and would generally take an additional three weeks to prepare. Ice road are generally available for use until late April.

Airplane and helicopter traffic are key elements for the transport of personnel, supplies, and emergency response equipment. Each alternative includes a gravel airstrip for year-round, fixed-wing aircraft access to Point Thomson. While the size and location of the airstrip would vary by alternative, each would include a helipad, runway lighting with buried power lines, an airport control building, an airstrip apron, and navigational aid pads, adjoining the airstrip. Typically-sized aircraft using the runway would include the 19-passenger Beechcraft 1900D or a deHavilland Twin Otter for personnel and light freight transport. The airstrips proposed in all four action alternatives will require the discharge of material into the waters of the U.S., an activity under the jurisdiction of the Corps under Section 404 of the CWA.

The number, type, and route of gravel roads would depend upon the alternative, though each alternative includes a road from the Central Processing Pad to the airstrip to accommodate frequent personnel transport. The gravel roads in each alternative would have an average footprint width of 58 feet (HDR 2011a). Culverts would be installed after the initial road installation and would be designed for a 50-year flood event. Additional culverts would be added to the roads in late summer if observations during spring breakup identify areas where the road infrastructure does not allowing sufficient water flow. Bridges would consist of pipe piling supports with sheet piling abutments and precast concrete decks. The road routes in each alternative would determine the number and location of bridges for that alternative. Infield gravel roads would, wherever possible, be located a minimum of 500 feet from elevated pipelines, in

accordance with the USFWS, ADF&G, NSB, and AOGA Steering Committee's 1994 caribou mitigation guidelines (Cronin, et al. 1994). The gravel roads proposed in all four action alternatives will require the discharge of material into the waters of the U.S. under the jurisdiction of the Corps under Section 404 of the CWA.

Barging is an additional form of transportation to the Point Thomson site that is incorporated into Alternatives B and E only. Marine access enables the transport of equipment and materials to Point Thomson during the open water seasons when ice roads are not available or when heavy loads exceed aircraft capacity. Depending on nearshore ice conditions, the open water season is generally from late July/early August through the end of September. This season is not entirely available for barging due to subsistence whaling activity. The Applicant has voluntarily signed a Conflict Avoidance Agreement with the Alaska Eskimo Whaling Commission that affects barging activity. Through the agreement, the Applicant agrees to avoid barging during the Village of Kaktovik's and Nuiqsut's whaling season (generally from August 24 to September 23), to the greatest extent possible, in order to minimize potential impacts to subsistence hunting (ExxonMobil 2011b). When barging during the whaling season is needed, the Applicant will follow the protocols outlined in the Conflict Avoidance Agreement to avoid or minimize interactions with whaling vessels and whales.

In Alternatives B and E, two forms of barging would be available to access Point Thomson: coastal barges and oceangoing (sealift) barges. Coastal barges would be used to deliver small modules, foundation materials, and construction equipment to the project site from Deadhorse. Coastal barging would also provide a means for the resupply of bulk materials and for the removal of wastes and excess equipment. Coastal barging would require the construction of a 70 foot long service pier and four mooring dolphins as well as dredging and screeding of the sea floor to provide a stable base for barge offloading. Sealift barges are considerably larger than coastal barges and can carry heavier loads with relatively shallow draft. These loads would include larger processing and prefabricated facility modules, and even portions of the drill rig. Barges would transport equipment to Point Thomson from suppliers worldwide. To unload sealift barges, a sealift facility would be constructed adjacent to the service pier at the Central Pad. This would include an offloading bulkhead and offshore mooring dolphins to secure the barges as they are offloaded at the site.

As part of the bulkhead construction the seafloor would require dredging and screeding to safely ground the large oceangoing barges sufficiently close to the bulkhead. The seafloor would be dredged and screeded approximately 300 feet northward of the service pier. For the sealift barge facility, dredging and subsequent screeding would begin approximately 40 to 60 feet from the bulkhead and proceed north approximately 500 feet. Removed seafloor sediments would be placed along the shoreline to the west of the Central Pad location. Approximately 1,500 cubic yards would be dredged during each year of construction to support use of the service pier and sealift barge facility (ExxonMobil 2011b). Dredged material disposal in waters of the U.S. falls under the Corps jurisdiction under Section 10 of the Rivers and Harbors Act.

2.3.1.4 Support Facilities

In addition to the main project facilities, numerous support facilities are required for the construction and operation of all of the action alternatives. These facilities include the development of a gravel mine site, access to and use of a potable freshwater source, storage space, and temporary construction camp space. In addition, all action alternatives would require approximately 1.5 million gallons of diesel fuel supplied

by truck over the course of the first winter construction season and stored in 60 stackable, 25,000-gallon temporary fuel tanks on the existing Central Pad footprint.

In all action alternatives, the primary gravel source for the project would be from a new gravel mine site. The size of the new gravel mine would be determined by the gravel requirements of the alternative. The mine's precise location and layout would depend upon both the alternative and the results of an analysis of core samples prior to construction of the mine. To access the gravel, a surface layer of organic and inorganic material called "overburden" would need to be removed and stockpiled on seasonal ice pads. Mining operations would include blasting and mechanical excavation to a depth ranging between 40 and 50 feet below the overburden, depending upon the gravel content of the mine. After construction is completed, the new gravel mine site would be rehabilitated through the replacement of the overburden, the creation and contouring of stable side walls, and then by being allowed to fill with water. Once filled with water, the new mine site reservoir could be used as either a primary or secondary source of water for the project, depending upon the alternative. The discharge of excavated (dredged) material, including stockpiling, in jurisdictional wetlands, falls under the permitting authority of the Corps under Section 404 of the CWA.

2.3.1.5 Logistics and Sequencing

The logistics and sequencing of the alternatives vary greatly, though each follows a standard pattern of phasing within the project. Construction in each action alternative would begin with a mobilization, using various modes of transportation, to move equipment, supplies, and personnel to the project site. The construction phase of project development would include gravel mining; infrastructure installation, including roads, pads, airstrips, and pipelines; and facility modules transport, installation, and commissioning. In each alternative, the drill rig would arrive onsite once the well pads were ready for use, generally during the last year of onsite construction, initiating the natural gas drilling phase. The operations phase would begin as soon as the first wells were complete and sending condensate to the CPF. In each alternative, first production would occur while the final wells are being drilled.

2.3.2 Alternative B: Applicant's Proposed Action

Alternative B would configure the drilling and production facilities onto three gravel pads located near the coastline and incorporating portions of two existing gravel pads (see Figures 2.4-5 and 2.4-6 in the Draft EIS). A 22-mile long export pipeline would be constructed from the Central Pad to the common carrier pipeline at Badami. The proposed pipeline route from Point Thomson to Badami is generally located more than a mile inland. Approximately 10 miles of infield gathering pipeline would be constructed to transport produced hydrocarbons from the East and West Pads to the Central Processing Facility located on the Central Pad.

Access to Point Thomson in Alternative B would provided by ice road, air, and coastal and sealift barge during construction and primarily by air and coastal barge during operations. During construction, large modules would be brought to Point Thomson via sealift barge and small modules would be trucked to Prudhoe Bay and then transported to Point Thomson via ice road. Some modules may be staged in Deadhorse awaiting ice road opening. A 5,600-foot by 200-foot gravel airstrip and helipad would be constructed south of the Central Pad, approximately 3 miles inland from the coast. The runway would be designed to provide landing and take-off capabilities for a Lockheed C-130 Hercules cargo plane (minimum 5,000 ft length plus a 600 foot safety buffer zone) for maintenance and servicing of large equipment or potentially for emergency response. Most aircraft that would commonly land to Point Thomson would be smaller. Transportation within the Point Thomson area would be provided by ice road

during initial construction, followed by 12 miles of infield gravel roads that would connect the gravel pads, gravel mine, airstrip, and water source. The infield gravel roads would require nine stream crossing structures (culverts or bridges) to cross creeks and small tundra streams.

Most gravel for Alternative B would come from the new gravel mine site located approximately 2 miles south of the Central Pad and just north and east of the proposed airstrip. It is estimated that approximately 2.2 million cubic yards of gravel would be removed from the 58-acre mine site. After completion of mining activity, the gravel mine site would be rehabilitated. Over the course of 5 to 11 years, natural sheetflow would fill the mine site and create a reservoir that could be used as a permitted backup water supply in future years (ExxonMobil 2011b).

In Alternative B, pipeline and infrastructure construction would be executed over three winter construction seasons. The drilling program would take place over approximately 2.5 years. If a permit were issued for this alternative, facility start up would be expected to occur in year 4 following the ROD. Additional detail regarding infrastructure and logistics of Alternative B can be found in Section 2.4.3, Alternative B: Applicant's Proposed Action, of the Draft EIS.

2.3.3 Alternative C: Inland Pads with Gravel Access Road

The intent of Alternative C is to minimize impacts to coastal resources such as marine mammals, marine fish, subsistence activities, and coastal processes, and to avoid potential impacts to the proposed project from coastal erosion. To minimize impacts, this alternative would move project components inland and as far away from the coast as practicable and feasible (see Figures 2-11 and 2-12 in the Draft EIS). This alternative also attempts to minimize impacts to hydrologic connectivity by moving linear facilities, such as infield roads, further inland and orienting them in a north/south direction in alignment with the areas' predominant hydraulic gradient. To provide year-round access to Point Thomson, this alternative also includes the construction of a 44-mile, all-season gravel road from Point Thomson to the Endicott Spur Road (see Figures 2.4-14 and 2.4-15 in the Draft EIS).

Alternative C would locate the drilling and production facilities on four onshore gravel pads that would consist of a Central Well Pad, a Central Processing Pad, and two East and West pads. The East and West Pads would be located approximately 4 miles away from the Central Processing Pad and one-half mile inland. A 51-mile elevated export pipeline would be constructed from the Central Processing Pad to the existing Endicott common carrier pipeline, which connects to TAPS Pump Station No. 1. The pipeline alignment would parallel the all-season gravel road, approximately 500 feet south of the road. Alternative C would include approximately 9 miles of gathering pipelines connecting the East and West Pads to the Central Processing Pad, 3 miles of production pipeline from the Central Well Pad to the Central Processing Pad, and an additional 3 miles of high pressure injection pipeline from the Central Processing Pad back to the Central Well Pad.

Alternative C relies upon ice roads, gravel roads, and aircraft for transportation. It does not include barging or barge facilities to provide access Point Thomson. All modules would be transported to the site from Deadhorse by ice road. During construction, two main ice roads, an access road and a pipeline construction road, would need to be constructed between the Endicott Spur Road and Point Thomson to transport materials, supplies, and modules to and from Point Thomson. Due to an anticipated amount of heavy traffic the two ice roads would be connected via 35-foot-wide ice road bypass ties every mile to facilitate traffic flow. A 5,600-foot by 200-foot gravel airstrip and helipad would be constructed in the location of the former West Staines gravel airstrip. The runway would be designed to provide landing and take-off capabilities for a Lockheed C-130 Hercules cargo plane. Within Point Thomson, the 20 mile

infield gravel road network would be the primary means of in field transportation for personnel, materials, and equipment.

A unique feature of Alternative C is a new 44-mile all-season grave road that would be constructed to provide access to and from Point Thomson during drilling and operations. This road would be located between 3 and 8 miles south of the coastline and would generally follow the proposed Bullen Point Road Corridor, beginning at the Endicott Spur Road, south of the Badami common carrier pipeline (and east of the Kadleroshilik River), and continue eastward to Point Thomson. The infield and all-season access gravel roads would require 50 stream crossing structures (culverts or bridges) to cross rivers, creeks, and streams including three at major water bodies.

Gravel for Alternative C would be obtained from a new 66 acre gravel mine site located near the proposed Central Processing Pad. Approximately 2.9 million cubic yards of gravel would be removed from the mine. Before breakup in Year 3, the mine would be rehabilitated and allowed to fill with water from runoff. Construction of the gravel access road would also require up to five additional gravel mines, sited approximately every 10 miles along the road corridor. These additional mines would each be approximately 13 acres in size with accompanying 13-acre seasonal ice pads to store overburden.

In Alternative C, additional detailed engineering would be needed to design modules capable of transport overland to Point Thomson via ice road. If a permit were to be issued for this alternative, construction would be unlikely to begin until Year 3 following the ROD and would be executed over three winter construction seasons. The drilling program would take place over approximately four seasons. Facility startup is estimated to occur in Year 6. Additional detail regarding infrastructure and logistics of Alternative C can be found in Section 2.4.4, Alternative C: Inland Pads with Gravel Access Road, in the Draft EIS.

2.3.4 Alternative D: Inland Pads with Seasonal Access Road

The intent of Alternative D is to minimize impacts to coastal resources such as marine mammals, marine fish, subsistence activities and coastal processes, and to reduce potential impacts to the proposed project from coastal erosion. To minimize impacts, this alternative would move the project components inland and as far away from the coast as practicable and feasible (see Figures 2-16 and 2-17 in the Draft EIS). Alternative D is similar in design to Alternative C, but does not include the construction of or access by an all-season gravel road. Rather, ground access to and from Point Thomson in Alternative D would occur via an inland 48-mile seasonal ice road, running east from the Endicott Spur Road to the northern end of the Point Thomson project area (See Figures 2.4-21 and 2.4-22 in the Draft EIS).

The drilling and production facilities in Alternative D would be located in a four-pad configuration in a manner similar to Alternative C. The four gravel pads and airstrip would be connected by an 18-mile gravel road network. The infield gravel roads would require seven stream crossing structures (culverts or bridges).

The infield gathering pipelines, production lines, and their supports would be the same as those described in Alternative C. The export pipeline would differ in that it would tie into the existing common carrier pipeline at Badami. The export pipeline would be 23 miles long and follow a route generally located more than 4 miles inland. Infield pipelines would be similar to those described in Alternative C.

In Alternative D, the ice road from the Endicott Spur Road and aircraft would be the two primary methods of transport to move materials, equipment, and personnel to and from Point Thomson.

Alternative D does not include barging or barging facilities to access Point Thomson. All modules would be transported to the site from Deadhorse by ice road. At least three seasonal tundra ice roads would be built each year during construction to connect Point Thomson to Badami and then to the Endicott Spur Road. Similar to Alternative C, the parallel ice roads would be connected via 35-foot-wide bypass ties every mile along the two roads to facilitate traffic flow. A 5,600-foot by 200-foot gravel airstrip and helipad would be constructed one mile northeast of the former West Staines gravel airstrip. The runway would be designed to provide landing and take-off capabilities for a Lockheed C-130 Hercules cargo plane. Within Point Thomson, the 18-mile infield gravel road network would be the primary means of infield transportation for personnel, materials, and equipment.

The primary gravel source for the project would be a new 66-acre gravel mine site located less than 2 miles south of the Central Well Pad and near the proposed Central Processing Pad. Approximately 2.8 million cubic yards of gravel would be removed from the mine. Before breakup in Year 3, the mine would be closed and rehabilitated. An inlet structure would be constructed to divert water from an adjacent stream during spring breakup to fill the mine site for use as a new freshwater reservoir (HDR 2011b).

The logistics and sequencing for Alternative D would be similar to that described in Alternative C, though Alternative D would use an annual ice access road for to resupply its drilling and operations activities each year. This transportation method would extend the drilling program by one year relative to Alternative C and two years relative to Alternative B. If a permit were to be issued for this alternative, facility startup is expected to occur in Year 6 following the ROD. Additional detail regarding infrastructure and logistics of Alternative D can be found in Section 2.4.5, Alternative D, Inland Pads with Seasonal Ice Access Road, in the Draft EIS.

2.3.5 Alternative E: Coastal Pads with Seasonal Ice Roads

The intent of Alternative E is to minimize the development footprint to reduce impacts to wetlands and surrounding water resources. Alternative E would locate the drilling and production facilities onto a three-pad configuration similar to that of Alternative B, but that would consist of an enlarged Central Pad and two other ice-gravel combination pads at the East and West Pads (see Figures 2-19 and 2-20 in the Draft EIS). The gravel footprint of the East and West Pads would allow for adequate pad space for operations and would be supplemented with a multiseason ice pad extension to accommodate additional infrastructure needed during the drilling phase. The gravel footprint would also be reduced by the use of annually built, infield ice roads in lieu of constructing infield gravel roads to the East and West Pads (see Figures 2.4-26 and 2.4-27 in the Draft EIS).

Ten miles of infield gathering pipelines would be constructed to connect the East and West Pads to the CPF in a layout similar to that of Alternative B. The Central Pad would connect to the airstrip and C-1 storage pad and reservoir via a 4-mile gravel road. The infield gravel roads would require one stream crossing structure. Alternative E would include the construction of a 3,700-foot by 200-foot airstrip. This airstrip would not be capable of accommodating a C-130 Hercules cargo plane. Rather, the shortened airstrip would be capable of landing aircraft with a capacity of 5,000 lbs or 15 people.

The primary gravel source for the project would be a new gravel mine site located 2 miles south of the Central Pad. Approximately 1.7 million cubic yards of gravel would be removed from the mine. As described in Alternative B, the goal would be to complete gravel mining in two winter seasons, after which the mine would be rehabilitated. This new reservoir could be used as a secondary water source as needed during field life.

The logistics and sequencing of Alternative E would be similar to that described in Alternative B, although the limitations to drill rig transportation between the East and West Pad would extend the drilling schedule by two seasons. If a permit were to be issued for this alternative, facilities start up is estimated to occur in Year 5 following the ROD. Additional detail regarding infrastructure and logistics of Alternative E can be found in Section 2.4.6, Alternative E, Coastal Pads with Seasonal Ice Roads, in the Draft EIS.

2.4 ALTERNATIVES PRACTICABILITY ANALYSIS

Having established the full range of reasonable alternatives through the Draft EIS alternatives development process, the Corps must then evaluate the practicability of the alternatives to determine if a practicable alternative to the Applicant's proposed project exists which "would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences." (40 CFR 230.10(a))

To make this determination, the Corps will evaluate the Draft EIS alternatives and alternative components using the definition of practicability established by the Guidelines. As discussed in Section 2.2, Alternatives Development, the Corps believes that it has captured all of the reasonable alternatives and components necessary to determine whether the Applicant's proposed project is the LEDPA. The evaluation of detailed component alternatives within the Draft EIS alternatives also provides the Corps with additional flexibility to ensure that the full extent of practicable alternatives is considered when determining if the Applicant's proposed project is the least environmentally damaging alternative among all of the alternatives identified as practicable. The Corps may only issue a permit for the Applicant's proposed project if it is found to be the LEDPA.

The practicability analysis being conducted by the Corps is not intended to alter the conclusions reached by the Draft EIS for the NEPA process, nor need it incorporate alternatives or alternative components that were eliminated from consideration as part of the alternative development process in the Draft EIS. Rather, the purpose of the practicability analysis is to supplement the information and findings presented in the Draft EIS, to meet the needs of the alternatives analysis requirements of the Guidelines.

The discussion in this section provides the methodology by which the Corps will ultimately determine the practicability of the Draft EIS alternatives and alternative components including some practicability themes that have been identified as part of the Draft EIS alternatives development process. However, at this point in time, the Corps considers all Draft EIS alternatives and alternative components to be practicable and the Corps will not make a final determination on practicability until the issuance of a ROD. The Corps invites the public to review the practicability methodology and themes presented in this section. The Corps also solicits public comment on the practicability of the alternatives and components presented.

2.4.1 Practicability Analysis Methodology

The Guidelines provide a two-fold definition of a practicable alternative:

1. A practicable alternative is one that is available and capable of being done after taking into consideration cost, existing technology, and logistics.
2. The three practicability criteria (cost, existing technology, and logistics) apply in light of the overall project purpose.

Thus, in order to be practicable, an alternative must not only meet the three practicability criteria but must also fulfill the overall project purpose. The overall purpose of the Point Thomson project, as described in Section 2.1, is to:

- To produce hydrocarbon liquids from the Thomson Sand reservoir; and
- To further evaluate and delineate the Thomson Sand reservoir and evaluate the Brookian Group sandstones.

As part of its practicability analysis, the Corps is working with the Applicant to evaluate the logistical and technological constraints associated with the Draft EIS alternatives. The Applicant is uniquely positioned to help identify key differences between the four alternatives based on three years of engineering and planning related to the proposed Point Thomson Project, previous experience conducting exploratory drilling at the Point Thomson site, and global experience in hydrocarbon development projects.

In full compliance with NEPA guidelines, all information provided by the Applicant has been and will continue to be validated and verified by several third-party reviewers. Third-party reviewers are selected for their extensive experience constructing, operating, and managing similar hydrocarbon production facilities on Alaska's North Slope and their knowledge and familiarity of the oil and gas industry standard practices in Alaska. Third-party reviewers include experts in hydrocarbon facility design, existing technologies, costs, and logistics.

At this point in time, the Applicant has completed extensive analyses on existing technology and logistics as it relates to the practicability of the Draft EIS alternatives (ExxonMobil 2011c). Third-party reviews of the information provided by the Applicant have the found that the conclusions developed as part of the practicability analysis conducted by the Applicant were reasonable and presented a best-case scenario for the development of all action alternatives.

At this time, however, the Corps has not received information on estimated project cost that is sufficient to fully evaluate the practicability of the Draft EIS alternatives and components. This information is necessary to complete the practicability analysis and must be provided by the Applicant before a decision can be made on compliance with the Guidelines and a ROD can be issued. Due in part to the lack of information on cost, the Corps considers all Draft EIS alternatives and alternative components to be practicable.

2.4.2 Practicability Themes

While the Corps currently considers all Draft EIS alternatives and alternative components to be practicable under the Guidelines, several practicability themes have been identified during the development of the Draft EIS alternatives. These themes are likely to form the basis of the Corps' practicability analysis and evaluation of the Applicant's proposed project under the Guidelines.

2.4.2.1 Transportation Alternatives to the Point Thomson Site

The construction of the Point Thomson facility would require the transportation of production modules, construction materials and equipment, and personnel to and from the Point Thomson site. However, the harsh climate conditions and remote nature of the Point Thomson project lead to transportation constraints that have significant impacts on project logistics and costs for all alternatives. Currently, helicopter provides the only year-round access to the site. However, based on the Applicant's past experience at the site, helicopters are likely to be grounded 20 percent of the time due to weather concerns. Year-round,

fixed wing aircraft access would become available upon the completion of the gravel airstrip infrastructure planned as part of all action alternatives.

The Point Thomson area is accessible by ground transportation only in limited seasonal windows. Potential transportation methods under consideration include ice road (available January through April), barge (available July through September), and unrestricted tundra travel (available December and January). Within these availability windows, unpredictable weather and seasonal variations, such as lingering sea ice that delays the start of the barging season or winter storm surges that disrupts ice road construction may reduce available transportation windows even further. Outside of these availability windows, the Point Thomson site would be accessible only by air.

In addition to seasonal constraints, each transportation method has limitations in terms of load capacity. For example, a single sealift barge has the capability to transport a load of 4,000 tons while a regular tractor-trailer load, transported over an ice or gravel road is limited to about 40,000 lbs (~20 tons). The maximum loads of fixed wing and helicopter vary by aircraft type but range from 5,000 lbs (Twin Otter or Cessna) to 45,000 lbs (C-130 Hercules; ExxonMobil 2011c). Load capacities and restrictions on the size and shape of loads, influences the size of modules that can be prefabricated offsite and transported to Point Thomson for assembly and hookup. For example, using larger modules leads to greater gains in efficiency in transportation and assembly (ExxonMobil 2009). The result of reducing load capacity is that facility modules would need to be reduced in size and weight, but would increase in number, such that there more smaller loads required. These factors directly affect project logistics and costs.

The design, sequencing, and logistics detailed in the Applicant's proposed project (Alternative B) is the result of extensive front-end engineering and a modularization study conducted by the Applicant to determine the Applicant's preferred approach for development at Point Thomson (ExxonMobil 2009). In developing its proposal for project development, the Applicant evaluated the fabrication, transportation, logistics, and installation of housing, process, and utility modules and equipment. Of the options and components evaluated, the Applicant determined that the combination of landing sealift barges with 11 large modules at Point Thomson and trucking smaller modules via ice road to Point Thomson was the preferred approach for mobilization and development. Using sealift barges allows the Applicant to maximize the size of modules prefabricated offsite and to complete delivery, installation, and commissioning of the modules within a 60-day window in the third year of construction. Large modules would be transported the short distance from the sealift facility to their installation location on the Central Pad via self-propelled modular transporters (SPMTs). Other construction equipment and materials, including fuel, will be transported via coastal barge from Deadhorse.

Alternatives C and D incorporate alternatives to the construction of barge offloading facilities and to the use of barges to transport modules infrastructure, construction equipment, and supplies to the Point Thomson site. Alternative C replaces the use of barging with the construction of a 44-mile long, all-season gravel access road. The construction of the all-season gravel road would occur concurrently with construction of infrastructure at the Point Thomson site. Thus, the gravel road would not be available for use during the construction phase of the project. Alternative D relies on annually constructed and seasonally available ice roads to provide access to the Point Thomson site.

The absence of barging in Alternatives C and D would require more complex logistics and construction sequencing, would pose technological challenges, and would result in a later start up of project facilities, as compared to the Applicant's proposed project. The differing constraints of using ground transportation instead of transportation by sealift barge directly affects the size and number of prefabricated modules

needed for project development, the timing of materials resupply, and the quantity of resupply materials needed during the seasonal ice road window.

Moving prefabricated modules overland from Deadhorse to Point Thomson imposes limits on the size and weight of the infrastructure modules. While gravel roads in the Deadhorse area have been specially designed for heavy transports and can bear loads up to 5,400 tons, ice roads are only capable of bearing loads of up to 1,300 tons, a value based on industry experience from ConocoPhillips Alaska's Alpine development (ExxonMobil 2011c). As a result, prefabricated modules used in Alternatives C and D would need to be smaller to be transported overland via ice road. Consequently they would also need to be more numerous to make up for the decrease in size, resulting in the need for about 32 modules in Alternatives C and D as opposed to the 11 planned for Alternative B (ExxonMobil 2011c). The change in module size and number would require the redesign and reengineering of the modules, which would result in a later start of construction by about two years (ExxonMobil 2011c). The increased number of modules would also require additional staff and would increase the time and manhours needed for assembly and commissioning following the delivery of the modules to Point Thomson (ExxonMobil 2011c).

In addition to altering the size and number of modules, the timing of module delivery would also be impacted. Modules would still be transported to the North Slope from production facilities worldwide by sealift barge during the summer barging season. Modules would be delivered to the West Dock near Deadhorse and would require storage in the Deadhorse area until an ice road is constructed to Point Thomson the following winter season. This results in a delay of module installation of approximately 8 months. The transport of large modules to the West Dock and the movement and storage of the modules in the Deadhorse area is likely to require Deadhorse facility upgrades and the possible construction of additional storage areas in the Deadhorse area.

The movement of large modules from Deadhorse to Point Thomson via ice road also poses technological challenges. While SPMTs are commonly used for movements over short distances and during summer conditions, industry experience moving SPMT loads during the winter is more limited. The Alpine development project provides industry experience with the use of SMPTs for winter transportation in Alaska, highlighting several potential technological issues with winter module movement (ExxonMobil 2011c). SPMTs rely on hydraulics and computers to keep the load balanced. These systems do not function well in cold winter conditions on the North Slope. The operators at Alpine found that the whole hydraulic system needed to be covered with a skirt and continuously heated to prevent the hydraulic fluid from freezing. In addition, the use of lighter hydraulic fluid, which is less susceptible to freezing, caused additional issues with broken linkages on the steering of the SPMT (ExxonMobil 2011c).

Another potential concern with winter module transport is ice road failure, which if it occurs in one location, can trigger a failure of a large area of the road surface as the SPMT computers transfer the weight of the load to other wheels. Road failure could cause the whole transport to become stuck until the road can be repaired. To prevent this issue, SPMT transports require personnel to walk alongside the transporter for the entire length of the trip to monitor the transport and the road surface. While walking alongside the transporter is common in summer months, the sub-zero temperatures of winters on the North Slope add additional personnel safety concerns and would necessitate a traveling caravan of support personnel and vehicles to move with each SMPT along the entire route (HDR 2011c).

At this point in time, modules of the size proposed for Alternatives C and D have not been moved in winter conditions over an ice road of the proposed length. The total length of module movement for the

Alpine development was about 34 miles. The Point Thomson project would require a trip of approximately 49 miles for Alternative C and 47 miles for Alternative D. Even under ideal summer conditions SMPTs move slowly, generally at a maximum speed of 3 mph (ExxonMobil 2011c).The Applicant estimates that that under ideal winter conditions and with no transporter breakdowns, it would take about 48 hours to move a single module one way to Point Thomson. Module transport via ice road would require the construction of a carefully engineered, heavy-duty ice road that would not exceed a 3 percent grade anywhere along its length. The slow moving SPMT caravans would monopolize traffic on the main ice road, requiring the Applicant to construct ice road tie-ins to the pipeline construction ice road to allow fuel and other materials transport vehicles to move around the slow-moving SPMTs.

The absence of barging in Alternatives C and D also alters the transportation of other supplies and materials to the Point Thomson site. The lack of coastal barge access requires all bulk materials, including diesel fuel and construction equipment, be moved to the site during the available ice road season. This would necessitate the movement of a year's worth of fuel to the Point Thomson site between the months of January and April. In addition to the initial fuel storage needs of 1.5 million gallons of diesel described in Section 2.3.1 for all alternatives, Alternative C and D would require an estimated additional 6 million gallons of diesel fuel to support construction activities between the end of the ice road season in the second and third years of construction. Moving this fuel would require about 3,450 fuel truck trips over the course of construction (ExxonMobil 2011c). In contrast, Alternative B would require the storage of just 2.4 million gallons of diesel fuel and would require approximately 880 fuel truck trips during construction because resupplies of fuel would be barged in during the summer barging season (ExxonMobil 2011c). As a single coastal barge has the capacity to carry as much fuel as 10 fuel trucks (ExxonMobil, 2011c). The absence of barging in Alternatives C and D would also increase the total number of helicopter and fixed wing aircraft flights needed to transport materials to Point Thomson.

As discussed in Section 2.3.3, Alternative C replaces barge access to the Point Thomson Site with ground access via an all-season gravel access road. The construction of the 44-mile all season gravel road between the Point Thomson facility and the Endicott Spur road introduces logistical challenges during construction but ultimately would provide reliable year-round, ground access to the site, resulting in long-term logistical benefits to the project. The all-season gravel road would require five additional mine sites and an independent crew of construction workers to complete the project simultaneously with facility construction. The road would likely take at least three years to construct, making it unavailable for module or fuel transport during the construction of the rest of the Point Thomson facility. The gravel road would come online for transportation of personnel and materials during the drilling and operations phases, allowing for year-round ground transportation to the site during these phases.

Alternative D, on the other hand, utilizes annually constructed, seasonal ice roads to provide access to Point Thomson. Having seasonally limited ground access (e.g., seasonal ice road, tundra travel, and air) to the site during drilling and operations greatly limits the transportation and logistical options for the life of the project.

2.4.2.2 Minimization of Coastal Infrastructure

Based on comments received during the EIS Scoping process, the Corps and Cooperating Agencies sought to develop project designs and component alternatives that minimized coastal infrastructure. Alternative C and D include the separation of the Central Well Pad and the Central Processing Facilities, a setback on the East and West Pads one-half mile from the coastline, and a setback of the export pipeline from the coastline.

The setback of the East and West Drilling Pads has the potential to pose technological challenges in the development of the Point Thomson Project. Under any development scenario, the current known characteristics and uncertainties associated with the Thomson Sands reservoir and the challenges of drilling wells in a high-pressure reservoir add technological risks to the project relative to many other hydrocarbon development projects on the North Slope. If completed, the Point Thomson would be the highest pressure, hydrocarbon production field in Alaska and among the highest in the world (White 2011).

The range of locations of drilling sites that can be used to effectively access the Thomson Sand reservoir is constrained by the limitations of the LRD drilling technology. Offshore development, which would provide the largest degree of access to the reservoir (ExxonMobil 2009), was eliminated from consideration as part of the range of reasonable alternatives because of concerns about additional environmental risks and a lack of regulatory and permitting precedence for offshore development on the North Slope (see Section 2.2.2, Viability Analysis). Furthermore, it was established that LRD drilling would allow the Applicant to access a majority of the reservoir from onshore pads.

Based on currently available public information, however, it is not possible to determine how far inland the drilling pads may be moved while still allowing sufficient access to the reservoir to fully delineate and develop the hydrocarbon resources of the Thomson Sands. The proposed project is, in part, intended to provide additional reservoir information in support of a more comprehensive development plan. Current LRD drilling technology in reservoir conditions similar to those found in the Thomson Sands reservoir has a proven horizontal reach of approximately 10,000 to 13,000 feet (Appendix D, RFI 63 of the Draft EIS). Based on proprietary information not currently available to the Corps, the Applicant has determined that the drilling reach from the proposed pads in Alternatives B and E would provide adequate access to drilling targets and would be sufficient to fully delineate and develop the Thomson Sands reservoir (Appendix D, Technical Brief 1 of the Draft EIS).

For the purposes of this analysis, a rough estimate of reservoir coverage in two dimensions was developed using the assumption that the Applicant could achieve a 13,000 ft horizontal drilling reach and that the reservoir is homogeneous. Under these very basic assumptions, drilling from the pads proposed in Alternatives B and E would allow access to approximately 88 percent of the reservoir. Based on the same assumptions, drilling from the East and West pads proposed in Alternatives C and D, located one-half mile inland from the coast, would provide access to approximately 79 percent of the reservoir. It is not known if this coverage would be sufficient to fully develop the hydrocarbon resources in the Thomson Sands reservoir. The Applicant has stated that the "set back of the East and West Pads from the coast one-half mile is not optimal to fully evaluate and develop the Thomson Sand Reservoir" (ExxonMobil 2011c) but the Corps is currently unable to independently verify this statement or determine if this setback would still allow the project to meet the overall purpose. Moving the drilling pads inland may increase the risk that additional drilling pads would be necessary for full-field access and future development.

2.4.2.3 Minimization of Gravel Infrastructure

During the Draft EIS alternative development process, the Corps and Cooperating Agencies also sought to develop an alternative that allowed for the minimization of impacts on wetlands within the project area. Alternative E incorporates these project components, including the use of seasonal, infield ice roads to provide access to the East and West Pads, the use of multi-season ice pads to provide additional acreage at the East and West Pads during the drilling phase, and the use of a shorter airstrip than that planned for

Alternative B. Each of these project components has the potential to influence the project schedule and execution.

Infield Ice Road Infrastructure

The minimization of gravel infrastructure through the use of infield ice roads instead of gravel roads to provide access to the East and West Pads has the potential to reduce the acreage of gravel fill by about 55 acres. The use of ice roads as an alternative to gravel infield roads limits ground access to the East and West Pads to the three months in which ice roads are available for use.

The timeframe for drilling into hydrocarbon bearing formations would be limited under all action alternatives by the terms and conditions of the Applicant's Oil Discharge Prevention and Contingency Plan (ODPCP); the ODPCP, in accordance with 18 ACC 75.445(f) limits drilling in hydrocarbon bearing formations to the period between November 1 through April 15, as planned spill response methods are less effective outside of this period when there is a risk of oil reaching open tundra (Appendix U of the Draft EIS). The seasonal drilling restriction would be included as part of the ODPCP for all action alternatives, but is of particular importance in Alternative E because the seasonal drilling restriction, when combined with the seasonal restrictions on rig movement, would result in a shortened drilling season. The use of seasonal ice roads limits movement of the drill rig to the short period of time when the rig-ready ice roads are available, usually between late January and late April. The combination of these two seasonal constraints could result in the rig being stranded and sitting idle on a pad from late April to the following January when an ice road is available to move the rig to its next target. This stranding could result in the loss of three months of the winter drilling season during November, December, and January, because the rig is unable to be moved to its next target.

Limitations to movement due to the use of seasonal ice roads instead of gravel roads also have impacts on the transportation of construction and drilling materials and personnel. The drilling program relies on the movement of bulk materials, including drilling muds, chemicals, and fuel between the East and West pads and the Central Pad, where most storage occurs. As material movement via ice road would be limited, additional storage space would be needed at the East and West pads and the use of rolligons and other tundra travel vehicles would likely increase relative to the other alternatives.

The limited period of infield ice road transportation would also require extensive helicopter support. Alternative E may require as many as 8,000 trips for construction and drilling and an additional 730 annual trips for operations. These trips would be used to move crew and materials out to the site when the ice road is not available. They could be particularly important in the event of an emergency, such as a medical evacuation or spill response, because helicopters will be the only method of accessing the East and West pads for most of the year. Helicopter access is not always reliable, however; based on experience gained during the exploratory phase of the project, the Applicant estimates that helicopters will be grounded 20 percent of the time due to weather concerns (ExxonMobil 2011c).

Multi-season Ice Pads

The design and construction of the multi-season insulated ice pad extensions at the East and West Pads would allow restoration of vegetation communities beneath those structures to begin to occur shortly after the completion of drilling. However, the lack of prior experience building multi-season pads of the type required results in technological uncertainties. Single season ice pads are a relatively common construction tool used on the North Slope but the use of multi-season ice pads has been more limited. Multi-season ice pads have been used in the past for two projects on the North Slope, one for an

exploration well in Umiat and another for BP's Yukon Gold (Ragsdale 2007). The ice pads constructed for the 1993 Yukon Gold exploratory project were 2.5 acres in size, six inches of ice thick with insulation board on top, and designed to last two winter drilling seasons (ExxonMobil 2011c).

In contrast, the Alternative E multi-season ice pads would be about 11 acres in size, 6 feet of ice thick, and overlain by rigmats. The pads would be designed to last for the entire five-year duration of the drilling program. There is currently no prior experience on the North Slope that can inform the technological feasibility of the construction, maintenance, and operation of an ice pad of the required size and thickness. In addition to the estimated 3.4 million gallons of water needed to build the ice pads, additional water will be needed each year for ice pad maintenance. Over the course of the summer, each of the ice pad extensions would likely lose between 8 to 10 feet around each exposed edge due to melting and would require maintenance work in early winter to recover the area before drilling could begin. The construction, maintenance, and performance of the multi-season ice pads pose technological uncertainties in the implementation of Alternative E.

Shortened Airstrip

The shorter gravel airstrip (3,700 by 200 ft) included in Alternative E would reduce the acreage of gravel fill by 14 acres relative to Alternative B, but may also have an impact on the number of material and personnel flights needed outside of the barging and ice road seasons. The Applicant estimates that the shorter airstrip would limit the size of aircraft capable of landing at Point Thomson to those with a capacity of 5,000 lbs or 15 people or less as compared to the average capacity of planes capable of landing on the longer airstrips in Alternatives C, D, and E (~ 24,000 lbs or 30 people). The effect of shortening the airstrip would be to double the number of flights needed during construction, drilling, and operations. In addition, the airstrip would not be capable of accommodating a C-130 craft (capacity of 45,000 lbs), which the Applicant has proposed for use in case of emergency. This may result in alterations to the Applicant's emergency response capability (ExxonMobil 2011c).

2.5 PRACTICABILITY SUMMARY

Based on the practicability information and environmental considerations discussed above, sufficient information is not yet available to determine if the Applicant's proposed project is the LEDPA, or if alternatives with less impact to the aquatic ecosystem have other significant adverse environmental consequences. As discussed in Section 2.2, Alternatives Development, the Corps believes that it has captured all of the reasonable alternatives and components necessary to determine whether the Applicant's proposed project is the LEDPA. However, information on the cost of project alternatives and alternative components will be a crucial aspect in the Corps' final determination of practicability, information that must be provided by the Applicant before this evaluation can be completed.

Preliminary consideration of all four Draft EIS action alternatives reveals that each alternative contains drawbacks and benefits with respect to technology, logistics, and the potential for environmental impacts. The incorporation of alternative components into Draft EIS Alternatives C, D, and E has varying effects on the logistics, technology, and schedule of the plan for development of the Point Thomson Project. However, these tradeoffs do not necessarily result in Alternatives C, D, and E being not practicable. At this point in time, the Corps considers all Draft EIS alternatives and alternative components to be practicable.

The Corps seeks public comment on the determination of practicability and invites the public to provide input regarding the evaluation of the Point Thomson project under the Guidelines.

3. Restrictions on Discharge (40 CFR 230.10(b))

The second compliance test under the Guidelines considers specific impacts that may warrant additional restrictions on discharge. Specifically, the Guidelines state that no discharge of dredged or fill material may be permitted if it will:

1) Causes or contribute to violations of any applicable State water quality standard;
2) Violate any applicable toxic effluent standard or prohibition under Section 307 of the CWA;
3) Jeopardize the continued existence of species listed as endangered or threatened under the ESA of 1973, or result in the potential for adverse impacts (destruction or adverse modification) of a habitat which is determined by the Secretary of the Interior or Commerce to be a critical habitat under the ESA of 1973. If an exemption has been granted by the Endangered Species Committee, the terms of the exemption shall apply, in lieu of this paragraph; or
4) Violate any requirement imposed by the Secretary of Commerce to protect any marine sanctuary designated under title III of the Marine Protection, Research, and Sanctuaries Act of 1972.

If the proposed discharge is found to violate the standards or cause any of the adverse impacts listed above, the discharge may not be permitted.

The Corps has not yet made a determination regarding the compliance of the Applicant's proposed project with the restrictions on discharge test of the Guidelines. A determination of whether the proposed project meets the standards listed above will ultimately be based on the findings outlined in Appendix A, Factual Determinations, and Appendix B, Technical Evaluation Factors.

The Corps invites the public to review the analysis of impacts found in the Draft EIS and incorporated by reference into the Factual Determinations and Technical Evaluation Factors (Appendices A and B). The Corps seeks public comment on the evaluation of the compliance or non-compliance of the Applicant's proposed project with the restrictions on discharge listed above.

4. Finding of No Significant Degradation (40 CFR 230.10 (c))

The third compliance test under the Guidelines considers the potential for the proposed discharge to cause or contribute to the degradation of waters of the U.S. The Guidelines state that except as provided under Section 404(b)(2), the discharge of dredged or fill material that will cause or contribute to significant degradation of waters of the U.S. may not be permitted. The Guidelines further define the types of effects that may, either individually or collectively, contribute to the significant degradation of waters of the U.S. These include:

1) Significant adverse effects of discharge of pollutants on human health or welfare, through pollution of municipal water supplies, fish, shellfish, wildlife and special aquatic sites;

2) Significant adverse effects of discharge of pollutants on life stages of aquatic wildlife and other wildlife dependent on aquatic ecosystems, to include the transfer, concentration, and spread of pollutants or their byproducts outside of the disposal site through biological, physical, and/or chemical processes;

3) Significant adverse effects of discharge of pollutants on aquatic ecosystem diversity, productivity, and stability including but not limited to the loss of fish and wildlife habitat, or the loss of the capacity of wetland to assimilate nutrients, purify water, or reduce wave energy; and

4) Significant adverse effects of discharge of pollutants on recreational, aesthetic, and/or economic values.

At this time, the Corps has not yet made a determination of the compliance of the Applicant's proposed project with the test of no significant degradation. The determination of whether the Applicant's proposed project causes or contributes to significant degradation of waters of the U.S. will ultimately be based on the conclusions of the Factual Determinations (Appendix A) and the Evaluation of Dredged or Fill Material (Appendix B, Section 5). The conclusions of these two Appendices also take into account the detailed analysis of impacts on specific physical, chemical, biological and human characteristics of the aquatic ecosystem found in the Technical Evaluation Factors (Appendix B, Sections 1 though 4). The determination of compliance will also take into consideration Actions to Minimize Adverse Effects, found in Appendix C.

The Corps invites the public to review the analysis of impacts found in the Draft EIS and incorporated by reference into the Factual Determinations, Technical Evaluation Factors, and Actions to Minimize Adverse Effects in this document (Appendices A, B, and C). The Corps seeks public comment on the evaluation of the compliance or non-compliance of the Applicant's proposed project with the standards of no significant degradation outlined above.

5. Minimization of Potential Adverse Impacts (40 CFR 230.10(d))

The fourth compliance test under the Guidelines considers the extent to which steps have been taken to minimize potential adverse effects. The Guidelines state that except as provided under Section 404(b)(2), no discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken which will minimize potential adverse impacts of the discharge on the aquatic ecosystem.

At this time, the Corps has not yet made a determination of the compliance of the Applicant's proposed project with the test of minimization of potential adverse impacts. This determination, however, will ultimately be based on the minimization measures identified in Subpart H, Actions to Minimize Adverse Effects (Appendix C).

The Applicant has already identified several potential measures to minimize adverse impacts. These measures are outlined in the Applicant's Environmental Mitigation Report (ExxonMobil 2011d) and Final Department of the Army Permit Application (ExxonMobil 2011a). These measures are also discussed in detail in Section 4.4, Impact Avoidance, Minimization, and Mitigation, in the Draft EIS and by resource section in Chapter 5, Environmental Consequences, of the Draft EIS.

The Corps has reviewed the minimization measures proposed by the Applicant and considers them to be a reasonable starting point for developing the list of all appropriate and practicable steps which can be taken to minimize the potential adverse impacts of the proposed project. However, the Corps has not yet determined if the Applicant's proposed minimization actions include all appropriate and practicable measures. The Corps invites the public to comment on the current list of Applicant proposed minimization measures and to provide suggestions on additional avoidance and minimization measures that may be appropriate and practicable which will help reduce impacts to waters of the U.S. and aquatic ecosystems. A list of common minimization measures is provided in Appendix C.

6. Summary of Findings of Compliance

This document constitutes a draft of the Corps' evaluation of compliance with the Guidelines. This chapter will ultimately contain the Corps' findings of compliance based on Chapter 2, Finding of Practicable Alternatives (40 CFR 230.10 (a)); Chapter 3, Restrictions on Discharge (40 CFR 230.10 (b)); Chapter 4, Finding of No Significant Degradation (40 CFR 230.10 (c)); and Chapter 5, Minimization of Potential Adverse Effects (40 CFR 230.10 (d)).

As discussed in Chapter 1, however, the Corps will not finalize its compliance determination regarding the Applicant's permit application until after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS. At that time, the Corps will issue a ROD describing its decision on the permit application and its determination of whether the Applicant's proposed project complies with the Guidelines.

Appendix A:

Factual Determinations (40 CFR 230.11)

Construction of the Applicant's proposed project would include the discharge of dredged or fill material in wetland and waters of the U.S. The Guidelines (40 CFR 230.11, Subpart B) require determination of the potential short-term and long-term effects of the proposed discharges of dredged or fill material on the physical, chemical, and biological components of the aquatic environment. These factual determinations will determine if there is minimal potential for shot-term or long-term significant adverse environmental effects of the proposed discharge. The determinations will be made in Sections 1 through 8 below, based on the findings of Subparts C through F (Appendix B, Technical Evaluation Factors).

1. Physical Substrate Determinations (40 CFR 230.11 (a))

Physical substrate determinations include an evaluation of effect that the proposed discharge will have, individually and cumulatively, on the substrate at the proposed disposal site. Considerations include the similarity in particle size, shape, and degree of compaction of the material proposed for discharge and the material constituting the substrate at the disposal site, and any potential changes in substrate elevation and bottom contours, including changes outside of the disposal site which may occur as a result of erosion, slumpage, or other movement of the discharged material. The duration and physical extent of substrate changes is also considered. Potential changes in substrate elevation and bottom contours are predicted on the basis of the proposed method, volume, location, and rate of discharge, as well as on the individual and combined effects of current patterns, water circulation, wind and wave action, and other physical factors that may affect the movement of the discharged material.

Sections 3.1, Geology and Geomorphology and 3.2, Soils and Permafrost of the Draft EIS describe the existing substrate under the proposed disposal site within the project area. A determination of impacts on the physical substrate for the Guidelines evaluation will be based on impact analysis included in the Section 5.2, Soils and Permafrost of the Draft EIS, the Technical Evaluation Factors findings of Subpart C (Appendix B, Section 1), and the Actions to Minimizing Adverse Effects found in Subpart H (Appendix C).

2. Water Circulation, Fluctuation, and Salinity Determinations (40 CFR 230.11 (b))

Water circulation, fluctuation, and salinity determinations include evaluation of the nature and degree of effect that the proposed discharge will have individually and cumulatively on water, current patterns, circulation including downstream flows, and normal water fluctuation. Consideration is given to water chemistry, salinity, clarity, color, odor, taste, dissolved gas levels, temperature, nutrients, eutrophication, and any other appropriate characteristics. Consideration is also given to the potential diversion or obstruction of flow, alterations of bottom contours, or other significant changes in the hydrologic regime. Potential impacts on the current patterns, water circulation, normal water fluctuation, and salinity are evaluated on the basis of the proposed method, volume, location, and rate of discharge.

Sections 3.5, Physical Oceanography and Coastal Processes and 3.6, Hydrology of the Draft EIS describe the existing freshwater hydrology and coastal water circulation, including streams, lakes, and nearshore lagoons and basins in the project area. Information regarding the impacts of the proposed Point Thomson Project activities on current patterns and water circulation in the project area may be found in Sections 5.5, Physical Oceanography and Coastal Processes; 5.6, Hydrology; and 5.7, Water Quality of the Draft

EIS. A determination of impacts on water circulation, fluctuation, and salinity will be based on the Technical Evaluation Factors findings in Subpart C as part of Appendix B, Sections 1.3, Water Quality and Chemistry, 1.4, Water Circulation and Current Patterns, 1.5 Normal Water Fluctuations, and.1.6, Salinity Gradients and on the proposed actions for minimizing effects found in Subpart H (Appendix C). The evaluation of impacts will also be based on the analysis of impacts in the Draft EIS.

3. Suspended Particulates and Turbidity Determinations (40 CFR 230.11 (c))

Suspended particulates and turbidity determinations include an evaluation of the nature and degree of effect that the proposed discharge will have on the kinds and concentrations of suspended particulates and turbidity in the vicinity of the disposal site. Consideration is given to the grain size of the material proposed for discharge, the shape and size of the plume of suspended particulates, the duration of the discharge and resulting plume, and whether or not the potential changes will cause violations of applicable water quality standards. Considerations include the proposed method, volume, location, and rate of discharge, as well as the individual and combined effects of current patterns, water circulation and fluctuations, wind and wave action, and other physical factors on the movement of suspended particulates.

Sections 3.5, Physical Oceanography and Coastal Processes; 3.6, Hydrology; and 3.7 Water Quality of the Draft EIS describe existing characteristics of water quality, including suspended particulates and turbidity in both marine and freshwater in the project area. A determination of impacts on suspended particulates and turbidity will be based on the impact analysis found in Sections 5.5, Physical Oceanography and Coastal Processes; 5.6, Hydrology; and 5.7, Water Quality of the Draft EIS, the Technical Evaluation Factors findings in Subpart C as part of Appendix B, Sections 1.2, Suspended Particulates and Turbidity, and the Actions for Minimizing Adverse Effects found in Subpart H (Appendix C).

4. Contaminant Determinations (40 CFR 230.11 (d))

The factual determinations within the Guidelines require a determination of the degree to which the material proposed for discharge could introduce, relocate, or increase contaminants. This determination considers the material to be discharged, the aquatic environment at the proposed disposal site, and the availability of contaminants.

Sections 3.2, Soils and Permafrost and 3.24, Contaminated Sites and Spill History of the Draft EIS provide information regarding the character of the materials proposed for discharge and the potential for contamination in discharge material in the project area. The determination of the potential for contaminants will be based on the analysis of impacts in Sections 5.2, Soils and Permafrost and 5.24, Spill Risk and Impact Assessment of the Draft EIS, and on the evaluation of dredged and fill materials conducted as part of the Evaluation of Dredged or Fill Material in Subpart G (Appendix B, Section 5) of this document.

5. Aquatic Ecosystems Structure and Function Determinations (40 CFR 230.11 (e))

The determination of impacts on the structure and function of aquatic ecosystems includes an evaluation of potential changes in substrate characteristics and elevation, water or substrate chemistry, nutrients, currents, circulation, fluctuation, and salinity on the existence or recolonization of indigenous aquatic organisms or communities.

The aquatic ecosystems of the Point Thomson area include both freshwater and marine habitats. These ecosystems support wetland vegetation, fish, invertebrate, bird, and marine mammal populations. A determination of impacts on the structure and function of the aquatic ecosystem will be based on the impact analysis found with in Sections 5.8, Vegetation and Wetlands; 5.9, Birds; 5.11, Marine Mammals; and 5.12, Fish, Essential Fish Habitat, and Invertebrates of the Draft EIS, the Technical Evaluation Factors findings in Subparts D and E as part of Appendix B, Sections 3.2, Wetlands, 2.2, Aquatic Food Web, and 2.3, Other Wildlife, and the Actions for Minimizing Adverse Effects found in Subpart H (Appendix C). In addition, Appendix J, Mapped Land Cover of the Draft EIS, and Appendix K, Wetland Functional Assessment of the Draft EIS provide supporting information on vegetation classification and function assessment. This factual determination may also include information based on the Subpart G: Evaluation of the Dredged or Fill Material (Appendix B, Section 5) to evaluate the effect the discharge may have on communities or populations of organisms expected to be exposed to it.

6. Proposed Disposal Site Determination (40 CFR 230.11 (f))

The proposed disposal sites for dredged and fill materials are described in detail in Section 2.3, Alternatives Descriptions of the Draft EIS and the Applicant's Final Department of the Army Permit Application (ExxonMobil 2011a). As part of the Applicant's proposed project, fill materials would be placed for the construction of project components and facilities including gravel infrastructure for roads, pads, and airstrips; gravel infrastructure for export and gathering pipeline supports; bridges and culverts associated with the gravel roads, and the emergency boat ramp facility. In addition to these project components, the proposed project would also include the placement of fill for the construction of the barge offloading facilities and the disposal of dredged materials from the barge offloading area. The location of the proposed disposal sites for all action alternatives can be seen in Figures 2.4-5 and 2.4-6 of the Draft EIS.

The Guidelines state that the mixing zone associated with each specified disposal site shall be confined to the smallest practicable area consistent with the type of discharge dispersion being used. As part of this determination, the Corps' must evaluate the acceptability of the proposed disposal sites and mixing zone based on the following factors:

- Depth of water at the disposal site;
- Current velocity, direction, and variability at the disposal sites;
- Degree of turbulence;
- Stratification resulting from causes such as obstructions or salinity or density profiles at the disposal site;
- Discharge vessel speed and direction if appropriate;
- Rate of discharge;
- Ambient concentration of constituents of interest;
- Dredged material characteristics, including concentrations of constituents, amount of material, type of material, and settling velocities;
- Number of discharge actions per unit time; and
- Other factors of the disposal site that affect the rates and patterns of mixing.

Sections 3.2, Soils and Permafrost; 3.5, Physical Oceanography and Coastal Processes; 3.6, Hydrology; and 3.24, Contaminated Sites and Spill History, of the Draft EIS provide information regarding existing

conditions at the proposed disposal site. The factual determination of the proposed disposal site will be based on the impact analysis found in Sections 5.2, Soils and Permafrost; 5.5, Physical Oceanography and Coastal Processes; 5.6, Hydrology; and 5.24, Spill Risk and Impact Assessment of the Draft EIS. The factual determination will also be based on the findings of Subparts C (Appendix B, Section 1) and H (Appendix B, Section 5) of this document.

7. Determination of Cumulative Effects on the Aquatic Ecosystem (40 CFR 230.11 (g))

Cumulative impacts are the changes in an aquatic ecosystem that are attributable to the collective effect of a number of individual discharges of dredged or fill material. Although the impact of a particular discharge may constitute a minor change in itself, the cumulative effect of numerous such piecemeal changes can result in a major impairment of the water resources and interfere with the productivity and water quality of existing aquatic ecosystems. A determination of cumulative impacts that may result from the discharge of dredged or fill material in waters of the U.S. should be evaluated to the extent reasonable and practical.

Past and present actions in the project area that have affected the aquatic ecosystem in the project area include oil and gas exploration and development, roads, community development, military infrastructure, scientific research, and the release of air pollutants worldwide that has resulted in deposition of pollutants on Alaska's North Slope. Reasonably foreseeable future actions include additional oil and gas developments including the full field development at Point Thomson and the construction of a gas export pipeline; additional transportation infrastructure such as the proposed Foothills West Road; and continued use of the area for tourism, recreation, subsistence uses, and scientific research. See Section 4.2, Cumulative Impacts Methodology of the Draft EIS for a full list of past and present actions in the project area.

Sections 5.8, Vegetation and Wetlands; 5.9, Birds; 5.11, Marine Mammals; and 5.12, Fish, Essential Fish Habitat, and Invertebrates of the Draft EIS contain detailed analysis of potential cumulative impacts to the aquatic ecosystem from past, present, and reasonably foreseeable future actions that could result under all Draft EIS alternatives. The determination of cumulative effects on the aquatic ecosystem will be based on these Draft EIS impact analyses with consideration for impacts discussed in the Technical Evaluation Factors in Subparts D (Appendix B, Section 2) and E (Appendix B, Section 3) of this document.

8. Determination of Secondary Effects on the Aquatic Ecosystem (40 CFR 230.11 (h))

Secondary effects are effects on an aquatic ecosystem that are associated with a discharge of dredged or fill materials, but do not result from the actual placement of the dredged or fill material. For the proposed Point Thomson Project, a consideration of secondary effects may include the potential for a spill of hydrocarbon or other toxic materials; impacts to wetlands, vegetation, and water bodies as a result of dust, snow buildup, impoundments and thermokarst effects; the disturbance of wildlife populations as a result of noise or human activity; and a change in wildlife survival or productivity.

Sections 5.8, Vegetation and Wetlands; 5.9, Birds; 5.11, Marine Mammals; 5.12, Fish, Essential Fish Habitat, and Invertebrates; and 5.24, Spill Risk and Impact Assessment of the Draft EIS contain detailed analysis of potential secondary impacts to the aquatic ecosystem. The factual determination of secondary effects will be based on these impact analyses and on the analyses found in Subparts D (Appendix B, Section 2) and E (Appendix B, Section 3) of this document.

Appendix B:

Technical Evaluation Factors

The technical evaluation factors discussed in this appendix evaluate potential impacts on the physical and chemical characteristics of the aquatic ecosystem (Subpart C), biological characteristics of the aquatic ecosystem (Subpart D), special aquatic sites (Subpart E), and human use characteristics (Subpart F). Subpart G discusses the evaluation of the proposed fill material.

1. Subpart C: Potential Impacts on Physical and Chemical Characteristics of the Aquatic Environment

1.1. Substrate (40 CFR 230.20)

The substrate of the aquatic ecosystem underlies open waters of the U.S. and constitutes the surface of wetlands. It consists of organic and inorganic solid materials and includes water and other liquids or gases that fill the spaces between solid particles. Sections 3.1, Geology and Geomorphology and 3.2, Soils and Permafrost of the Draft EIS describe existing characteristics of the substrate within the project area.

The physical substrate on which the proposed fill would be placed primarily consists of an upper layer of organic peat and/or organic silt overlying massive ice, sand, and gravel layers. Permafrost extends from depths of 650 to 2,100 feet below the land surface and is essential for the development of microgeographical features on the ACP. Increases in permafrost thickness and extent are driven by climatic cooling, maturation of vegetation, increased albedo, and decreased snow cover. Climatic warming, removal or compaction of vegetation, and mass wasting will decrease the thickness or extent of the permafrost. The near-surface soils subject to seasonal thaw are referred to as the active layer.

Climate is the dominant soil-forming factor in the ACP. The underlying permafrost creates an impermeable barrier that influences surface morphology and hydrology through the waterlogging of surface soils. The cold climate inhibits certain soil-forming processes such as weathering and movement of clay downward through the soil, while organic matter accumulation is heightened due to the reducing conditions caused by saturation, slowed decomposition in the cold, wet conditions, and churning of the surface organic materials to the lowest parts of the active layer and upper permafrost.

1.1.1. Potential Impacts

The analysis of impacts to the physical substrate may include consideration of potential changes in the complex physical, chemical, and biological characteristics of the substrate. Discharges which alter substrate elevation or contours can result in changes in water circulation, depth, current pattern, water fluctuation, and water temperature. Discharges may adversely affect bottom-dwelling organisms at the site by smothering stationary organisms or forcing mobile organisms to migrate. Benthic forms present prior to a discharge are unlikely to recolonize the area around discharged material if it is too dissimilar from that of the discharge site.

Other potential impacts that will be evaluated include the erosion, slumping, or lateral displacement of dredged and fill material that can adversely affect areas of the substrate outside the perimeters of the disposal site by changing or destroying habitat. The bulk and composition of the discharged material and the location, method, and timing of discharges may all influence the degree of impact on the substrate.

Information regarding the impacts of each alternative on the physical substrate of the project area may be found in Section 5.2, Soils and Permafrost of the Draft EIS. Impact analysis from the Draft EIS will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

1.2. Suspended Particulates and Turbidity (40 CFR 230.21)

Turbidity is cloudiness caused by fine grained, mineral particles of solid matter suspended in water. It is measured by the amount of scattering and absorption of light rays caused by the particles and is reported in nephelometric turbidity units (NTU; (Brooks, et al. 2003). Total suspended solids (TSS), measured in milligrams per liter (mg/l), is a water quality parameter that refers to the weight of solids suspended in water that can be removed by a filter. Section 3.7, Water Quality of the Draft EIS describes existing characteristics of suspended particles and turbidity in the project area.

In the marine environment of the project area, turbidity and suspended particulates vary seasonally. During spring breakup, turbidity and TSS concentrations are usually at their highest due to runoff from watersheds and peak discharges being able to carry a high sediment load downstream and into the marine environment. Coastal erosion also has a large influence on turbidity values and TSS concentrations throughout the open-water season. During the winter, sea-ice conditions prevent wind from being a factor in stirring up the sediments that could increase turbidity or TSS. While there can be under-ice water movement that occasionally causes bottom sediments to be introduced into the water column, winter turbidity concentrations are lower than values observed in the summer.

Freshwater turbidity in the project area can be affected by many factors, including sediment load, organic matter concentration, maximum particle size the stream discharge can carry, the season, and the amount of plant material in the riparian zone of the streams. The highest turbidity concentrations are typically observed during the spring breakup event when discharge is high and overground runoff occurs. Sediments, plant material, and all other organic materials flushed into the water system are the primary causes of increased turbidity during breakup or high-flow events. The transport of material during breakup is an important part of the hydrologic cycle in the area and can result in the movement of more than 80 percent of the total suspended sediment load for the entire year in Alaskan arctic streams and rivers (Rember and Trefry 2004, Trefry, et al. 2009).

1.2.1. Potential Impacts

The analysis of impacts to suspended particulates and turbidity will include consideration of changes to turbidity, such as elevated levels of suspended particulates in the water column for varying lengths of time. Higher turbidity levels may reduce light penetration and lower the rate of photosynthesis and primary productivity of an aquatic area. Sight dependent species may suffer reduced feeding ability, leading to limited growth and lowered resistance to disease if high levels of suspended particulates persist. The biological and the chemical content of the suspended material may react with the dissolved oxygen in the water, which can cause oxygen depletion. Toxic metals and organics, pathogens, and viruses absorbed or adsorbed to fine-grained particulates in the material may become biologically available to organisms either in the water column or on the substrate. Significant increases in suspended particulate levels create turbid plumes which may be highly visible and aesthetically displeasing. The extent and persistence of these adverse impacts depend upon the relative increase in suspended particulates above the amount occurring naturally, the duration of the higher levels, the current patterns, water level, and fluctuations present when discharges occur. Potential impacts also depend on the volume, rate, and duration of the discharge, particulate deposition, and the seasonal timing of the discharge.

Sections 5.6, Hydrology, and 5.7, Water Quality of the Draft EIS describe the potential impacts of the proposed discharge of dredged and fill materials on suspended particulates and turbidity in the project area. The Draft EIS impact analysis of the proposed discharge on suspended particulates and turbidity will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

1.3. Water Quality and Chemistry (40 CFR 230.22)

Water is the part of the aquatic ecosystem in which organic and inorganic constituents are dissolved and suspended. Characteristics, including clarity, nutrients and chemical content, physical and biological content, dissolved gas level, pH, and temperature, contribute to its life-sustaining capabilities. Sections 3.6, Hydrology and 3.7, Water Quality of the Draft EIS describe the existing freshwater and marine resources and water quality. Water quality, as it relates to turbidity, particulates, and salinity are discussed in Sections 1.2, Suspended Particulates and Turbidity and 1.6, Salinity Gradients.

Marine water quality in the study area is good. Temperature in the Beaufort Sea varies depending on location and time of year. In the project area, temperatures can range from 30°F to 37°F (Craig 1984). Dissolved oxygen (DO) concentrations in the Beaufort Sea and Lions Bay also vary by season, with DO concentrations decreasing during winter months when oxygen and carbon dioxide exchange between atmosphere and water cease due to thick ice conditions. However, depending on ice cover and circulation patterns, DO concentrations remain in a range that is conducive to overwintering for many fish species. Trace metals naturally occur in the Beaufort Sea and are introduced from coastal erosion, freshwater inputs, and atmospheric deposition. No elevated concentrations of trace metals, nitrogen, or hydrocarbons have been detected in water sampled from Lion Bay.

Freshwater quality in the study area is good; no freshwater bodies in the project area are listed as impaired. Water quality parameters, such as DO, biochemical oxygen demand (BOD), pH, nitrogen, organic carbon, and trace metals vary by water body type, size, location, and season of the year, but generally fall within ADEC water quality standards for aquatic life and surface and drinking water.

The seasonal effect of freeze-thaw cycles plays a major role in water quality on the North Slope. Water bodies shallower than 7 feet typically freeze to the bottom during the winter. Water bodies that retain liquid water over the winter may experience changes in water quality in that water as DO concentrations are depleted and the concentration of suspended solids can be 30 times higher than in summer months (Hobbie 1980). Each spring, during peak discharge, snowmelt and high sediment loads can also affect water quality parameters including decreasing alkalinity, lowering DO concentrations, and increasing trace metal concentrations. Similarly, nearly half of the annual total concentration of dissolved organic carbon is transported downstream during peak flows at spring breakup (Rember and Trefry 2004).

1.3.1. Potential Impacts

The analysis of impacts to water quality and chemistry will include consideration of changes in the chemistry and the physical characteristics of water at a disposal site through the introduction of chemicals or changes in the clarity, color, odor, and taste of water and the addition of contaminants. Changes in water quality may reduce or eliminate the suitability of water bodies for populations of aquatic organisms, and for human consumption, recreation, and aesthetics. The introduction of nutrients or organic material to the water column as a result of the discharge can lead to a high BOD, which in turn can lead to reduced DO, thus potentially affecting the survival of many aquatic organisms. Increases in nutrients can favor

one group of organisms such as algae to the detriment of other more desirable types such as submerged aquatic vegetation.

Information regarding the impacts of the proposed project activities of the Draft EIS alternatives on water resources and water quality in the project area may be found in Sections 5.6, Hydrology; and 5.7, Water Quality of the Draft EIS. The Draft EIS impact analysis of the proposed discharge on water quality and chemistry will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

1.4. Water Circulation and Current Patterns (40 CFR 230.23)

Current patterns and water circulation are the physical movement of water in the aquatic ecosystem. Sections 3.5, Physical Oceanography and Coastal Processes; 3.6, Hydrology; and 3.7, Water Quality of the Draft EIS describe existing freshwater and marine circulation and current patterns of the project area.

1.4.1. Marine Environment

In the project area along the Beaufort Sea coast, the circulation of nearshore waters is driven primarily by the wind. In the passes between barrier islands, as well as between barrier islands and the mainland, currents are aligned with the directional axis of the passes and are responsive to the overall action of wind on the lagoons contained between barrier islands and the mainland.

Water circulation and ocean processes continue during winter, when sea ice covers the water column. Sea ice begins to form within Lion Lagoon, and elsewhere along the Beaufort Sea coast, as early as mid-September. Ice movement is more likely earlier in the winter season, before nearshore ice becomes thicker and landfast; however, landfast ice is still subject to both wind and water movement. Within the lagoons along the Beaufort Sea coast, the landfast ice generally extends from the mainland shore to the barrier islands. Wind stress applied to the ice sheet can trigger movement of the sea ice, which in turn can scour shorelines and the seabed. On shorelines that are exposed to the open sea, onshore winds can push the sea ice onto the beach, producing an ice pile up that can reach many meters high and extend inland several tens of meters.

1.4.2. Freshwater Environment

Freshwater circulation in the project area is characterized by three main river drainages, many smaller rivers and streams, numerous thaw lakes, and shallow, seasonal interstitial groundwater. Three major drainages are located in the western portion of the study area: the Sagavanirktok (5,570 square miles [mi^2]), Kadleroshilik (586 mi^2), and Shaviovik (1,555 mi^2) Rivers, all of which have their headwaters outside of the ACP in the Brooks Range. Smaller streams between the Shaviovik and Staines Rivers originate on the Canning River fan and are contained completely within the ACP. Drainage areas of these smaller streams range from 0.2 to 95.6 mi^2.

Thaw lakes (lakes formed when water melts and collects on the ground surface, above an unbroken permafrost layer) occur in abundance across the ACP and are one of the dominant terrain features. Thaw lakes occur more often in the western ACP than in the eastern ACP. The lakes in the project area vary in size and depth, but tend to be shallow with large surface areas. Lakes shallower than 7 feet typically freeze to the bottom during the winter. During spring breakup, snow and ice melt brings lakes and streams back to their natural water levels and inundate the polygonal ground complexes with microlows in the project area. Lake volumes are largely dependent on the size of the drainage basin, runoff characteristics, amounts of precipitation, and amount of evaporation from the water surface.

Shallow seasonal interstitial groundwater occurs in contact with thaw lakes, rivers, and streams. These shallow bodies of groundwater are isolated, and do not form a water table, even seasonally. The permafrost layer serves as a barrier to surface recharge.

1.4.3. Potential Impacts

The analysis of impacts to water circulation and current patterns will include consideration of potential modifications of current patterns and water circulation created by obstructing flow, changing the direction or velocity of water flow and circulation, or changing the dimensions of a water body. Potential impacts may include adverse changes to the location, structure, and dynamics of aquatic communities; shoreline and substrate erosion and deposition rates; the deposition of suspended particulates; the rate and extent of mixing of dissolved and suspended components of the water body; and water stratification. Sections 5.5, Physical Oceanography and Coastal Processes; 5.6, Hydrology; and 5.7 Water Quality of the Draft EIS describe potential impacts of project infrastructure on water circulation and current patterns. The Draft EIS impact analysis of the proposed discharge on water quality and chemistry will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

1.5. Alteration of Normal Fluctuations (40 CFR 230.24)

Normal water fluctuations in a natural aquatic ecosystem consist of daily, seasonal, and annual tidal and flood fluctuations in water level. Sections 3.5, Physical Oceanography and Coastal Processes; 3.6, Hydrology; and 3.7, Water Quality of the Draft EIS describe existing freshwater and marine water fluctuations in the project area. Additional information is provided in Section 1.4, Water Circulation and Current Patterns.

1.5.1. Marine Environment

Marine water level variations along the Beaufort Sea coast are the result of tides, storm surge, and waves. Tides in the area have a mean diurnal range of only 0.7 feet. Storm surges are a far more important cause of water level variation and are the result of strong winds blowing parallel to the coast. Strong easterly winds can produce negative storm surges of as much as 2 to3 feet, while strong westerlies can produce positive storm surges of 4 to 6 feet or even more. Wave heights observed within Lion Lagoon during a 1982 study were mostly less than 2 feet, although occasional storms caused waves as high as 5 feet.

1.5.2. Freshwater Environment

Streamflow on the North Slope follows a seasonal pattern as streams begin to freeze in September, are at or near zero during December or January, and then rapidly release more than half of annual flow during the 1 to 2 week melting window in late May or early June. The rapid release of such a large volume of water during breakup leads to overbank flooding of the shallow drainage network. Large amounts of sheetflow also results from the fact that most streams and rivers that have water in them in September typically freeze to the bottom and become so clogged with ice and snow that they have very little conveyance. Furthermore, the freezing of the active layer of soil in the fall means that most runoff remains above ground instead of being absorbed by the soil.

Breakup begins earliest in the spring in the mountains, and streamflow persists longer in the fall in longer rivers originating in the mountainous provinces (Sloan 1987). Stream discharge is a function of the volume of ice frozen in channels and drainage basin runoff. Streams originating on the ACP, such as smaller streams on the Canning River fan, are not expected to produce large ice floes or ice damming

because these streams are typically dry during late fall and early winter, when the ice would form. Major rivers such as the Sagavanirktok, the Kadleroshilik, and Shaviovik, which often sustain winter baseflows, have higher potential for ice dams and ice debris during spring breakup than smaller streams. While the flooding regime for rivers in this area is dominantly snowmelt-driven, rivers draining the Brooks Range, such as the Sagavanirktok River, also have the potential to produce significant summer precipitation-driven flood discharges

Lake levels in the project area are impacted by evapotranspiration and water withdrawals for human use. Studies of lake recharge following water withdrawal in areas west of Point Thomson found that lakes are able to recharge from spring snow melt. However, the study also suggested that the capacity of water resources to support operations that consume water differs between the regions. No evaluations of lake recharge have been conducted in the project area.

1.5.3. Potential Impacts

The analysis of impacts related to normal water fluctuations will include consideration of changes to the normal water-level fluctuation pattern of an area, resulting in prolonged periods of inundation; exaggerated extremes of high and low water; or a static, non-fluctuating water levels. Such water level modifications may change salinity patterns, alter erosion or sedimentation rates, aggravate water temperature extremes, and upset the nutrient and dissolved oxygen balance of the aquatic ecosystem. In addition, these modifications can alter or destroy communities and populations of aquatic animals and vegetation, induce populations of nuisance organisms, modify habitat, reduce food supplies, restrict movement of aquatic fauna, destroy spawning areas, and change adjacent, upstream, and downstream areas.

Sections 5.5, Physical Oceanography and Coastal Processes; 5.6, Hydrology; and 5.7, Water Quality of the Draft EIS describe potential impacts of project infrastructure on water fluctuations. The Draft EIS impact analysis of the proposed discharge on water quality and chemistry will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

1.6. Salinity Gradients (40 CFR 230.25)

Salinity gradients form where salt water from the ocean meets and mixes with freshwater from land. Sections 3.5, Physical Oceanography and Coastal Processes; 3.6, Hydrology; and 3.7, Water Quality of the Draft EIS describe salinity gradients in aquatic environments in the project area.

The salinity of nearshore waters along the Beaufort Sea coast is strongly influenced by seasonal sea ice and meteorological conditions. Sea ice begins to form in Beaufort coastal lagoons between mid-September and mid-October. Under the ice, the water column is well mixed, with temperature fluctuating around 29°F (-1.5°C) and high salinity (32.4 ppt). During spring breakup in early June, freshwater overflows the sea ice at the river mouths, causing some melting of the sea ice surface and resulting in a freshwater layer in the water column which can extend as deep at 13 feet over a marine water layer (URS 1999). As the open-water season progresses, coastal waters become colder and more saline due to vertical mixing, and as solar strength and freshwater input diminish (Colonell and Niedoroda 1990).

The location of offshore barrier islands and major rivers also play a role in influencing fresh, brackish, and marine waters mixing in the Lion Bay area. The Canning/Staines River is the major freshwater input into the bay. The barrier islands act as a natural barrier for brackish water entering the greater Lion Bay

marine environment (URS 2000). When the wind currents originate from the west, fresh water from the Sagavanirktok and Shaviovik Rivers, located approximately 40 miles west of Lion Bay, moves eastward along the surface and shoreline. This freshwater thoroughly mixes with marine water at lower depths to become brackish water by the time it reaches Lion Bay (URS 1999).

In the freshwater environment, the salinity and water quality of streams in the project area are influenced by spring breakup, precipitation events, surface runoff, and by saltwater intrusions from the Beaufort Sea. Several thaw lakes and ponds along the coastal area and near the pad locations are influenced by saline water from storm surges, ocean spray, and inundated troughs (microlows) connecting the Beaufort Sea estuaries to coastal lakes. Concentrations of total dissolved solids (TDS) in both lakes and streams in the project area increase the closer they are to the Beaufort Sea. Near the mouth where streams empty into the bay, conductivity values indicates mixing of freshwater with marine waters. Closer to the coast, water bodies tend to be dominated by sodium chloride (ocean-derived salt). Farther from the coast, water bodies are dominated by calcium bicarbonates, indicative of freshwater.

1.6.1. Potential Impacts

The analysis of impacts related to the salinity gradients will include consideration of changes in existing salinity gradients resulting from obstructions which divert or restrict flow of either fresh or salt water. For example, changes in the movement of the salt water into and out of that area can effectively lower the volume of salt water available for mixing within that estuary. The downstream migration of the salinity gradient can occur, displacing the maximum sedimentation zone and requiring salinity-dependent aquatic biota to adjust to the new conditions, move to new locations if possible, or perish. In the freshwater zone, discharge operations in the upstream regions can have equally adverse impacts. A significant reduction in the volume of fresh water moving into an estuary can affect the location and type of mixing thereby changing the characteristic salinity patterns. The resulting changed circulation pattern can cause the upstream migration of the salinity gradient displacing the maximum sedimentation zone. This migration may affect those organisms that are adapted to freshwater environments.

Information regarding the impacts of the proposed project activities on salinity gradients in the project area may be found in Sections 5.6, Hydrology; and 5.7, Water Quality of the Draft EIS. The Draft EIS impact analysis of the proposed discharge on salinity gradients will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

2. Subpart D: Potential Impacts on the Biological Characteristics of the Aquatic Ecosystem

2.1. Threatened and Endangered Species (40 CFR 230.30)

An endangered species is a plant or animal in danger of extinction throughout all or a significant portion of its range. A threatened species is one in danger of becoming an endangered species in the foreseeable future throughout all or a significant portion of its range. Threatened and endangered species that may be affected by the proposed project are described in Sections 3.9, Birds and 3.11, Marine Mammals of the Draft EIS. Furthermore, the Applicant requested designation as the "non-federal representative" to prepare Biological Assessments (BA) for threatened and endangered species as part of Section 7 of the ESA; the Corps approved the request and the BAs for all threatened and endangered species in the project area are included as Appendix M of the Draft EIS.

2.1.1. Birds

The project area provides habitat for two species of birds, the Steller's eider and spectacled eider, which have been federally listed as threatened under the ESA, and one species of bird, the yellow-billed loon, which is under consideration for listing as threatened.

Both the Steller's eider and spectacled eider have had critical habitat designated in western Alaska, but no critical habitat for either bird has been designated on the ACP or within the project area. Currently, the Barrow area appears to be the center of abundance and primary nesting area for the low densities of Steller's eiders that do occur on the ACP. Steller's eiders have been observed since the 1970s in the Kadleroshilik, Shaviovik, and Canning River deltas and at Bullen Point during May to September (Quakenbush, et al. 2002). However, neither nesting or post-nesting Steller's eiders have been recorded in the Point Thomson study area in recent years and the study area appears to be east of the Steller's eiders' recently document breeding range and post-breeding and molting area (Fischer et al. 2002, Fischer and Larned 2004)

On the ACP, nearly all spectacled eiders breed north of 70° latitude between Icy Cape and the Shaviovik River, within about 50 miles of the coast (65 FR 6114). Within this region, most spectacled eiders occur between Cape Simpson and the Sagavanirktok River. During four years of surveys conducted between 1998 and 2001, 100 percent coverage surveys for eiders in a portion of the Point Thomson study area documented seven pairs of spectacled eiders (TERA 2000, 2002). Zero to three pairs of spectacled eiders occurred within the Point Thomson Unit survey area, resulting in an average annual nesting density of less than 1 pair/mi^2 within the 76.7 mi^2 survey area (TERA 2002). A 2010 aerial nesting survey of the study area did not document any spectacled eiders (Johnson et al. 2011).

Yellow-billed loon density in the study area is also very low (Larned et al. 2009). No yellow-billed loon nests have been found in the Point Thomson study area, although the breeding pair survey data and density contours indicate there may be nest habitat about 14 miles southwest of the project area. A study area-specific aerial survey for nesting yellow-billed loons was conducted in 2010 and no nesting birds were observed (Johnson et al. 2011). However, yellow-billed loons have been observed using coastal areas in the study area for summer foraging (Fischer et al. 2002, Rodrigues 2002a, 2002b, Noel et al. 2003, Fischer and Larned 2004) and for fall staging and migration (WCC and ABR 1983). An average of two yellow-billed loons were observed during late-June or early July coastal surveys during between 1999 and 2009, while an estimated six yellow-billed loons use the nearshore and lagoon habitats in the study area.

2.1.2. Marine Mammals

The project area provides habitat for one species of marine mammal, the bowhead whale which has been federally listed as endangered under the ESA, one species of marine mammal, the polar bear which has been federally listed as threatened, and two species of marine mammal, the bearded seal and ringed seal, which are under consideration for listing as threatened.

The bowhead whale, which was listed as endangered by the National Marine Fisheries Service (NMFS) in 1970, prefers shallow, continental shelf waters and is associated with relatively heavy ice cover for much of the year. The extent, nature, and location of ice cover in the Beaufort Sea appear to influence the timing, duration, and location of the bowhead whale migration. In May and June, most bowhead whales from the Western Stock migrate eastward along the Beaufort Sea coast, seaward of the barrier islands, though some remain to feed off Barrow. The spring migration tends to occur far offshore, outside of the

Point Thomson study area. The return westward migration, starting in August and lasting through October, also occurs primarily seaward of the barrier islands, but closer to shore than the spring migration. A large proportion of the population transits through the Point Thomson study area at this time, but few whales pass landward of the barrier islands.

In May 2008, the USFWS listed the polar bear as a threatened species due to concerns over the threat to polar bear habitat posed by the trend of rapidly diminishing sea ice cover and thickness in the Arctic Ocean. Designated critical habitat includes (1) sea ice habitat over the continental shelf; (2) terrestrial denning habitat; and (3) barrier island habitat. All three types of critical habitat can be found in the Point Thomson study area. The Southern Beaufort Sea (SBS) stock of polar bears is the only stock that occurs in the project area. Although polar bears may be encountered year-round in nearshore and coastal areas of the Beaufort Sea (Schliebe, et al. 2006), individuals are usually absent from the study area during early summer (June-July). Numbers begin to increase in the project area in August and peak in September; these bears are believed to be moving through the area to reach newly-forming pack ice to forage. The barrier islands in the study area, especially Flaxman Island, are consistently used by denning females from fall through winter (Durner, et al. 2006, Smith, et al. 2007), although the number of denning bears is relatively small compared to other known denning areas.

On December 10, 2010, NMFS proposed listing five subspecies of ringed seals and one subspecies of bearded seal as threatened due to the threat posed by a decline in sea ice with which they are closely associated (Cameron, et al. 2010, Kelly, et al. 2010). The ringed seal is the most abundant marine mammal in the Beaufort sea while the bearded seal is the second most common seal species in the Beaufort Sea (Frost, et al. 1988, Funk, et al. 2010, Kelly, et al. 2010, Laidre, et al. 2008). The density and distribution of both species varies between nearshore and offshore waters by season and ice cover (Moulton and Lawson 2002, Kelly, et al. 2010, Kovacs 2008, Cameron, et al. 2010). Ringed seals are expected to occur commonly in and near the study area in coastal waters during the summer/fall open-water season. During winter and spring, the proportion of ringed seals in the study area is anticipated to be small relative to the estimated size of the Beaufort Sea population, given existing records and the limited availability of ice habitat with suitable water depths. Bearded seals, which are normally found in broken ice that is unstable, typically only inhabit the Beaufort Sea during the summer. This species is also unlikely to occur in the study area in winter or early spring.

2.1.3. Potential Impacts

The analysis of impacts on threatened or endangered species will include consideration of direct impacts such as the killing of a species individual; the facilitation of incompatible activities; or the impairment or destruction of habitat to which a species is limited. The characteristics of aquatic habitats that are particularly crucial to the continued survival of threatened or endangered species will be evaluated, including consideration of water quality; spawning and maturation areas; nesting areas; protective cover; adequate and reliable food supply; and resting areas for migratory species. Potential impacts to crucial aquatic habitats may include changes in normal water conditions for clarity, chemical content, nutrient balance, DO, pH, temperature, salinity, current patterns, circulation, and fluctuations.

Sections 5.9, Birds and 5.11, Marine Mammals of the Draft EIS discuss potential impacts to threatened and endangered species in the project area. The Draft EIS impact analysis of the proposed discharge on these species will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

2.2. Aquatic Food Web (40 CFR 230.31)

Aquatic organisms in the food web include fish, invertebrates, and the plants and animals on which they feed and depend upon for their needs. Section 3.12, Fish, Essential Fish Habitat, and Invertebrates of the Draft EIS describes organisms in the aquatic food web.

Fifty-eight species of fish have been found in the nearshore marine environment near the project area. Thirteen species of fish have been documented in the freshwater habitats of the study area. Eight fish species were identified as species of importance or concern for the Point Thomson Project. These include arctic cisco, least cisco, Dolly Varden, arctic grayling, broad whitefish, humpback whitefish, arctic cod, and pacific salmon.

Marine habitat for fish in the study area includes coastal waters between the Canning/Staines and Sagavanirktok Rivers; Lion Bay, Mikkelsen Bay, Foggy Island Bay, and portions of the Canning/Staines and Sagavanirktok River deltas. The marine study area, particularly the nearshore environment, is used by fish species for migration (e.g., adult Pacific salmon, adult and immature arctic cisco and Dolly Varden), foraging (e.g., adult arctic cisco, least cisco, Dolly Varden, broad whitefish, and humpback whitefish), and spawning (e.g., arctic cod).

Freshwater habitat of the study area includes shallow, seasonally flooded ponds and wetlands, small tundra streams, and larger, braided rivers and streams. Most freshwater habitat in the study area is available only during the open water season because most of these habitats freeze to the bottom during winter. Overwintering habitat in the study area is rare due to the shallow depth of most lakes, ponds, and streams. Some aquatic invertebrates overwinter in frozen sediments. Freshwater habitat is reduced by 95 percent by late winter (Craig 1989). Overwintering sites for Dolly Varden include portions of the Canning/Staines, Sagavanirktok, Kavik, and Shaviovik Rivers.

In addition to fish species, invertebrates, algae, and phytoplankton are also critical components of marine and freshwater habitats in the study area. Invertebrates include a diverse array of organisms such as polychaete and oligochaete worms, clams, crustaceans (which include a diversity of species from microscopic sized copepods and amphipods to large crabs), and insects (particularly larval forms). Aquatic invertebrates are the primary food for many fish and marine mammal species. Primary productivity in the marine environment is primarily driven by epontic (ice) algae and phytoplankton in the spring and early summer and phytoplankton in the mid to late summer.

2.2.1. Potential Impacts

The analysis of impacts related to the aquatic ecosystem and food web will include consideration of the debilitation or death of organisms by smothering, exposure to chemical contaminants in dissolved or suspended form, exposure to high levels of suspended particulates, reduction in food supply, or alteration of the substrate upon which aquatic organisms are dependent. Sedentary organisms are particularly sensitive to the discharge of material during periods of reproduction, growth, and development due to their limited mobility. An increase in suspended particulates can also result in the smothering of attached or buried eggs of many organisms by limiting or sealing off their exposure to oxygenated water.

Impacts on populations of fish and invertebrates may also occur through the release of contaminants which can adversely affect adults, juveniles, larvae, or eggs. Increased contaminants also may result in the establishment or proliferation of an undesirable competitive species of plant or animal at the expense of the desired resident species. The discharge of dredged or fill material can redirect, delay, or stop the

reproductive and feeding movements of some species of fish and invertebrates, thus preventing their aggregation in accustomed places such as spawning or nursery grounds and potentially leading to reduced populations. Reduction of detrital feeding species or other representatives of lower trophic levels can impair the flow of energy from primary consumers to higher trophic levels. The reduction or potential elimination of food chain organism populations may decrease the overall productivity and nutrient export capability of the ecosystem.

For the proposed Point Thomson Project, key considerations in the evaluation of impacts on aquatic ecosystems include the maintenance of adequate winter habitat, suitable feeding and spawning habitats, and passage to and from these areas for fish and invertebrates. Section 5.12, Fish, Essential Fish Habitat, and Invertebrates of the Draft EIS discuss potential impacts to aquatic ecosystems and organisms in the project area. The Draft EIS impact analysis of the proposed discharge on these species will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

2.3. Other Wildlife (40 CFR 230.32)

Wildlife associated with aquatic ecosystems includes resident and transient mammals and birds. Sections 3.9, Birds; 3.10, Terrestrial Mammals; and 3.11, Marine Mammals of the Draft EIS describe other wildlife present in the Point Thomson Project area.

2.3.1. Birds

More than 70 bird species have been documented in the study area. Of these, 29 are listed as species of concern by the USFWS, Audubon, and/or Alaska Shorebird Group because of small population sizes, population declines, sensitivity to disturbance, or other reasons. Two of these 29 species, the spectacled eider and Steller’s eider, are also listed as threatened under the ESA and one of them, the yellow-billed loon, is a candidate species for listing; however, these three species are considered uncommon in the study area.

Bird groups that occur in the project area include waterbirds such as waterfowl, loons, cranes, seabirds, and shorebirds, and landbirds such as raptors, owls, ptarmigan, and songbirds. Waterbirds dominate the study area because of the abundance of surface water caused by the underlying permafrost. All waterbirds in the study area are migratory as aquatic habitats are frozen during the winter. Most waterfowl, ducks, geese, and swans use aquatic habitats in the study area between May and September for spring and fall migration (resting and foraging), nesting, molting, and escape cover. Bird use of tundra habitats in the study area is low relative to habitats to the east and west. However, the Sagavanirktok River delta provides high quality habitat for numerous species. The shoreline and coastal lagoons in the study area provide important post-nesting and molting habitat for birds, and these habitats are included in the Eastern Beaufort Sea Lagoons and Barrier Islands Important Bird Area.

2.3.2. Terrestrial Mammals

Terrestrial mammal groups represented in the study area include rodents (ground squirrels, lemmings, and voles), carnivores (shrews, foxes, bears, and weasels), and ungulates (caribou and muskoxen). Terrestrial mammals of concern for the Point Thomson project are caribou, muskoxen, brown bears, foxes, and small mammals.

Caribou use the study area for calving, summer foraging, and parasitic insect relief. During this time, caribou, potentially from several herds, are constantly on the move within, into, and out of the Point

Thomson area as they forage and seek relief from insects. The Central Arctic Herd is the predominant herd in the study area. Caribou calving ranges and post-calving movements vary from year to year depending on a variety of factors (e.g., weather, forage condition, insect abundance and activity, predators, disturbance). Caribou are an important subsistence resource and also are hunted recreationally.

The muskoxen population in the study area descends from a herd of muskoxen that was reintroduced to the North Slope between 1969 and 1970. Following reintroduction, the North Slope population declined from over 500 animals to about 200 animals between the late 1990s and the mid-2000s; in recent years the population appears to have stabilized at around 200. Muskoxen use the study area year-round, using riverine and riparian habitats in the summer and windswept hilltops, slopes, and plateaus in winter.

Brown bears occur at a low to moderate density on the North Slope. Bears spend between 5 and 8 months in dens, which are commonly located in streambanks, hillsides, and terraces where snow accumulates. Within the study area, brown bear dens have been documented between the Sagavanirktok and Shaviovik Rivers. During their active period, brown bears range widely for food. Within the study area they have been observed foraging and moving through riparian habitats.

Arctic foxes spend summers on land and winters primarily along the coast and on sea ice. Red foxes tend to be most abundant in the foothills and riparian areas on the North Slope. Arctic foxes are attracted to human development and their numbers on the North Slope have been stable in recent years. Red and arctic foxes compete for resources. Where they occur together, the larger red fox often displaces the smaller arctic fox.

Small mammals, such as arctic ground squirrels, collared and brown lemmings, root voles, and barren ground shrews occur in the study area. Small mammals are an integral part of the arctic ecosystem as they form the prey base for many mammals and birds.

2.3.3. Marine Mammals

There is documented occurrence of 16 marine mammal species within or adjacent to the study area: five baleen whale species, four toothed whale species, six pinniped species, and the polar bear. However, nine of these species do not regularly occur in the Beaufort Sea and are not likely to occur in the Point Thomson area. Species of concern for the proposed Point Thomson project include: the bearded seal, beluga whale, bowhead whale, polar bear, and ringed seal. Of these, the bowhead whale and polar bear are listed as threatened or endangered under the ESA while the bearded seal and ringed seal have been proposed for listing as threatened. Of the three non-threatened/non-endangered marine mammal species with occurrence in the study area, only the beluga whale is anticipated to occur regularly, and only in relatively low numbers. The two other species (gray whale and spotted seal) have a rare occurrence (i.e., sporadically occurring in the study area).

The general distribution pattern for beluga whales in the Beaufort Sea shows major seasonal changes (Allen and Angliss 2010). During the winter, they occur in offshore waters associated with pack ice. In the spring, beluga whales migrate to warmer coastal estuaries, bays, and rivers where they may molt, give birth, and care for their calves. Small numbers of beluga whales of the Beaufort Sea stock may occur in the study area seaward of the barrier islands, most likely during the fall westward migration from late August through mid-September. It is possible, though highly unlikely, that a few belugas from the Eastern Chukchi Sea stock could occur in the study area, also during the fall westward migration from late August to mid-September. No belugas are expected in the region during the winter and spring seasons.

2.3.4. Potential Impacts

The analysis of impacts related to other wildlife will include consideration of the loss or change of breeding and nesting areas, escape cover, travel corridors, and preferred food sources for resident and transient wildlife species associated with the aquatic ecosystem. Adverse impacts upon wildlife habitat may result from changes in water levels, water flow and circulation, salinity, chemical content, substrate characteristics, and elevation. Increased water turbidity can adversely affect wildlife species which rely upon sight to feed, and disrupt the respiration and feeding of certain aquatic wildlife and food chain organisms. An increase in the availability of contaminants from the discharge of dredged or fill material may lead to the bioaccumulation of such contaminants in wildlife. Changes in physical and chemical factors of the environment may favor the introduction of undesirable plant and animal species at the expense of resident species and communities. In some aquatic environments lowering plant and animal species diversity may disrupt the normal functions of the ecosystem and lead to reductions in overall biological productivity.

Impacts to other wildlife are discussed in Section 5.9, Birds; 5.10 Terrestrial Mammals; and 5.11 Marine Mammals of the Draft EIS. Additional impacts are detailed in Appendix L, Bird Nesting and Breeding Tables of the Draft EIS. The Draft EIS impact analysis of the proposed discharge on these species will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

3. Subpart E: Potential Impacts on Special Aquatic Sites

Special aquatic sites are geographic areas, large or small, possessing special ecological characteristics of productivity, habitat, wildlife protection, or other important and easily disrupted ecological values. These areas are generally recognized as significantly influencing or positively contributing to the general overall environmental health or vitality of the entire ecosystem of a region (See 40 CFR 230.10(a)(3)).

3.1. Sanctuaries and Refuges (40 CFR 230.40)

Sanctuaries and refuges consist of areas designated under State or Federal laws or local ordinances to be managed principally for the preservation and use of fish and wildlife resources. Section 3.14, Arctic National Wildlife Refuge of the Draft EIS, discusses the only sanctuary in proximity to the project area.

The Arctic Refuge is part of the National Wildlife Refuge system. The western edge of the Canning/Staines River delta forms the western refuge boundary, which lies approximately 5.5 miles from the current Point Thomson development area and about 2 miles from the proposed East Pad location in Alternative B. The Arctic Refuge includes 19 million acres, 8 million acres of which are designated as Molly Beattie Wilderness. The Point Thomson project site is located 30 miles northwest of the Molly Beattie Wilderness area.

The Arctic Refuge as a whole contains the greatest diversity of wildlife species of any protected area in the circumpolar north, including nearly 45 mammal, 180 bird, and 36 fish species (USFWS 2008). Many fish and wildlife resources are shared by the Arctic Refuge and the proposed project area, creating the potential for impacts on resources within the Arctic Refuge from the Point Thomson Project. In addition, impacts to wetlands, vegetation, recreation, visual aesthetics, and noise in the project area may also extend in the Arctic Refuge. These impacts are discussed by resources, elsewhere in this evaluation (see Sections 3.2, Wetlands, 4.3, Water-Related Recreation, and 4.4, Aesthetics); resource impacts specific to the Arctic Refuge are discussed below.

3.1.1. Potential Impacts

The analysis of impacts related to sanctuaries and refuges in the project area will include consideration of the disruption of the breeding, spawning, migratory movements, or other critical life requirements of resident or transient fish and wildlife; the creation of easy and incompatible human access to remote aquatic areas; the creation of the need for frequent maintenance activity; the establishment of undesirable competitive species of plants and animals; changes in the balance of water and land areas needed to provide cover, food, and other fish and wildlife habitat requirements in a way that modifies sanctuary or refuge management practices; and any other adverse impacts discussed in Subparts C, D, or F (Sections 1, 2, and 4) as they relate to a particular sanctuary or refuge.

Section 5.14, Arctic National Wildlife Refuge of the Draft EIS, discusses the potential for impacts to the Arctic Refuge that may occur as the result of the proposed Point Thomson Project. . The Draft EIS impact analysis of the proposed discharge on these species will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

3.2. Wetlands (40 CFR 230.41)

Wetlands consist of areas that are inundated or saturated by surface or ground water at a frequency or duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Section 3.8, Vegetation and Wetlands of the Draft EIS and Appendices J, Mapped Land Cover and Wetlands, and K, Wetland Functional Assessment of the Draft EIS, discuss the prevalence and location of wetlands in the project area.

Vegetation on the ACP is dominated by cold and high-moisture tolerant species. Small topographic differences affect soil moisture which, in turn, strongly affects the vegetation of any site. Margins of thaw lakes, drained thaw lake basins, ice-wedge polygon troughs, and low-centered polygons, all features common to the study area, tend to be saturated throughout the growing season and have high-moisture tolerant species, including sedges or grasses occupying lower wetter areas, and dwarf scrub communities occupying areas with better drainage (Gallant, et al. 1995).

The aquatic ecosystems of the project area are characterized by extensive wetland and water body habitats. Mapped areas include terrestrial and marine areas in and near where infrastructure is proposed for all alternatives. Seventy-one percent (45,796 acres) of the mapped study area is covered by wetlands, notably wet tundra (28 percent), moist tundra (22 percent), and moist/wet tundra complexes (17 percent). Table 6.1 describes the cover classes common in Point Thomson study area wetlands.

Table 6.1: Wetland Cover Classes found in the Point Thomson Study Area

Class	Description
Wet tundra	Occupies wetter environments such as drained lake basins and poorly drained river terraces. Typically characterized as saturated or inundated emergent and scrub-shrub wetland. Ranges from saturated to permanently flooded.
Moist tundra	Covers broad expanses of open tundra above shallow water tables. Moist tundra is characterized as saturated wetland, dominated by scrub-shrub and emergent vegetation.
Wet/moist complex	Includes areas of tundra with a mosaic of wet and moist tundra, generally with moist ridges dominated by dwarf shrubs and wetter basins dominated sedges. Common in drier portions of drained lake basins and on poorly drained river terraces. Wet/moist tundra complexes are generally characterized as saturated or inundated emergent and scrub-shrub wetland, ranging from seasonally saturated to permanently flooded.

Wetlands serve important biological and ecological functions and support key bird, terrestrial mammal, and fish habitat within the study area. Some of the most prevalent functions served by wetlands in the study area include:

- Maintenance of soil thermal regime (62 percent of study area)
- Waterbird support (56 percent of study area)
- Resident and diadromous fish support (38 percent of study area)
- Production and export of organic matter (29 percent of study area)
- Flood flow moderation and conveyance (28 percent of study area)

Water bodies include unvegetated intertidal and subtidal bays and inlets, rivers, streams, lakes, ponds, and their associated barren mud flats, gravel bars, and drained lake basins. Water bodies and their associated barrens occupy approximately 29 percent (18,354 acres) of the study area and comprise areas of open water (26 percent), river gravels/beaches (2 percent), wet mud (1 percent) and bare peat (less than 0.1 percent) associated with lakes, ponds, and coastal areas.

Areas not classified as water bodies or wetlands are considered uplands. Uplands occupy less than one percent (205 acres) of the study area. Areas mapped uplands include existing, man-made gravel pads. Vegetation types that may be a mosaic of upland and wetland, however, are considered wetland for this analysis. Upland areas serve as well-drained components in mosaics of wetland habitat and consist of a typically higher diversity of plant species than in the surrounding wetlands.

3.2.1. Potential Impacts

The analysis of impacts related to wetlands will include consideration of potential for the damage or destruction of wetland habitat resulting from adverse impacts to the biological productivity of wetlands ecosystems by smothering, dewatering, permanently flooding, altering substrate elevation, or altering periodicity of water movement. The addition of dredged or fill material may destroy wetland vegetation or result in advancement of succession to dry land species. Other impacts may include the reduction or elimination of nutrient exchange by a reduction of the system's productivity, or by altering current patterns and velocities. Disruption or elimination of the wetland system can degrade water quality by obstructing circulation patterns that flush large expanses of wetland systems, by interfering with the filtration function of wetlands, or by changing the aquifer recharge capability of a wetland.

The discharge of fill material can also change the wetland habitat value for fish and wildlife as discussed in Subpart D (Section 2). When disruptions in flow and circulation patterns occur, apparently minor loss of wetland acreage may result in major losses through secondary impacts. Discharging fill material in wetlands may modify the capacity of wetlands to retain and store floodwaters and to serve as a buffer zone shielding upland areas from wave actions, storm damage and erosion.

Section 5.8, Vegetation and Wetlands of the Draft EIS, discusses the potential impacts to wetlands under all Draft EIS alternatives. The Draft EIS impact analysis of the proposed discharge on wetland ecosystems will be incorporated into this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

3.3. Mudflats (40 CFR 230.42)

Mudflats are broad flat areas along the sea coast and in coastal rivers to the head of tidal influence and in inland lakes, ponds, and riverine systems. The substrate of mudflats contains organic material and particles smaller in size than sand. They are either un-vegetated or vegetated only by algal mats. The prevalence and location of mudflats in the project area is also discussed in Section 3.8, Vegetation and Wetlands and Appendix J, Mapped Land Cover and Wetlands of the Draft EIS.

Mudflats are not common in the project area and are primarily found near the mouths of the Sagavanirktok and Shaviovik Rivers. Mudflats were captured in vegetation mapping of the project area in the Wet Barren/Wet Graminoid Tundra Complex (barren/saline tundra complex/saltmarsh; vegetation class IXh) and River Gravels and Beaches (vegetation class Xa). Wet Barren/Wet Graminoid Tundra Complexes include Estuarine Intertidal, Regularly Flooded Mud Flats (NWI classes E2USN and E2USP) as the dominant cover present as large patches of wet mud interspersed among Emergent Intertidal (E2EM1P) saline tolerant plants. River Gravels and Beaches include Riverine, Seasonally Flooded Areas (NWI classes R2USC and R3USC) and Estuarine, Intertidal, Irregularly Flooded Areas (NWI class E2US1P). Mudflats captured by vegetation class Xa were identified by hand based on aerial interpretation and proximity to the coast and were distinguished from river gravels and beaches within this class.

3.3.1. Potential Impacts

The analysis of impacts related to mudflats will include consideration of the potential for changes in water circulation patterns, which may permanently flood or dewater the mud flat or disrupt periodic inundation, resulting in an increase in the rate of erosion or accretion. Such changes can deplete or eliminate mud flat biota, foraging areas, and nursery areas. Changes in inundation patterns can affect the chemical and biological exchange and decomposition process occurring on the mud flat and change the deposition of suspended material affecting the productivity of the area. Changes may reduce the mudflat's capacity to dissipate storm surge runoff.

Appendix J, Mapped Land Cover and Wetlands of the Draft EIS discusses the location and prevalence of mudflats in the project area and provides the basis for analysis of impacts to mudflats by Draft EIS alternative. Impact analysis of the proposed discharge on wetland ecosystems will be included in this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

3.4. Vegetated Shallows (40 CFR 230.43)

Vegetated shallows are permanently inundated areas that under normal circumstances support communities of rooted aquatic vegetation, such as turtle grass and eelgrass in estuarine or marine systems

as well as a number of freshwater species in rivers and lakes. The location of vegetated shallows in the project area is presented in Section 3.8, Vegetation and Wetlands and Appendix J, Mapped Land Cover and Wetlands of the Draft EIS.

Freshwater vegetated shallows in the project area were captured in the vegetation mapping in the Aquatic Graminoid Tundra (emergent vegetation; vegetation class IIb) and Water/Tundra Complex (interconnected ponds with emergent vegetation; vegetation class IId) classes. Aquatic Graminoid Tundra includes Lacustrine and Palustrine permanently flooded emergent marshes (NWI classes L2EM2H and PEM1H) which primarily include communities dominated by *Arctophila fulva* and *Carex aquatilis* associated with the shallow waters of ponds, lakes, and slow moving streams. Water/Tundra Complex vegetation includes Lacustrine and Palustrine complexes of open water and emergent vegetation (NWI classes L2UB/EM2H and PUB/EM2H) which primarily include complexes of water and intervening tundra. Water is the dominant land cover with large areas of emergent vegetation in the water bodies.

In addition to these two primary vegetated shallows classes, some vegetated shallows may also be captured under the Wet Sedge Tundra/Water Complex class (vegetation class IIIc), which includes Lacustrine and Palustrine complexes of emergent vegetation and open water (NWI classes L2EM2/UBH and PEM1/UBH). Only those areas of this class that are associated with permanent water bodies were included as vegetated shallows.

In the marine ecosystem, vegetated shallows in the project area are captured in the vegetation mapping in the Wet Graminoid Tundra (wet saline tundra/salt marsh; vegetation class IIIb). This class includes Estuarine Emergent Intertidal vegetation (NWI classes E2EM1N AND E2EM1P), which primarily includes communities dominated by saline tolerant graminoid species present at the mouths of rivers and streams.

3.4.1. Potential Impacts

The analysis of impacts related to vegetated shallows will include consideration of the potential for the smothering or creation of unsuitable conditions for vegetation or benthic organisms as a result of:

1) changing water circulation patterns;

2) releasing nutrients that increase undesirable algal populations;

3) releasing chemicals that adversely affect plants and animals;

4) increasing turbidity levels, thereby reducing light penetration and hence photosynthesis; and

5) changing the capacity of a vegetated shallow to stabilize bottom materials and decrease channel shoaling.

The discharge of dredged or fill material may reduce the value of vegetated shallows as nesting, spawning, nursery, cover, and forage areas, as well as their value in protecting shorelines from erosion and wave actions. It may also encourage the growth of nuisance vegetation.

All vegetated shallows in the project area fall under the definition of wetlands as they are “areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.” Vegetated shallows that do not fall under the wetlands definition (such as eelgrass beds) do not exist in the project area. Thus, all impacts to vegetated shallows will be considered

under the discussion of wetland impacts in Section 3.2, Wetlands. No additional impacts to vegetated shallows, beyond those already discussed for wetlands, are expected to occur.

3.5. Coral Reefs (40 CFR 230.44)

Coral reefs consist of the skeletal deposit of anthozoan polyps or other invertebrate organisms present in growing portions of a reef. Corals are rare in the Alaskan Beaufort Sea due to the lack of hard rock substrates needed for attachment. The Alaskan Beaufort Sea shelf is blanketed predominantly by silty sands and muds (Dunton, et al. 1982).

A small population of corals does exist, however, in the Boulder Patch, an unusual Beaufort Sea ecosystem offshore of the Endicott causeway in Stefansson Sound. The Boulder Patch is characterized by abundant kelp and diverse invertebrate fauna attached to cobbles and boulders in an area where the benthic environment is protected from ice movement by offshore islands and shoals (Dunton, et al. 1982). One species of soft coral, *Gersemia rubiformis*, has been identified living on the rock substrates. The Boulder Patch is not within the immediate vicinity of Point Thomson, but is considered within the project area as it may be traversed by coastal barges transporting goods and materials from Deadhorse to Point Thomson (ExxonMobil 2011b).

The Boulder Patch has been extensively studied for potential impacts related to the oil and gas development at Endicott. No adverse effects have been detected on the community health or diversity (Martin and Gallaway 1994).

3.5.1. Potential Impacts

The analysis of impacts related to coral reefs will include consideration of the potential for changes related to sedimentation, degradation of water quality, and the reduction of the penetration of light through the water column.

3.6. Riffle and Pool Complexes (40 CFR 230.45)

Riffle and pool complexes sometimes characterize steep gradient sections of streams where the rapid movement of water over a course substrate in riffles results in rough flow, a turbulent surface, and high DO levels. Riffles are intermixed with pools, which are characterized by slower stream velocity, a steaming flow, smooth surface, and a finer substrate. Riffle and pool complexes are particularly valuable habitat for fish and wildlife. There are no riffle and pool complexes identified in the project area.

4. Subpart F: Potential Effects on Human Use Characteristics

4.1. Municipal and Private Water Supplies (40 CFR 230.50)

Municipal and private water supplies consist of surface or ground water which is directed to the intake of a municipal or private water supply system. There are no municipal or private water supplies in the project area at this time. However, under the development of any of the action alternatives, the C-1 reservoir would be used as a potable water source during the construction of the Point Thomson development. Under Alternatives B, C, and E, the C-1 reservoir would continue to be the primary water source for the life of the project, with the rehabilitated gravel mine, which will be developed during construction, serving as a secondary water source. Under Alternative D, the rehabilitated gravel mine would be the primary water source during drilling and for the life of the project operations.

Impacts related to water supplies may include, but are not limited to, changes in the color, taste, odor, chemical content, and suspended particulate concentration, in such a way as to reduce the fitness of the

water for consumption. Water can be rendered unpalatable or unhealthy by the addition of suspended particulates, viruses and pathogenic organisms, and dissolved materials. The expense of removing such substances before the water is delivered for consumption can be high. Discharges may also affect the quantity of water available for municipal and private water supplies. In addition, certain commonly used water treatment chemicals have the potential for combining with some suspended or dissolved substances from dredged or fill material to form other products that can have a toxic effect on consumers.

The use of the C-1 reservoir as a water source, existing water quality in the project area, and potential impacts to water quality from the Point Thomson project are discussed in Sections 2.4, Alternative Descriptions; 3.7, Water Quality; and 5.7 Water Quality of the Draft EIS. Water quality is further discussed in Section 1.3, Water Quality and Chemistry, above.

4.2. Recreational and Commercial Fishing (40 CFR 230.51)

Recreational and commercial fisheries consist of harvestable fish, crustaceans, shellfish, and other aquatic organisms used by humans. In the context of this Guidelines evaluation, it also includes subsistence fishing by local residents. The aquatic ecosystem in the project area supports human use through commercial and recreational fishing. Recreational fishing includes recreational fishing by non-local residents and subsistence fishing by local residents. Of these uses, subsistence fishing by local residents is the most common consumptive use of the aquatic resources. Sections 3.11, Marine Mammals; 3.12, Fish, Essential Fish Habitat, and Invertebrates; 3.18, Recreation; and 3.22 Subsistence and Traditional Land Use of the Draft EIS discuss the availability and harvest of marine mammals and fish in the project area.

Commercial fishing in the NSB is limited. In 2010, just five NSB residents held commercial fishing permits for arctic cisco in the Colville River, located west of the project area (ADCCED 2011). While no commercial fishing occurs in the vicinity of the project area, arctic cisco harvested in the Colville River use the project area as feeding, rearing, and migration habitat. Arctic cisco of younger age classes also overwinter in the Sagavanirktok River, on the western edge of the project area.

Recreational fishing by non-local residents occurs in the Point Thomson Project area; however, fishing is rarely the primary reason for recreational visits to the area. Most recreational use of the project area by non-local residents occurs along the Canning River, which forms the boundary between state land and the Arctic Refuge. Non-local residents occasionally kayak along the coastal corridor as well. All recreational use of the project area occurs at low levels; there may be no more than about 100 non-local recreationists on the ground in the area in a given year. Most non-local recreational visitors to the Arctic Refuge state indicate that solitude and experience of the “wilderness values” are primary motivators for their visit while hunting, river rafting, and hiking/backpacking are primary recreational activities (Christensen and Christensen 2009). However, a large proportion of non-local recreational visitors are believed to fish during their visits to the Arctic Refuge, even though fishing usually is not a primary reason for visiting. Non-local recreational fishing in the project area most likely to targets freshwater and diadromous species of fish.

The primary human use of fish, invertebrates, and other aquatic organisms, including marine mammals, in the project area is subsistence harvest by residents of local communities. The communities of Kaktovik and Nuiqsut are the two closest communities to the Point Thomson Project area and both communities use areas in or adjacent to the Point Thomson project area for subsistence purposes. In addition, residents from these communities also harvest subsistence resources which may migrate through the project area.

For the community of Kaktovik, the subsistence harvest of marine mammals provides a large portion (between 17 to 79 percent in the five years studied) of the total subsistence harvest by weight; fish harvests varied between 4 and 18 percent of the total annual subsistence harvests in those same years (Fuller and George 1999, Bacon, et al. 2009, ADF&G 2011). The yearly contribution of all species fluctuates depending on resource availability and harvest success. Kaktovik residents use the project area primarily for the harvest of caribou, however, residents report fishing along the coast in the project vicinity. Subsistence harvest of other aquatic resources, such as seals and waterfowl, also occurs at a minimal level in the project area, primarily in conjunction with the summer caribou hunt. Bowhead whale hunting for the community of Kaktovik does not occur in the project area, but residents expressed concern that bowhead whale harvests could be impacted if contamination of marine resources occurs.

For the community of Nuiqsut, the subsistence harvest of marine mammals ranged between 2 and 66 percent of the total annual subsistence harvest for the community in the six years studied. Fish harvest ranged between 9 and 56 percent of the total annual subsistence harvest in those same years (Brower and Hepa 1998, Fuller and George 1999, Bacon, et al. 2009, ADF&G 2011). Nuiqsut harvesters have reported subsistence-use areas in the vicinity of Point Thomson for bowhead whales, seals, and waterfowl. Bowhead whales are the resource most intensively harvested by Nuiqsut residents in the project area. Whaling crews travel to Cross Island, which is northeast of Prudhoe Bay and approximately 11 to 12 miles from shore, and hunt from there. Nuiqsut residents do not report fishing in the project area; however, Nuiqsut residents harvest arctic cisco in the Colville River. These fish pass through the project area while migrating from the Mackenzie River delta in Canada to (See Appendix Q of the Draft EIS).

4.2.1. Potential Impacts

The analysis of impacts related to commercial and recreational fishing, including subsistence fishing, will include consideration of potential changes in the suitability of recreational and commercial fishing grounds as habitat for populations of consumable aquatic organisms. Discharges can also result in the chemical contamination of recreational or commercial fisheries. They may also interfere with the reproductive success of recreational and commercially important aquatic species through disruption of migration and spawning areas. The introduction of pollutants at critical times in their life cycle may directly reduce populations of commercially important aquatic organisms or indirectly reduce them by reducing organisms upon which they depend for food. Any of these impacts may be of short duration or prolonged, depending upon the physical and chemical impacts of the discharge and the biological availability of contaminants to aquatic organisms.

Sections 5.11, Marine Mammals; 5.12, Fish, Essential Fish Habitat, and Invertebrates, 5.18, Recreation; and 5.22 Subsistence and Traditional Land Use of the Draft EIS discuss the potential impacts of the Point Thomson Project on fish, fish habitats, invertebrates, marine mammals, and consumptive use of these aquatic organisms through recreational and subsistence fishing. Impacts to commercial and recreational fishing may occur if impacts to fish, invertebrate and marine mammal populations were to occur. The potential for these impacts are discussed in Sections 2.2, Aquatic Food Web, and 2.3, Other Wildlife. Impact analysis of the proposed discharge on recreational and commercial fishing will be included in this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

4.3. Water-Related Recreation (40 CFR 230.52)

Water-related recreation encompasses activities undertaken for amusement and relaxation. Activities encompass two broad categories of use: consumptive and non-consumptive. Sections 3.18, Recreation

and 3.22, Subsistence and Traditional Land Use of the Draft EIS describe water-related recreation in the project area.

Water-related recreation in the project area can be divided into two categories: recreational use of the project area by non-local residents and recreational use by local residents, often as a part of subsistence activities. As discussed in Section 4.2, Commercial and Recreational Fishing, non-local recreation in the project area is principally a backcountry and remote recreation experience. This is particularly true within the Arctic Refuge, on the eastern side of the Point Thomson project area. The Canning River, which forms the boundary between state land and federal land, is one of the main recreation corridors for river floaters and float hunters in the Arctic Refuge. Those using the river corridor may camp, hike, or hunt on state or refuge land. Besides the Canning River corridor, there is a coastal corridor of indeterminate width in which local residents travel by snowmobile or boat and camp for hunting and fishing, and in which visitors sometimes kayak. Occasional boats from Kaktovik with touring visitors also use the coastal corridor and may occasionally travel to the Point Thomson area. All non-local recreational use of the project area occurs at low levels.

Local residents typically do not label their activities in the general area as “recreation,” and many local residents interpreted recreation as “use of the Arctic Refuge by people who lived outside the local area (USFWS 1988).” There is, however, in western cultural terms a recreation component to traditional subsistence activities and camps. Scoping meetings for this project and the 2002 Point Thomson EIS effort did not generate comments from NSB residents about their own recreation, but did indicate that residents enjoy getting away from their usual home life for the quiet and change of pace of hunting and fishing camps, and that there was an appreciation of aesthetics of the land. As a result, a discussion of “recreation” by local residents is included in this section.

Local residents of the communities of Kaktovik and Nuiqsut use the project area for recreational purposes as they travel by boat for subsistence purposes. In addition to subsistence fishing, described in Section 4.2, residents travel by boat to harvest other important subsistence resources, such as caribou, in and around the project area.

4.3.1. Potential Impacts

The analysis of impacts related to water-related recreation will include consideration of the potential for impairment or destruction of the resources which support recreation activities. The disposal of dredged or fill material may adversely modify or destroy water use for recreation by changing turbidity, suspended particulates, temperature, dissolved oxygen, dissolved materials, toxic materials, pathogenic organisms, quality of habitat, and the aesthetic qualities of sight, taste, odor, and color.

Sections 5.18, Recreation and 5.22, Subsistence and Traditional Land Use of the Draft EIS describe impacts on water-related recreation in the project area. Impact analysis of the proposed discharge on water-related recreation will be included in this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

4.4. Aesthetics (40 CFR 230.53)

Aesthetics associated with the aquatic ecosystem consist of the perception of beauty by one or a combination of the senses of sight, hearing, touch, and smell. Aesthetics of aquatic ecosystems apply to the quality of life enjoyed by the general public and property owners. Sections 3.18, Recreation; 3.19, Visual Aesthetics; and 3.20, Noise of the Draft EIS discuss aesthetics in the project area.

The proposed Point Thomson Project is located in an undeveloped and uninhabited area within a few miles of the Arctic Refuge. Overall, the study area rated fairly high in visual quality based on seven characteristics such as landform, vegetation, and color. In particular, sensitivity was rated high in the Arctic Refuge and medium on most state land in the study area because most users of the area, both local and visitors, are thought to be fairly sensitive to visual changes and because the refuge is considered a special area. The Arctic Refuge is managed, in part for the preservation of the natural landscape, including natural visual environment and natural darkness. The State of Alaska does not manage its lands in the study area for visual resources.

The project area currently has low levels of noise from human activity. Existing sound levels during winter and summer conditions are dominated by natural sounds, atmospheric/meteorological phenomena, water features, and animals. Noise from human activities, other than currently permitted industrial activities, is largely absent from the ambient soundscape. Generally, sound levels in the coastal plains near surface water features are the loudest, while upland coastal plains areas without the influence of surface water features are the quietest.

4.4.1. Potential Impacts

The analysis of impacts to aesthetics in the project area will include consideration of potential changes in the beauty of natural aquatic ecosystems resulting from the degradation of water quality; creation of distracting disposal sites; encouragement of unplanned and incompatible human access; and the destruction of vital elements that contribute to the compositional harmony or unity, visual distinctiveness, or diversity of an area. The discharge of dredged or fill material can adversely affect the particular features, traits, or characteristics of an aquatic area which make it valuable to land owners and users. Activities which degrade water quality, disrupt natural substrate and vegetation characteristics, deny access to or visibility of the resource, or result in changes in odor, air quality, or noise levels may reduce the value of an aquatic area to private property owners.

Sections 5.19, Visual Aesthetics and 3.20, Noise of the Draft EIS describe impacts on aesthetics in the project area. Impact analysis of the proposed discharge on area aesthetics will be included in this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

4.5. Parks, National and Historical Monuments, National Seashores, Wilderness Areas, Research Sites, and Similar Preserves (40 CFR 230.54)

Parks, national and historic monuments, national seashores, wilderness areas, research sites, and similar preserves consist of areas designated under Federal or State laws or local ordinances to be managed for their aesthetic, educational, historical, recreational, or scientific value. The Arctic Refuge contains the Molly Beattie Wilderness, the only congressionally designated Wilderness area in proximity to the project area. The northwest corner of the Molly Beattie Wilderness is at the foot of the Sadlerochit Mountains 30 from the Point Thomson project area. The Arctic Refuge as a whole is discussed in Section 3.14, Arctic National Wildlife Refuge of the Draft EIS, and in Section 3.1, Sanctuaries and Refuges, above.

Cultural resources, such as pre-historic and historic sites, also exist in the project area. These include sites and materials of prehistoric Native American, historic European and Euro-American, and historic Iñupiaq origin such as cabin sites, camp sites, burial grounds, traditional subsistence harvest sites, and other traditional land use areas, landscapes, and place names. Between Endicott and Brownlow Point, there are

60 recorded cultural resources located in the proposed study area. Cultural resources in the project area are discussed in Section 3.21, Cultural Resources of the Draft EIS.

4.5.1. Potential Impacts

The analysis of impacts to parks, preserves, monuments, and other sites of importance will include consideration of potential modification of the aesthetic, educational, historical, recreational and/or scientific qualities thereby reducing or eliminating the uses for which such sites are set aside and managed. Sections 5.14, Arctic National Wildlife Refuge and 5.21, Cultural Resources of the Draft EIS describe potential impacts to the Arctic Refuge and cultural resources that my result from the proposed project. Impact analysis of the proposed discharge on area aesthetics will be included in this document after the public has had an opportunity to comment on the permit application and the Corps has published the Final EIS.

5. Subpart G: Evaluation of Dredged or Fill Material (40 CFR 230.60)

The purpose of the evaluation procedures and chemical and biological testing sequence outlined in this section is to provide the information needed to reach the factual determinations required by Proposed Disposal Site Determination in Appendix A, Section 6. To determine if additional chemical or biological testing is required, the Corps must consider available information regarding the proposed dredged and fill material, including prior evaluations, chemical and biological tests, scientific research, and past experience.

The Guidelines outline the decision-making procedure for this determination, which includes the following tests:

a) If the evaluation under Section B of Subpart G (below) indicates that the dredged and fill material is not a carrier of contaminants, then the required determination pertaining to the presence and effects can be made without testing. Dredged or fill material is most likely to be free from chemical, biological, or other pollutants where it is composed primarily of sand, gravel, or other naturally occurring inert material.

b) The extraction site shall be examined in order to access whether it is sufficiently removed from sources of pollution to provide reasonable assurance that the proposed discharge material is not a carrier of contaminants. Factors to be considered include, but are not limited to:

- Potential routes of contaminants or contaminated sediments to the extraction site, based on maps, aerial photography, or other materials that show watercourses, surface relief, proximity to tidal movement, private and public roads, location of buildings, municipal and industrial areas, and agricultural or forest lands;

- Pertinent results from tests previously carried out on the material at the extraction site, or carried out on similar material for other permitted projects in the vicinity. Materials shall be considered similar if the sources of contamination, the physical configuration of the sites and the sediment composition of the materials are comparable. Tests from other sites may be relied on only if no changes have occurred at the extraction sites to render the results irrelevant;

- Any potential for significant introduction of persistent pesticides from land runoff or percolation;

- Any records of spills or disposal of petroleum products or substances designated as hazardous under section 311 of the CWA (See 40 CFR 116);
- Information in Federal, State and local records indicating significant introduction of pollutants from industries, municipalities, or other sources, including types and amounts of waste materials discharged along the potential routes of contaminants to the extraction site; and
- Any possibility of the presence of substantial natural deposits of minerals or other substances which could be released to the aquatic environment in harmful quantities by man-induced discharge activities.

c) Where the discharge site is adjacent to the extraction site and subject to the same sources of contaminants, and the materials at the two sites are substantially similar, the fact that the material to be discharged may be a carrier of contaminants is not likely to result in degradation of the disposal site. In such circumstances, when dissolved material and suspended particulates can be controlled to prevent carrying pollutants to less contaminated areas, testing will not be required.

d) Even if the above tests lead to the conclusion that there is a high probability that the material proposed for discharge is a carrier of contaminants, testing may not be necessary if constraints are available to reduce the contamination to acceptable levels within the disposal site and to prevent contaminants from being transported beyond the boundaries of the disposal site. In this case, constraints must be acceptable to the permitting authority and the potential discharger must be willing and able to implement such constraints. However, even if tests are not performed, the permitting authority must still determine the probable impact of the operation on the receiving aquatic ecosystem. Any decision not to test must be explained in the Factual Determinations (Appendix A).

If, upon evaluation of the proposed dredge or fill material, the Corps determines that additional chemical, biological, and physical testing is required, testing guidelines are outlined under Section 230.61 of the Guidelines. If additional testing is not required, the Corps may use the information outlined above in making the factual determination required in Appendix A, Section 6, Proposed Disposal Site Determination.

Appendix C:

Actions to Minimize Adverse Effects (Subpart H)

Minimization includes actions which can be undertaken by the Applicant to minimize the adverse effects of discharges of dredged and fill material. Minimization measures are incorporated into the Corps' evaluation of the proposed project under the Factual Determinations (Appendix A) and Technical Evaluation Factors (Appendix B) as they have the potential to lessen adverse effects to waters of the U.S. and aquatic ecosystems. Minimization measures include, but are not limited to: actions concerning the location of the discharge; actions concerning the material to be discharged; actions controlling the material after discharge; actions affecting the method of dispersion; actions related to technology; actions affecting plant and animal populations; actions affecting human use; and other actions. Several examples of each of these action types are discussed below.

The Applicant has incorporated several measures to minimize impacts to waters of the U.S. into the design of Alternative B. All of these measures are outlined in the Applicant's Environmental Mitigation Report (ExxonMobil 2011d) and Final Department of the Army Permit Application (ExxonMobil 2011a). These measures are also discussed in detail in Section 4.4, Impact Avoidance, Minimization, and Mitigation of the Draft EIS and by resource section in Chapter 5, Environmental Consequences of the Draft EIS.

The Corps views the minimization measures outlined by the Applicant to represent a reasonable starting point for the development of the full scope of minimization measures that may be included in the evaluation of compliance with the Guidelines. However, the Corps has not yet determined if the Applicant's proposed minimization actions include all available, appropriate, and practicable measures. The Corps invites the public to comment on the current list of Applicant proposed minimization measures and to provide suggestions on additional minimization measures that may be practicable and appropriate to help reduce impacts to waters of the U.S. and aquatic ecosystems. A general list of example minimization measures have been grouped by type and are listed below. The list of examples is not exhaustive, but provides a starting point for consideration of the types of minimization measures that may be available to lessen potential impacts of the proposed project.

1. Actions concerning the location of the discharge (40 CFR 230.70)

The effects of the discharge can be minimized by the choice of the disposal site. Some of the ways to accomplish this are by:

a) Locating and confining the discharge to minimize smothering of organisms;

b) Designing the discharge to avoid a disruption of periodic water inundation patterns;

c) Selecting a disposal site that has been used previously for dredged material discharge;

d) Selecting a disposal site at which the substrate is composed of material similar to that being discharged, such as discharging sand on sand or mud on mud;

e) Selecting the disposal site, the discharge point, and the method of discharge to minimize the extent of any plume; and

f) Designing the discharge of dredged or fill material to minimize or prevent the creation of standing bodies of water in areas of normally fluctuating water levels, and minimize or prevent the drainage of areas subject to such fluctuations.

2. Actions concerning the material to be discharged (40 CFR 230.71)

The effects of a discharge can be minimized by treatment of, or limitations on the material itself, such as:

a) Disposal of dredged material in such a manner that physiochemical conditions are maintained and the potency and availability of pollutants are reduced.

b) Limiting the solid, liquid, and gaseous components of material to be discharged at a particular site; and

c) Adding treatment substances to the discharge material.

3. Actions controlling the material after discharge (40 CFR 230.72)

The effects of the dredged or fill material after discharge may be controlled by:

a) Selecting discharge methods and disposal sites where the potential for erosion, slumping or leaching of materials into the surrounding aquatic ecosystem will be reduced;

b) Maintaining and containing discharged material properly to prevent point and nonpoint sources of pollution; and

c) Timing the discharge to minimize impact, for instance during periods of unusual high water flows, wind, wave, and tidal actions.

4. Actions affecting the method of dispersion (40 CFR 230.73)

The effects of a discharge can be minimized by the manner in which it is dispersed, such as:

a) Where environmentally desirable, distributing the dredged material widely in a thin layer at the disposal site to maintain natural substrate contours and elevation;

b) Orienting a dredged or fill material mound to minimize undesirable obstruction to the water current or circulation pattern, and utilizing natural bottom contours to minimize the size of the mound;

c) Using silt screens or other appropriate methods to confine suspended particulate/turbidity to a small area where settling or removal can occur;

d) Making use of currents and circulation patterns to mix, disperse and dilute the discharge;

e) Minimizing water column turbidity by using a submerged diffuser system. A similar effect can be accomplished by submerging pipeline discharges or otherwise releasing materials near the bottom;

f) Selecting sites or managing discharges to confine and minimize the release of suspended particulates to give decreased turbidity levels and to maintain light penetration for organisms; and

g) Setting limitations on the amount of material to be discharged per unit of time or volume of receiving water.

5. Actions related to technology (40 CFR 230.74)

Discharge technology should be adapted to the needs of each site. In determining whether the discharge operation sufficiently minimizes adverse environmental impacts, the applicant should consider:

a) Using appropriate equipment or machinery, including protective devices, and the use of such equipment or machinery in activities related to the discharge of dredged or fill material;

b) Employing appropriate maintenance and operation on equipment or machinery, including adequate training, staffing, and working procedures;

c) Using machinery and techniques that are especially designed to reduce damage to wetlands. This may include machines equipped with devices that scatter rather than mound excavated materials, machines with specially designed wheels or tracks, and the use of mats under heavy machines to reduce wetland surface compaction and rutting;

d) Designing access roads and channel spanning structures using culverts, open channels, and diversions that will pass both low and high water flows, accommodate fluctuating water levels, and maintain circulation and faunal movement; and

e) Employing appropriate machinery and methods of transport of the material for discharge.

6. Actions affecting plant and animal populations (40 CFR 230.75)

Minimization of adverse effects on populations of plants and animals can be achieved by:

a) Avoiding changes in water current and circulation patterns which would interfere with the movement of animals;

b) Selecting sites or managing discharges to prevent or avoid creating habitat conducive to the development of undesirable predators or species which have a competitive edge ecologically over indigenous plants or animals;

c) Avoiding sites having unique habitat or other value, including habitat of threatened or endangered species;

d) Using planning and construction practices to institute habitat development and restoration to produce a new or modified environmental state of higher ecological value by displacement of some or all of the existing environmental characteristics. Use techniques that have been demonstrated to be effective in circumstances similar to those under consideration wherever possible;

e) Timing discharge to avoid spawning or migration seasons and other biologically critical time periods; and

f) Avoiding the destruction of remnant natural sites within areas already affected by development.

7. Actions affecting human use (40 CFR 230.76)

Minimization of adverse effects on human use potential may be achieved by:

a) Selecting discharge sites and following discharge procedures to prevent or minimize any potential damage to the aesthetically pleasing features of the aquatic site (e.g. viewscapes), particularly with respect to water quality;

b) Selecting disposal sites which are not valuable as natural aquatic areas;

c) Timing the discharge to avoid the seasons or periods when human recreational activity associated with the aquatic site is most important;

d) Following discharge procedures which avoid or minimize the disturbance of aesthetic features of an aquatic site or ecosystem; and

e) Selecting sites that will not be detrimental or increase incompatible human activity, or require the need for frequent dredge or fill maintenance activity in remote fish and wildlife areas.

8. Other actions (40 CFR 230.77)

a) In the case of fills, controlling runoff and other discharges from activities to be conducted on the fill;

b) When a significant ecological change in the aquatic environment is proposed by the discharge of dredged or fill material, the permitting authority should consider the ecosystem that will be lost as well as the environmental benefits of the new system.

Supplemental Documents

Exhibit A Request for Information Protocol

Exhibit B Cited RFIs

Exhibit C Applicant-submitted Information

The Point Thomson Environmental Impact Statement includes references to a variety of published and unpublished sources. This index provides the context and processes by which the third-party contractor obtained, verified, and used unpublished technical information in the preparation of the Point Thomson EIS.

1 Requests for Information

When it initiated alternatives development for the Point Thomson Environmental Impact Statement (EIS) process, the Corps identified the need for the third-party contractor to access unpublished technical information from the Applicant and other sources while maintaining the separation between the Applicant and the EIS writers. Subsequently, the Corps instituted the Request for Information (RFI) process using a standard protocol (Exhibit A) and tracking database. The Corps reviewed all requests, and Applicant-provided RFI responses were independently validated by internal or external experts. Table 1.1 summarizes all RFIs and their responses; those RFI responses that have been cited in the EIS or its supporting documentation are included in Exhibit B.

Table 1.1 RFI Submittals and Responses					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
1	Flaring	Clarification of "no routine flaring other than minor quantities of purge and pilot gas"	Applicant	A: Pilot and purge gas B: Response to follow-up questions	X
2	Refuse Management	Details of methods, equipment, and facilities used to control blowing trash	Applicant	A: Refuse management	
3	Visual Impacts	Height of communications tower at Central Pad as well as measurements of any new major building/object at Badami	Applicant	A: Communication tower details B: Representative communications tower photo C: Response to follow-up questions	
4	Visual Impacts	Detail on type of airport lighting for use in determining visual impacts in the project area	Applicant	Airport lighting details	X
5	Visual Impacts	Detailed description of staging areas at Point Thomson site or elsewhere, whether new or existing	Applicant	Staging areas descriptions	
6	Dismantle, Remove, and Restore (DR&R) Plans	Applicant lease requirements and any existing abandonment procedures or site restoration plans for end of production	Applicant	Applicant's plans for abandonment and applicable oil and gas lease requirements	
7	Brood-rearing Waterfowl and Shorebirds	Location, and habitats crossed by the above-the-ground water line from mine to Central Pad	Applicant	A: Brood-rearing waterfowl and shorebird habitat crossed by the water line B: Proposed temporary and permanent water line routes map	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
8	Oil and Hazardous Material Risks and Impacts Analysis	Copy (preferably electronic) of plans for response to spills of oil and hazardous materials at the Pt. Thomson site under current activities as an example of what EM plans for the proposed project	Applicant	A: Approved copy of Oil Discharge Prevention and Contingency Plan (ODPCP) B: Revised plan approval and certificate	
9	Water Quality	Year that samples were collected in Table 3-18	Applicant	Clarification of sample year	
10	Subsistence	Permission from MMS to analyze and create maps of forthcoming all resources use areas (1995-2006) for Nuiqsut collected by SRB&A in a previous MMS study	MMS	Resolved internally; no response correspondence	
11	Cultural Resources	Location of TLUI sites within project area	North Slope Borough		
12	Cultural Resources	Location of AHRS sites within project area	Office of History and Archaeology		
13	Recreation	Any quantitative numbers for human uses, or confirmation that no numbers or estimates exist, with an emphasis on recreational uses in the northwest portion of the Refuge	USFWS - Arctic National Wildlife Refuge	Telephone log: Seim	
14	Recreation	Any quantitative numbers for human uses, or confirmation that no numbers or estimates exist, with an emphasis on recreational uses	DNR	A: Telephone log: Reed B: Telephone log: Voss	
15	Oceanography	Storm surge levels used as basis for design	Applicant	Storm surge levels used for design	
16	Bathymetry	Ship and barge drafts, available bathymetric data, and expected temporal variability of bathymetric features	Applicant	Central Pad bathymetry drawing	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
17	Coastal Erosion	Wave, current, and storm surge criteria used for coastal erosion protection measures	Applicant	Design criteria	
18	River Flooding Potential	Analysis of river flooding potential and how it was considered in the design of possibly affected facilities	Applicant	Flooding potential	
19	Oil and Hazardous Materials	Liberty Development Project Environmental Assessment Document	MMS	Liberty Development Project EA	
20	Impacts to Soils and Permafrost	Information considered by the design team regarding subsurface conditions, soils, and permafrost	Applicant	Geology and geomorphology Information	
21	Sea Ice	Sea ice properties used for structural design	Applicant	Dock and waterfront facilities sea ice properties used for design	
22	Construction	Schedules for construction and barge offloading operations, including assumptions of access such as ice-free and open-water windows	Applicant	Module transportation plans for Alternative B	
23	Bulkhead design criteria	Surge and wave design criteria for both high and low bulkheads. Plan for disposal of dredged material	Applicant	Bulkhead design criteria	
24	Transportation and Logistics	"Point Thomson Modularization Study" per Project Description (p.8-4)	Applicant	A: Modularization study B: Sediment transport C: Material and equipment transport	
25	Emergency Response Boat Launch	Wave and surge design criteria for boat launch facilities	Applicant	Dock and emergency boat launch information	

Table 1.1 RFI Submittals and Responses (Continued)

RFI #	Title	Information Requested	Responder	Materials Received	Cited
26	Long-term Impacts of Waterfront Facilities	Evidence of designer's consideration of long-term direct and indirect effects of waterfront facilities	Applicant	List and explanation of littoral (shoreline) processed considered and analyzed	
27	Produced Water Characteristics	Produced water characteristics	Applicant	A: Produced water, condensate, and crude oil characteristics B: Characteristics of Point Thomson reservoir fluids	
29	Meteorology	2007 to 2009 meteorological monitoring data	Applicant	2007--2009 meteorological monitoring data	
30	Climate Change	Quantitative annual GHG emissions estimate for proposed project	Applicant	A: Emissions information B: GHG tables C: Construction and drilling emissions tables D: Operations emissions table	X
31	Local Employment	Local hire plan	Applicant	Local hire plan for proposed action	X
32	ER GIS data	GIS data used to create Figures 3-14 through 3-28 of the Environmental Report	Applicant	Resolved internally; no response correspondence	
33	Cultural Resources	Electronic or print copy of the reports referenced in the Point Thomson ER Bibliography	Applicant	List of cultural resources references	
34	Land Use/Land Management	Information on the State's management intent for lands and ocean waters surrounding Point Thomson	DNR	A: Point Thomson Leases B: PTU Agreements C: Telephone log: Perrin	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
35	Tourism and Recreation	ADF&G Any quantitative numbers for human uses, or confirmation that no numbers or estimates exist, with an emphasis on recreational uses.	ADF&G	No response received	
36	Waste Management	Integrated Waste Management Plan	Applicant	A: Explanation of waste management plan B: PTU Waste Management Plan Update C: ConocoPhilips Alaska Waste Disposal & Reuse Guide D: Nabors Green Book	
37	Anadromous Streams	The name (if named) and anadromous water body number of anadromous streams in the project area	Applicant	Assigned numbers to streams for use in the PDEIS	
38	Water Quality	The volume or percentage of water to be diverted from Stream B	Applicant	A: Summary of stream diversion calculations B: Water usage calculations table C: Excerpt from Corps Application D: Environmental Report figure 3-7	X
39	Water Quality: Hardness and Alkalinity	Any hardness, alkalinity, and turbidity that data that were collected	Applicant	A: Summary of hardness data B: Badami data table C: C-1 data table	
40	Filling of Ponds	Information on anticipated method for pad construction within partially-filled ponds, whether water bodies would be dewatered prior to filling, and where water would be pumped	Applicant	Pond fill approach summary	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
41	Water Quality: Discharge	Information referring to the discharge of domestic and hydrotest wastewater.	Applicant	Wastewater discharge plan	X
42	Plan of Operations and Associated Documents	Plan of Operations and other pertinent documents.	Applicant	A: Summary of supporting documentation B: Plan of Operations C: Badami lease D: ANGDA ROW application E: Liberty Mine Site Material Sale Contract F: Badami Mine Site Water Appropriation	
43	Spectacled Eider Survey Data	Survey area boundary and transect lines.	Applicant	A: Summary of ArcGIS data B: ArcGIS data files	
44	USFWS Arctic Coastal Plain Waterbird Survey Data and Density Maps	ArcGIS data files with metadata and report references SPEI data from USFWS – missing 2007 data, update with 2009 data.	USFWS	Request satisfied by response to RFI 43	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
45	Terrestrial Mammals	ArcGIS files including summarized with metadata and reference to project reports ADF&G Calving Locations from 2003-2009 (ER has 1990-2002 CAH), number of collared cows available for sampling all years, estimated (modeled) population size by year (TCH, CAH, PCH)	Agencies	A: Memorandum summarizing data received B: Caribou Management Report for Porcupine Herd (ADF&G 2006--2008) C: Caribou Management Report for Central Arctic Herd (ADF&G 2006--2008) D: Wolf Management Report (ADF&G 2005--2008) E: Map of muskoxen sitings within 30 miles of Point Thomson F: Badami and Point Thomson area muskoxen observations map (1995-2003)	
46	Geology, Geomorphology, Soils and Permafrost	References, documentation, and general questions related to geology and geomorphology	Applicant	Detailed response to question regarding soils	X
48	Barge Facilities and Operations	Information regarding barge facility operations	Applicant	Detailed response to questions regarding barge offloading	
49	Facilities, Infrastructure, and Operational Components	The total, complete facilities, infrastructure, and operational components involved with full field development; including hydrates, oil, and natural gas production	Applicant		

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
50	Interactions with Other Area Projects	The range of interactions between Applicant's Point Thomson project and Shell's offshore development projects The range of interactions and involvements between Applicant's Point Thomson project and other nearby on-shore developments such as Sourdough	Applicant		
51	Fish References	Copies of "gray" literature referenced in ER	Applicant	RFI not approved by Corps; no materials received	
52	Natural Gas Production Information	All available information concerning full development of project as requested below	Applicant		
54	Stream Names	A list of standard names to be used in the EIS to refer to all streams from Shaviovik River east to Staines River	Applicant	A: Summary of provided information B: Stream designations table	
55	Protection Against Coastal Erosion	Proposed long-term permanent shoreline erosion protection at the barge facility and methods of shoreline and nearshore water resource protection	Applicant	A: Summary of erosion protection and shoreline protection methods B: Preliminary logistics summary C: Marine module offloading typical barge link for barge bridge (image) D: Marine module offloading typical 3-barge configuration (image) E: Marine module offloading first grounded barge (image)	X
56	Vegetation Mapping: Pipeline Corridor (Bullen Point)	A specific reference for the vegetation mapping along the pipeline corridor (Bullen Point)	Applicant	Verification of sources for vegetation mapping and feature classes	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
57	Emissions	Emissions associated with drilling, construction, and operational activity	Applicant	A: Summary of potential emissions and methodology B: 2007-2009 emissions metadata table C: Revision to initial submittal D: Revision to 2007-2009 emissions metadata table	X
58	Onshore Ice Roads	Methods of ground-based visual observations of the gathering and export pipelines	NA--RFI not approved	NA	
59	Clarification on Proposed Sea or Onshore Ice Roads Connecting Deadhorse to Point Thomson	Request for clarification of the various ice roads between Deadhorse and Point Thomson	NA--RFI not approved	NA	
60	Clarification on Proposed Stream Crossings	The method of crossing the unnamed creek between F Creek and Creek 18a and the tributary of B Creek	Applicant	Confirmation that creeks only flow during high water	
61	Visual Impacts: 3D Modeling	Overall site plan and engineering grade contours of site, surroundings, detailed plans and as-built drawings of pad components and pipeline components, and any existing 3D model information of man-made structures	Applicant	A: Detailed plans B: Multiple datasets for modeling purposes	
62	Airstrip Development	High-level "literature" review of recent innovations and applicability to Point Thomson, including ROM costs for aircraft and airstrips, historic use of C-130s for worst-case scenarios, and temporary airstrip construction techniques	HDR	Summary of literature review findings	X

Table 1.1 RFI Submittals and Responses (Continued)

RFI #	Title	Information Requested	Responder	Materials Received	Cited
63	Bottomhole Reservoir Characteristics	A range of pad locations that would meet the project's development requirements and supporting information Confirmation that the existing east-pad bottomhole location is fixed and no reasonable alternative locations exist The maximum reach possible for attaining this/these target(s) considering existing drilling technology, geology, and reservoir characteristics	DNR	A: State confirmation of reasonableness of Applicant's well pad locations needed to reach bottomhole targets B: Approximate extent of reservoir with bottom hole target map	X
64	Compression and Reinjection	Detailed description of the collocational constraints of processing and reinjection facilities	HDR	A: Separated compressor station alternative concept discussion B: Relocation of Point Thomson compression to Badami alternative concept discussion C: Summary memorandum discussing parts A and B	X
65	Compression Specs	Comparison of detailed specifications on reciprocal and centrifugal compressors to evaluate practicability and environmental impacts and potential for mitigation	HDR	A: General comparison of compression types and requirements B: Augmented comparison of compression types and requirements C: Investigation of the existence of in-service centrifugal compressors sized commensurate with the compression requirements of Point Thomson	X

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
66	Applicant Compression Specs	Detailed specifications for reciprocal compressors to evaluate practicability and environmental impacts	Applicant	General description and specifications for Point Thomson reciprocal compressor	
67	Footprint for Grind and Inject Facilities	Approximate footprint needed for grind and inject facility and associated waste storage facilities	Applicant	A: Description of current waste storage needs and G&I sizing B: Applicant UIC Permit Application C: Amendment to initial submittal	
68	Applicant Ice Roads	Performance standards and specifications for "standard" ice road construction for anticipated logistical ground support, heavy-duty ice roads for module transportation, and ice pad/airstrip that could support anticipated air support	Applicant/DNR/HDR	Discussion of justification for ice road type (sea or tundra) selection and standard ice infrastructure construction and maintenance requirements	
69	Applicant UIC well	When Applicant intended to bring UIC well online	Applicant/DNR - AOGCC	Verification that yes, the Application intends to bring the UIC well online as part of the proposed action	
70	Gravel and Water Sources	Evaluation of potential gravel and water source locations in the project area that could meet project needs under different alternative scenarios	Peak	Description of gravel and water availability in the Point Thomson area	
71	Automated Production Facility	Review of existing automated gas-cycling production facilities, including requirements, constraints, limitations, and/or risks for operating an oil and gas operation with an automated production facility	HDR	Discussion of remote operation possibilities	X
72	Insulated Ice Pads	Materials and methods are used to construct insulated ice and insulated gravel pads, longevity of an insulated ice and insulated gravel pad, engineering restrictions/constraints for insulated ice and insulated gravel pads, and cost of constructing an insulated ice/gravel pad	Peak	Explanation of materials, methods, longevity, constraints, and impacts of multiseason insulated ice and gravel pads	

Table 1.1 RFI Submittals and Responses (Continued)

RFI #	Title	Information Requested	Responder	Materials Received	Cited
73	Power Capacity Badami	Power generation facilities currently at Badami, the total energy output capacity of the facilities, and current energy use and baseload/excess generation capacity at Badami	HDR	Discussion of Badami power generation capacity estimates	X
74	Large Mammal Survey Boundaries	GIS data for large mammal surveys of the Badami and Bullen Point to Staines River survey areas as presented in Figure 1 of Noel and Cunningham (2003)	Applicant	Explanation that requested information was provided by a contractor and that the Applicant did not have the requested information	
75	No-Action Alternative	Applicant's level of activity and presence at Point Thomson if the federal action resulting from the EIS is to not issue a Corps permit, and description of potential activity that could occur at Point Thomson if Applicant was not allowed to place fill in association with the proposed project (or any major activity that would require fill in the Point Thomson area)	Applicant	A: Summary of attached materials • Barge route • Ice road as-builts • Barging and helicopter B: Addendum to initial transmittal • Datasets • Barging and helicopter routes	X
76	Bullen Point Road Information	All available data related to the State's Bullen Point Road project and State information on the CH2M Hill effort that investigated other road alternatives from the Endicott spur to the east	Don Perrin	A: Bullen Point RTA B: Bullen Point cultural resources information C: Bullen Point meteorological and hydrological information D: RTA economics whitepaper	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
77	Project Emissions and Met Data 2007-09	Information on the applicability of New Source Performance Standards (40 CFR 60) and National Emission Standards for Hazardous Air Pollutants (40 CFR 61, 63) that may be subject to the stationary source or equipment used during drilling/construction and operations. Pre-control device emissions for any of the equipment used at the stationary source that has a control device Plans, if any, to store any hazardous materials subject to the Chemical Accident Prevention Provision/Risk Management Plan (40 CFR Part 68).	Applicant	Detailed response to questions in the RFI submission	X
78	Construction Impacts	Description of standard Alaska North Slope construction equipment and methods to be used in the construction of Point Thomson development components Temporary construction footprints for all components if different than final component footprints	Applicant	Summary of North Slope construction methods	X
79	Copy of RFI Database from the 2002 EIS Effort, with Associated Requests and Recipient Responses	A copy of the RFI database with active links to associated documents and submittals, in the event that information developed as part of the previous effort would be useful; thereby reducing duplicative effort and maximizing efficiency	Applicant	A: Index of 2002 RFIs B: RFI response log	
80	Existing Transportation Network	Transportation footprint for all access to and within Point Thomson	NA: RFI not approved	NA

RFI #	Title	Information Requested	Responder	Materials Received	Cited
81	Vegetation Mapping Reference Points	The ground reference data point collected for the "Vegetation and Land Cover Map of the Proposed Badami Oil Development Area" vegetation mapping effort conducted by LGL Alaska Research Associates, Inc. (1995), for BP Exploration (Alaska) Inc.	Lynn Noel, LGL	GIS data points	
82	Spectral Noise Emissions for Processing/ Compression/Power Generation Equipment	Detailed information on all equipment used in processing, compression, and power generation facilities, including equipment related to the proposed 3-phase separation process that is proposed to occur at the CPF, solar turbines, and any other noise emitting infrastructure.	North Slope Borough	A: Summary of noise modeling methodology and assumptions B: Datasets transmitted to noise subject matter expert (digital files available upon request)	
83	Nabors 27E Drill Rig Noise Report	A copy of the report that details noise levels measured at various locations in and around the Nabors 27E drill rig	Applicant/John Neason (Nabors)	Bulkhead design criteria	
84	Logistics for Construction, Monitoring, and Training Efforts	Types of ongoing or regularly-scheduled activities might occur throughout the life of the project that would require additional transportation of people and equipment not covered in the preliminary logistics plan	Applicant	Summary of logistics, training, and monitoring for the proposed action	X
85	Feasibility of Locating Processing Components in the Gravel Mine	Feasibility study on the possibility of locating the processing/compression facility in the excavated gravel mine as proposed in component 3c	HDR	Assessment of the feasibility of in-mine facilities	
86	Lighting and Design Mitigation to Prevent Impacts to Birds	Description of facility lighting and any design mitigation developed to prevent interference with migration or bird collisions	Applicant	Explanation that lights will be shaded and directed to minimize impact	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
87	Noise Analysis: Gravel-related Equipment and Timeline	Detailed information on the equipment used to develop pads, roadways, the airstrip, etc. under the proposed Point Thomson project, including how many of each type will be used, where they will be used and timelines for their use (e.g., how long if only for initial construction, or how long each year and what time of year)	Applicant	A: Summary of preliminary construction equipment plans B: Tables 1-9 detailing the equipment required for each phase of construction	
88	Project Sequencing for Construction, Drilling, and Operations	Timeline for activities associated with construction, drilling, and operation	Applicant	A: Summary of Gantt chart and expected sequencing B: Gantt chart of potential project sequencing	
89	Detailed Demobilization Plans	Detailed demobilization plans and timeline in the event of the 404(b)(1) permit application denial by the USACE under a No Action Alternative scenario	Applicant	Summary of demobilization, referencing information in RFI 75	
90	Large Oil Spills	Contact Information (phone, email) for Evans, T. (referenced as a personal communication on page 4-189 of the 2009 Environmental Report). Detail on the causes, response actions and time frame, and impact assessment of the spill, preferably in written form that Applicant/URS used for the brief discussion in the ER	Applicant	Provided contact information and hyperlink to ADEC's reports regarding the 2006 GC-2 Oil Spill	
91	Maximum Oil Spill Possible from Gathering Lines and from Export Lines	Worst case release of “product” (defined as liquids that may include produced water, crude oil, gas condensate, etc.) from each of the gathering lines and export pipeline The maximum volume of product that could be lost from a pipeline at or near the East and West Pads and the Central Pad for all alternatives	Applicant	Summary of requested information for proposed action	X

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
92	Condensate Production Rate	Develop an analysis of condensate production rate vs. time for various gas reinjection rates	DNR-DOG, Applicant	RFI in progress	
93	Design and Logistics of Transportation Components	Design alternatives available for transportation and logistics components and optimal uses, advantages, and limitations of each Maintenance required for both full size and light-duty gravel roads, and gravel airstrips in winter on the North Slope	Peak	Expert feasibility assessment for light-duty gravel road, ice pads, insulated ice pads, and ice airstrip extensions	X
94	Buried Pipelines Feasibility Review	Thorough examination of existing information on the feasibility of placing both gathering and export pipelines in or along roads	Applicant	Technical Brief 7, provided in Exhibit B of this index	
95	Oil Rim Viability	Data or substantive text discussing the likelihood that the oil rim will be viable for production, definition of "viability," and plan for the East and West Pads if the oil rim is not viable	Applicant	Discussion of the information to be provided by drilling of the East and West pad wells, and next steps if oil rim is not viable	X
96	Fish Exclusion Structure in Diversion Channel	Confirmation whether a fish exclusion device will be installed on the inlet structure to the reservoir in order to prevent fish from entering the reservoir	Applicant	Confirmation that installation of a fish screen at the diversion channel is not planned	
97	Clarifications on Conceptual Scenario for Alternative 3A	Clarification for the Applicant's assumptions on ice and gravel road locations, water and gravel factors, and quantities for infrastructure.	Applicant	Detailed response to each request	X
98	Ice Road Construction from Endicott Spur to Badami	Applicant's assumptions regarding construction of an ice road from Endicott Spur to Badami during operations	Applicant	Detailed response including comments and rational for building the Endicott -to-Badami ice road	
99	NA	RFI ended prior to submittal for approval	NA		
100	Air Quality—Emissions Updates	Additional information regarding criteria pollutant emissions, fugitive dust, and GHG emissions data provided in updates to RFIs 57 and 30	Applicant	A: Partial response to request for updates B: Emissions updates	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
101	Spill Response Plans and Automated Technologies	Information regarding the Applicant's Supervisory Control and Data Acquisition (SCADA) system that remotely measures changes in pressure and volume to detect pipeline leaks Copies of Applicant's Spill Prevention, Control, and Countermeasure Plan (SPCC) and Facility Response Plan (FRP) as well as an updated Oil Discharge Prevention and Contingency Plan (ODPCP) for the proposed project Maximum sizes of storage tanks for diesel, gasoline, methanol, antifreeze, and other materials in each storage area	Applicant	Automated Spill Response Technologies and Spill Response Plans	
102	Reports and Spatial Data for 2010 Field Studies	Applicant reports and spatial data associated with 2010 field investigations conducted to support the Point Thomson Project (when they are finalized) Information about the availability of 2010 field investigations that may have been conducted for other oil and gas companies in the Point Thomson EIS	Applicant	A: 2010 Point Thomson Nearshore Fish Study B: Point Thomson Project 2010 Hydrology Report Note: these reports, if cited in the text of the EIS, were cited as reports and not as responses to this RFI	
103	Methods for Designing and/or Maintaining Culverts to Ensure Free Water flow During Spring Breakup	Design and/or maintenance methods ExxonMobil will use to ensure that cross drainage culverts allow water flow during breakup (i.e., are not blocked with ice)	Applicant	Justification for not considering ice blockage in culvert design, and assurance of maintenance during breakup.	

Table 1.1 RFI Submittals and Responses (Continued)					
RFI #	Title	Information Requested	Responder	Materials Received	Cited
104	GIS Data of Watershed Boundaries with Metadata	Shapefile or geodatabase, including data and metadata, of watershed boundaries delineated for the project to estimate watershed volume for calculation of spring breakup flow volumes and rates Methods used to determine the watershed boundaries	Applicant	GIS files	
105	Badami Generator Air Emissions	Clarification regarding whether generator emissions were included in inventories, how inventories might be impacted by design change in size of generator, conditions under which generator might be used, and whether the generator would be included in the permit application	Applicant	A: Detailed response B: Table of potential emission calculations and permit applicability analysis for the Badami generator	
106	Dredged Materials Disposal Location	A specific location for placement and disposal of dredged materials, as well as the basis for selection of the disposal site and evidence that the disposal location avoids and minimizes impacts to coastal resources	Applicant	A: Location and rationale for the placement of dredged spoils B: Figures featuring the dredged spoils area C: Shapefiles for the dredged spoils area	X
107	Borehole Geotechnical Data	Discussion of geotechnical data for mine resources, trends/lack thereof in the geotechnical profiles in the project area, specific data available, and information about overburden	Applicant	A: Detailed response B: Figure showing borehole locations C: Borehole logs	

Table 1.1 RFI Submittals and Responses (Continued)

RFI #	Title	Information Requested	Responder	Materials Received	Cited
111	Updated Air Quality Data	Emission calculation spreadsheets for both modeled and non-modeled pollutants, including updates to criteria pollutants, GHGs, and fugitive emissions Emissions sources and modeling data, including AERMOD input and output files, contour plots, summaries of contour plots, diversion model protocols, and PSD permitting plan		A: Narrative response to request 1 B: Fugitive emissions memorandum C: Point Thomson Air Quality Modeling and Impact Assessment (Draft) D: Emission source inventory spreadsheet E: HAP emissions spreadsheet F: Emission unit inventory spreadsheet	X
112	Drilling Mud Composition	A breakdown of the physical and chemical characteristics with percent volume, concentration or other appropriate measure of the components including any chemicals that could be considered hazardous waste or hazardous materials		No response received	

2 Applicant-submitted Information

In addition to RFIs, the Applicant provided supplemental materials as requested to support the alternatives development process. These materials included technical briefs (see Table 2.1) that provided general North Slope engineering information, such as the requirements for burying pipelines in tundra, to explanations of project-specific considerations such as compression type and well-pad locations.

Table 2.1 Technical Briefs

Tech Brief #	Title	Description
1	Well Pad Locations	Identifies the Applicant's current understanding of the reservoir and the relationship between pad location and accessibility of the reservoir.
2	Centrifugal Compressors	Highlights the difference between centrifugal and reciprocal compression, and the conditions required to operate each.
3	Analysis of Proposed "Light Duty" Road	Clarifies the differences in thickness between standard and light-duty gravel roads.
5	Buried Pipelines on the North Slope	Analyzes the challenges of thaw settlement, surface drainage impacts, and other potential issues associated with heated pipelines buried in tundra on the North Slope
6	Runway Design	Justifies the size of the proposed runway based on the intended maximum capacity required
7	Buried Pipelines in Gravel Roads on the North Slope	Addresses the specific concerns of installing heated pipelines within gravel roads; supplemented by the *Assessment of the Below-ground Trans-Alaska Pipeline Following the Magnitude 7.9 Denali Fault Earthquake*

Because the Applicant's proposed action was the result of two years of engineering, the level of detail provided in Alternative B was significantly greater than the detail developed for other alternatives in Chapter 2. To support an even comparison, the Corps asked the Applicant to develop conceptual scenarios for each alternative that described the amount of engineering required to design the alternative; the duration and requirements for construction; and any logistical implications of the strategies for construction, drilling, or operations in each alternative.

The full text of both the technical briefs and conceptual scenarios are included in Exhibit C

Exhibit A

Request for Information Protocol

POINT THOMSON
PROJECT EIS

Request For Information Protocol

USACE
Post Office Box 6898
Elmendorf AFB, AK 99506

February 2010

1 Introduction

The function of the request for information (RFI) database is to capture and track project inquiries related to development of the Point Thomson Project EIS. Information requested through an RFI may include such things as details related to project design; data presented in the Environmental Report; requests for new or additional baseline information; or other project-related information or documentation. The purpose of this protocol is to define the process by which RFIs are initiated and tracked to completion.

It is anticipated that RFIs will primarily flow from HDR, the USACE, or a Cooperating Agency to ExxonMobil (the Applicant). Some requests may also be made by the USACE, HDR, or the Applicant to a Cooperating Agency. Irrespective of who initiates the RFI, the same process will apply. For simplicity in this protocol, the *Requestor* is the person that initiates the RFI and the *Recipient* is the person who ultimately receives and responds to the RFI.

The RFI database will be managed by HDR and stored on ProjectWise.

2 RFI Process

RFIs will generally follow a five-step process to completion as outlined below and illustrated in Figure 1:

Step 1 – RFI initiated and approved

Step 2 – RFI forwarded to recipient

Step 3 – Response to RFI developed

Step 4 – Information reviewed by Requestor for adequacy

Step 5 – RFI deemed complete

2.1 RFI Initiated and Approved

RFIs can originate at any time during the development of the EIS. Activities that will likely elicit RFIs include the data gap analysis, bi-weekly Coordination Team Meetings, Scoping activities, and development of the Preliminary EIS. RFIs will be initiated by a Requestor completing and submitting an RFI Initiation Form (Appendix A). This form includes fields that capture critical details such as:

- person making the request (Requestor)
- person or organization responding to the request (Recipient)
- date of request
- proposed timeline for completion
- project feature requiring additional information
- details of the information requested
- relevance to the EIS
- request priority
- whether requested information should be included in the Administrative Record

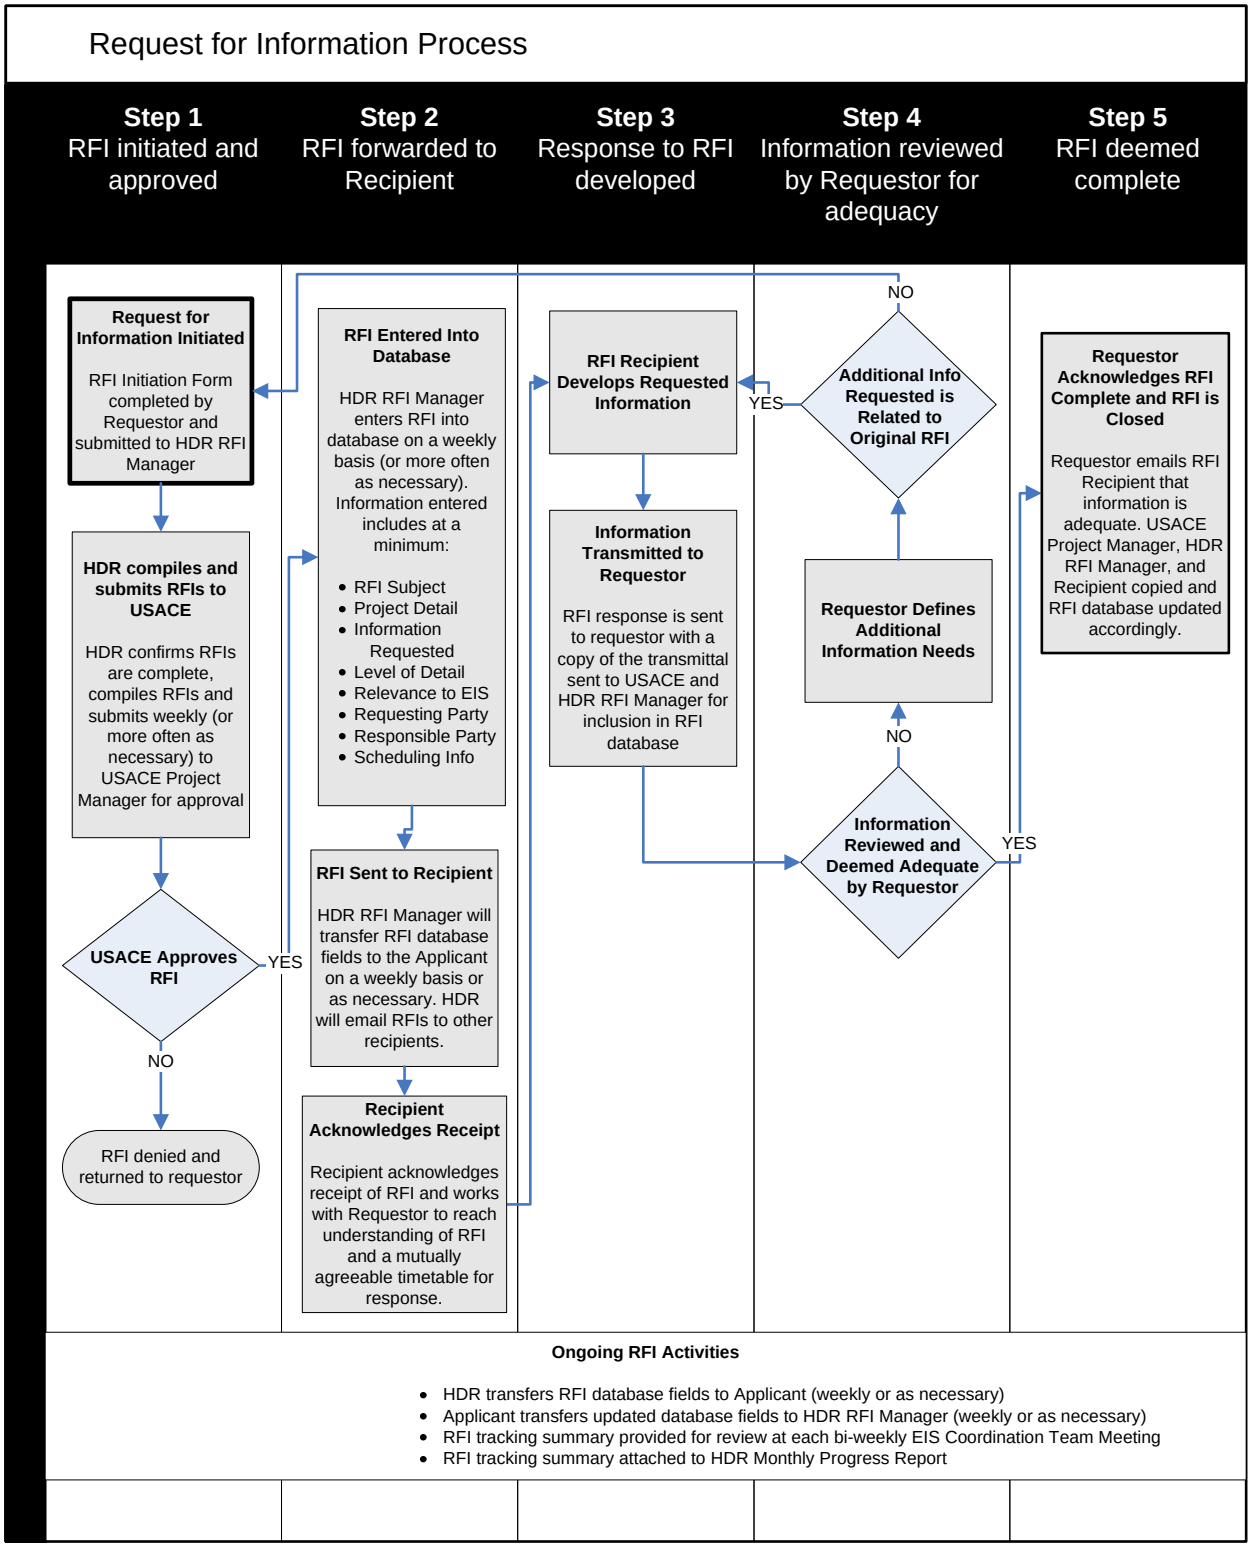

Figure 1. Request for Information process flow diagram.

Completed RFI Initiation Forms will be forwarded (in person or by email) to the HDR RFI Manager, Michael Allwright. Emails shall contain "RFI" in the title block. RFIs will be reviewed for completeness and compiled electronically. On a weekly basis (or as necessary to facilitate a timely process), RFIs will be forwarded to Julie McKim, USACE Project Manager, for approval and inclusion in the database.

Some RFIs may be deemed by HDR to be minor in nature (e.g., will not require a significant effort from the Recipient) and such RFIs may be transmitted without USACE endorsement directly to the Recipient with a copy to the USACE.

2.2 RFI Forwarded to Recipient

Once an RFI has been approved, the HDR RFI Manager will forward the RFI, along with a unique identification number, to the appropriate designated single point of contact (SPOC), which are provided below for each organization.

Organization	Single Point of Contact
HDR	Michael Allwright
Applicant	Peter Hanley
USACE	Julie McKim
EPA	Ted Rockwell
USFWS	Louise Smith
ADNR	Don Perrin

It is anticipated that the majority of RFIs will be requests to the Applicant. Approved RFIs will be transferred electronically to the Applicant's SPOC on a weekly basis (or as otherwise necessary to ensure the timely transfer of requests) along with an export file of RFI database fields.

In the event that RFIs are requested of other EIS Coordination Team members, the RFI will be emailed to the Recipient identified in the RFI Initiation Form.

2.3 Response to RFI Developed

Upon receiving an RFI, the Recipient shall confirm their receipt via email within one (1) business day of transmittal. Confirmation receipts shall be sent by email to the HDR RFI Manager. "RFI" and the unique identification number shall be included in the email's title.

The Recipient will then have three (3) business days to review the request and ensure that:

- they understand exactly what is being requested; and
- they agree with the priority and timeline requested.

If the Recipient has questions about the RFI (e.g., needs more detail on information being requested or challenges the timeframe of request) the Recipient shall include their questions or comments in a response to the HDR RFI Manager, with a copy to and USACE Project Manager. If necessary (e.g., for complex

issues or data requests), a meeting can be called to clarify details of the RFI. In the event that agreement cannot be reached on how best to resolve differences, the USACE Project Manager will arbitrate and provide ultimate direction, as necessary.

The *Date Requested* entry on the RFI form will correspond to the date the RFI was sent to the Recipient. The *Requested Due Date* will be the date that the Requestor identifies as the date they anticipate receipt of the information from the Recipient. This will represent the due date unless the Recipient challenges or seeks clarification of the RFI. In these cases, the Recipient may propose a due date, which will correspond to the *Proposed Due Date*, pending endorsement by the HDR RFI Manager and/or the USACE Project Manager.

Completed RFI deliverables shall be transmitted by the Recipient via email directly to the Requestor; emails shall contain "RFI" in the title. Deliverables shall be accompanied by a transmittal and both shall be copied to the HDR RFI Manager and USACE Project Manager for inclusion in the database and project files.

2.4 Requestor Reviews Information for Adequacy

Upon receipt of transmittal, the Requestor shall review the information and determine the adequacy of the response. The Requestor shall respond to the transmittal within five (five) business days by emailing their determination to the Recipient, HDR RFI Manager, and the USACE Project Manager.

2.5 RFI Determined Complete or Additional Information Requested

If the RFI response is deemed adequate, the HDR RFI Manager will inform the recipient via email, with a copy to the USACE Project Manager, and update the database to reflect that the RFI is complete.

In the event that the RFI response is determined not adequate, the Requestor shall provide the Recipient with a description of the additional information required for completion of the RFI. In the event of disagreement on the information gap, the parties may convene a meeting to clarify details. In the event that agreement cannot be reached on how best to resolve the matter, the USACE Project Manager will arbitrate and provide ultimate direction, as necessary.

The process will return to Step 3 if the additional information is deemed similar enough to the original RFI. If the necessary information is too dissimilar to the original scope of the RFI, the original RFI will be deemed complete and a new RFI will be opened.

3 Monitoring RFI Status

RFI status will be reviewed by the EIS Coordination Team on a regular basis as part of the bi-weekly meetings. Status review of the RFI database will be included as an agenda item at each meeting, and the updated status report will be provided to the meeting attendees for their review at least one day prior to the regularly scheduled meetings.

The Applicant will provide weekly database field updates to the HDR RFI Manager. Database fields will be transferred via a secure .ftp site. These weekly updates will ensure timely tracking of RFI progress and accurate reporting for the bi-weekly meetings.

Information Needed:	Clarification of “no routine flaring other than minor quantities of purge and pilot gas.”
Level of Detail:	Details on consistency and visibility of “pilot and purge” flame.

Comments and Rationale:

Level of Priority: ☐ Low ☒ Standard ☐ High ☐ Extreme
Time Sensitivity: ☐ Low ☒ Standard ☐ High

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 1 - Flaring

Clarification of 'no routine flaring other than minor quantities of purge and pilot gas'. Details on consistency and visibilities of pilot and purge flame.

Date of RFI: 1/8/10

Date of Response: 1/22/10: Response to Follow-up Question: 2/9/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

From: Peter Hanley, EIS SPOC

Response

The pilot and purge flames are not considered flaring and they operate continuously for safety reasons. Flaring is a non-routine event and involves larger volumes of gas than the pilots and purge gas. A description of the circumstances involved with flaring and the associated volumes of gas are provided in Section 9.1.3 of the Project Description.

The following description of the pilot and purge flames is typical because the flare system and equipment will be designed and procured later in the project.

Visibility

The HP and LP pilots and purge gas use produced natural gas.

The HP and LP pilots have a blue flame and are not visible during the daytime. The pilot flame may be approximately 18" long.

HP and LP purge flames are roughly the same size and have a yellowish flame . With wind the flame may be 1 ft high and extend 10 ft horizontally and with no wind it may be a couple of feet in diameter and extend 8 ft vertically.

The HP flare stack will not exceed a height of 150 feet above ground surface and the LP flare will not exceed a height of 75 feet above ground surface. The actual height will be determined as the Project's design proceeds. The pilots are attached at the top of the stacks, so pilot heights are the same as the stacks.

The current estimates of flare pilot and purge gas flow rates are shown below and are subject to change as the design proceeds.

	HP Flare	LP Flare
Pilot gas	300 scfh (1)	200 scfh (1)
Purge gas	1500 scfh	100 scfh
(1) Pilots typically require about 100 scfh per tip. The project has assumed three pilot tips for the HP flare and two pilot tips for the LP flare.		

Follow-up Question

(a) [this] specifically mentions that the blue flame is not visible in daylight but does not address the visibility of the other flames. Left as-is, I would assume that the yellow flames are visible in daylight and all flames are visible in darkness, and that there is no screening. (b) Also, there is a question whether there is any other lighting (e.g. for aircraft safety) on the flare stacks.

Response

(a) The yellow flames will be visible in the daylight and all flames will be visible in darkness.
(b) Amount of lighting for flare stack will be determined in detailed engineering later this year.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 1 - Flaring

Clarification of 'no routine flaring other than minor quantities of purge and pilot gas'. Details on consistency and visibilities of pilot and purge flame.

Date of RFI: 1/8/10

Date of Response: 1/22/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

Detail on Type of Airport Lighting **-** Size, frequency of use, and type of lighting for use in determining visual impacts in the project area.

Date of RFI: 1/8/10

Date of Response: 1/29/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

From: Peter Hanley, EIS SPOC

Response

The Point Thomson Airstrip will be located approximately 3 miles from the coast. The Airstrip is being designed to comply with applicable FAA guidelines and regulations. There would be approximately three fixed-wing flights (three takeoffs and three landings) per day, and 1-2 helicopter flights during major construction for a period of 2 years. It is estimated that this level of air traffic will be reduced by 50% to support ongoing operations. The approach, runway, and apron lights (described below) are turned on whenever the airport is in use. All other lighting is turned on at dusk and turned off at dawn.

The following lighting details are excerpted from Aviation and Navigation Aids Design Specification, USPT-WP-CSPDS-071007 December, 2009 - Revision B.

High Intensity Runway Edge Lighting (HIRL)
High intensity runway edge lights (FAA type L-862) will be installed approx. every 200 feet, 85 feet from runway centerline. The lights will use 200W halogen lamps and mounted on 24" high conduit painted FAA aviation yellow. The thresholds will have eight type L-862E high intensity lights of the same configuration as the edge lights. The runway lights are 2 feet above the runway.

Medium Intensity Taxiway/Apron Edge Lighting (MITL)
Medium intensity taxiway edge lights (FAA type L-861T) will be installed along both of the taxiways and around the aircraft apron. The lights will be located 10 feet back from the operating edge of the apron. The lights will be spaced per the applicable FAA A/C. The lights will use LED lamps and mounted on 24" high, conduit painted FAA aviation yellow. The apron lights are 2 feet above the apron.

Medium Intensity Approach Lighting System (MALSR)
Both runway 5 and runway 23 will have a 2,400 foot medium intensity approach lighting system with runway alignment indicator lights (MALSR). The approach lights are 1 foot above the runway elevation extending 2400 feet off each runway end. The MALSR consists of 13 elevated lights at the threshold and seven light bar assemblies spaced

every 200 feet out to 1400 feet from the threshold. The system continues with five single strobe lights spaced every 200 feet starting 200 feet past the light bar and ending 2400 feet from the threshold. The strobe lights and light bars are located on frangible towers mounted to galvanized steel plates supported by VSMs. All lights and strobes point out from the runway. There are over 63 steady burning lights and five strobe lights on each MALSR (a total of 2 MALSRs).

Airport Beacon
An FAA L-802A airport beacon will be located on top of the passenger module. It will be controlled by the lighting control panel in the control shelter. It will come on automatically at night.

Precision Approach Path Indicators (PAPI)
FAA type L-880 Four box precision approach path indicators will be installed approx. 900 feet towards mid field from each runway threshold. The light boxes are spaced 30 feet apart starting 125 feet from centerline to 215 feet from center line. Each light box will be mounted on 2" GRS conduit mounted to frangible couplings that are bolted to a galvanized steel plate welded to a VSM.

Primary Wind Cones
Two FAA type L-807 primary wind cones will be located approx. 300 feet toward mid field from each threshold. They will be approx. 400 feet from the centerline. The wind cones will be 12 feet high with a 36" diameter. The windsock will be internally lit with LED lamps. There will be an L-810 LED obstruction light on top of the wind cone.

Lighted Roadway Cautionary Signs
Signs with flashing red lights will be provided 400 feet from extended centerline on the road between the central pad and the east pad. The lights will be operated when an aircraft or helicopter is on approach.

Helicopter Parking Area Elevated Perimeter Lighting
Elevated perimeter lighting will be provided around the perimeter of the helicopter parking area. The flood lights will be mounted on stems and angled down across the parking area.

Building Mounted Lighting
Each of the buildings on the airport (six buildings distributed around the airport property) will have exterior mounted lights over each door to the building.

Obstruction Lighting
Every building, windcone, RVR tower, communications tower, and all other equipment over four feet high will have a red obstruction light on it. The obstruction lights have (2) 120W lamps, each with a red lens. There will be over 35 obstruction lights distributed around the airport property.

RFI 30 – Greenhouse Gas (GHG) Emissions

Quantitative annual GHG emissions estimate for proposed project.

Date of RFI: 1/21/10

Date of Response: 2/12/10

Date of Revision: 8/10/10

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Response

Point Thomson project greenhouse gas (GHG) emissions of carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) result from combustion of fuel gas, diesel, and municipal solid waste by stationary and mobile equipment. Methane emissions from natural gas extraction and natural gas liquids processing are negligible because the process occurs in a closed system. A summary of the total estimated GHG emissions from the Point Thomson Project is:

Total Estimated GHG Emissions from Point Thomson (tones/yr)

Project Phase	CO_2	CH_4	N_2O	CO_2 Equivalent*
Construction	339,378	14	3	340,451
Production	318,485	10	2	319,188

*CO_2 Equivalent (CO_2e) is the total global warming impact and includes CO_2 emissions and the equivalent CO_2 global warming potential impact from CH_4 and N_2O. Per the 40 CFR 98 calculation requirements, CH_4 has a global warming impact 21 times greater than CO_2. Per the 40 CFR 98 calculation requirements, N_2O has a global warming potential of 310 times greater than CO_2.

GHG Emission Estimation Methodology

The methods for estimating GHG emissions for fuel combustion sources are applied in accordance with the guidance provided in Subpart C of the Mandatory Reporting of Greenhouse Gases Rule (40 Code of Federal Regulations Part 98) for Tier 1 units. The CO_2, CH_4, and N_2O emission estimates are calculated for all stationary and mobile equipment on an individual basis using Equation C-1 from 40 CFR 98.

$$CO_2, CH_4, N_2O = 1 \times 10^{-3} * Fuel * HHV * EF \text{ (Equation C-1)}$$

Where:

CO_2, CH_4, N_2O = mass of GHG, tonnes per year
Fuel = Volume of fuel combusted per year
HHV = Default high heat value of the fuel from Table C-1, 40 CFR 98
EF = Fuel-specific default emission factors from Table C-1, 40 CFR 98

The per-equipment volume of fuel combusted is determined by assuming continuous operation at the equipment's maximum capacity, or according to any federally enforceable restrictions limiting the unit's annual operation.

The default factors From Table C-1 of 40 CFR 98 used to estimate GHG emissions from the Point Thomson project are:

Default Factors Used to Estimate GHG Emissions from Point Thomson

Fuel Type	High Heat Value	CO_2 Emission Factor	CH_4 Emission Factor	N_2O Emission Factor
Distillate Fuel Oil No. 2	0.138 MMBtu/gallon	73.96 kg CO_2/MMBtu	3.0×10^{-3} kg CH_4/MMBtu	6.0×10^{-4} kg N_2O/MMBtu
Pipeline Natural Gas	1.028×10^{-3} MMBtu/scf	53.02 kg CO_2/MMBtu	1.0×10^{-3} kg CH_4/MMBtu	1.0×10^{-4} kg N_2O/MMBtu
Municipal Solid Waste	9.95 MMBtu/short ton	90.7 kg CO_2/MMBtu	3.2×10^{-2} kg CH_4/MMBtu	4.2×10^{-3} kg N_2O/MMBtu

The production and construction emission unit inventory used for estimating GHG emissions are based on preliminary inventory that has not yet been finalized. The mobile equipment and non-road engine inventory is based on the projected requirements during project construction. All emission unit inventories are subject to change as detail design work proceeds.

The GHG emission calculation assumptions and details are provided in Tables 1 through 9.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 30 – Greenhouse Gas (GHG) Emissions

Quantitative annual GHG emissions estimate for proposed project.

Date of RFI: 1/21/10

Date of Response: 2/17/10

To: Tim Gallagher HDR Project Manager, Scott Zitka

From: Peter Hanley, EIS SPOC

Response

Point Thomson project greenhouse gas (GHG) emissions of carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) result from combustion of fuel gas, diesel, and municipal solid waste by stationary and mobile equipment associated with the drilling and production phases of the project. Methane emissions from natural gas extraction and natural gas liquids processing are negligible because the process occurs in a closed system. A summary of the total estimated GHG emissions from the Point Thomson Project is:

Total Estimated GHG Emissions from Point Thomson (tonnes/yr)

Project Phase	CO_2	CH_4	N_2O	CO_2 Equivalent*
Drilling/Construction	199,398	7.1	1.3	199,961
Production	306,144	9.7	1.6	306,834

*New federal regulations at 40 CFR 98 provide for calculation of a CO_2 Equivalent (CO_2e) total which includes CO_2 emissions and the the CO_2 equivalent from CH_4 and N_2O. Per the 40 CFR 98 calculation, the CH_4 equivalent is considered 21 times greater than CO_2 and the N_2O equivalent is considered 310 times greater than CO_2.

GHG Emission Estimation Methodology

The methods for estimating GHG emissions for fuel combustion sources are applied in accordance with the guidance provided in Subpart C of the Mandatory Reporting of Greenhouse Gases Rule (40 Code of Federal Regulations Part 98) for Tier 1 units. The CO_2, CH_4, and N_2O emission estimates are calculated for all stationary and mobile equipment on an individual basis using Equation C-1 from 40 CFR 98.

*CO_2, CH_4, N_2O = 1 x 10^{-3} * Fuel * HHV * EF (Equation C-1)*

Where:
CO_2, CH_4, N_2O = mass of GHG, tonnes per year
Fuel = Volume of fuel combusted per year
HHV = Default high heat value of the fuel from Table C-1, 40 CFR 98
EF = Fuel-specific default emission factors from Table C-1, 40 CFR 98

The per-equipment volume of fuel combusted is determined by assuming continuous operation at the equipment's maximum capacity, or according to any federally enforceable restrictions limiting the unit's annual operation.

The default factors From Table C-1 of 40 CFR 98 used to estimate GHG emissions from the Point Thomson project are:

Default Factors Used to Estimate GHG Emissions from Point Thomson

Fuel Type	High Heat Value	CO_2 Emission Factor	CH_4 Emission Factor	N_2O Emission Factor
Distillate Fuel Oil No. 2	0.138 MMBtu/gallon	73.96 kg CO_2/MMBtu	3.0 x 10^{-3} kg CH_4/MMBtu	6.0 x 10^{-4} kg N_2O/MMBtu
Pipeline Natural Gas	1.028 x 10^{-3} MMBtu/scf	53.02 kg CO_2/MMBtu	1.0 x 10^{-3} kg CH_4/MMBtu	1.0 x 10^{-4} kg N_2O/MMBtu
Municipal Solid Waste	9.95 MMBtu/short ton	90.7 kg CO_2/MMBtu	3.2 x 10^{-2} kg CH_4/MMBtu	4.2 x 10^{-3} kg N_2O/MMBtu

The drilling/construction stationary emission unit inventory used for estimating GHG emissions is based on the inventory currently operating at the Point Thomson Project. The production stationary emission unit inventory used for estimating GHG emissions is based on a preliminary inventory that has not yet been finalized. The mobile equipment and non-road engine inventory is based on the projected requirements during project construction, but was conservatively for both the drilling/construction and production GHG emission estimates. All emission unit inventories are subject to change as detail design work proceeds.

The GHG emission calculation assumptions and details are provided in Tables 1 through 14.

Table 1. Point Thomson Production Facility
GHG Emission Summary

Pollutant	Potential GHG Emissions	
	During Construction[1]	During Production
CO_2	339,378 tpy	318,485 tpy
CH_4	14 tpy	10 tpy
N_2O	3 tpy	2 tpy
CO_2e^2	340,451 tpy	319,188 tpy

Notes:

1. Includes mobile equipment and construction non-road engine emission units.
2. CO_2e is the CO_2 equivalent emissions applying the global warming potential for each GHG from Table A-1, 40 CFR 98.

					Total Potential CH_4 Emissions for All Emission Units		12.293 tpy	9.873 tpy

Notes:
1. Distillate No. 2 default high heat value: 0.138 MMBtu/gallon
2. Pipeline natural gas default high heat value: 1.03E-03 MMBtu/scf
3. Municipal solid waste default high heat value: 9.85 MMBtu/short ton

Table 5. Point Thomson Production - Stationary Equipment Potential N_2O Emissions

Emission Unit No.	Identification	N_2O Emission Factor Reference		Maximum Fuel Consumption	Maximum Operation During Construction	Maximum Operation During Operation	Potential N2O Emissions During Construction	Potential N_2O Emissions During Operation
Production Emission Units

64	130 Ton Crane	Table C-2, 40 CFR 98	6.00E-04 kg N_2O/MMBtu	14,400 gal/yr	0.001 tpy
			Total Potential N_2O Emissions for All Emission Units		0.247 tpy

Notes:

1. Distillate No. 2 default high heat value: 0.138 MMBtu/gallon

Table 1. Point Thomson Drilling/Constuction GHG Emission Summary

Pollutant	Potential GHG Emissions
Stationary Equipment	
CO_2	171,785 tonnes/yr
CH_4	6.0 tonnes/yr
N_2O	1.1 tonnes/yr
Mobile Equipment and Construction Non-Road Engines	
CO_2	27,613 tonnes/yr
CH_4	1.1 tonnes/yr
N_2O	0.2 tonnes/yr
CO_2e	199,961 tonnes/yr

Note:
1. CO_2e is the CO_2 equivalent emissions applying the factors for each GHG from Table A-1, 40 CFR 98.

Table 2. Point Thomson Drilling - Stationary Equipment Emission Unit Inventory

Emission Unit No.	Identification	Description	Maximum Fuel Consumption	Maximum Capacity	Maximum Operation
1	Industrial Combustion KLG-42	Drill Rig Boiler #1	30.0 gal/hr	4.2 MMBtu/hr	8,760 hr/yr
2	Industrial Combustion ML-63P	Drill Rig Boiler #2	45.0 gal/hr	6.3 MMBtu/hr	8,760 hr/yr
3	Iron Fireman C-240-F-4.2	Drill Rig Pipeshed Tioga Air Heater #1	30.0 gal/hr	4.2 MMBtu/hr	8,760 hr/yr
4	Iron Fireman C-240-F-4.2	Drill Rig Pipeshed Tioga Air Heater #2	30.0 gal/hr	4.2 MMBtu/hr	8,760 hr/yr
5	Industrial Combustion ML-63P	Drill Rig Support Boiler #1	45.0 gal/hr	6.3 MMBtu/hr	8,760 hr/yr

Table 10. Point Thomson Production GHG Emission Summary

Pollutant	Potential GHG Emissions
Stationary Equipment	
CO_2	278,531 tonnes/yr
CH_4	8.6 tonnes/yr
N_2O	1.4 tonnes/yr
Mobile Equipment and Non-Road Engines	
CO_2	27,613 tonnes/yr
CH_4	1.1 tonnes/yr
N_2O	0.2 tonnes/yr
CO_2e	306,834 tonnes/yr

Note:
1. CO_2e is the CO_2 equivalent emissions applying the factors for each GHG from Table A-1, 40 CFR 98.

Table 11. Point Thomson Production - Stationary Equipment Emission Unit Inventory

Emission Unit No.	Emission Unit Identification	Emission Unit Description	Fuel Type	Maximum Fuel Consumption	Maximum Capacity	Maximum/Allowable Operation
Production Emission Units

Response to Request for Information

RFI 31 – Local Employment

Local Hire Plan or Economic Opportunity Plan as referenced in Section 11.1 of the Project Description.

RFI Level of Detail: Expected numbers, types, and durations of jobs intended to be filled by North Slope Borough residents. Information is needed for both construction and operation phases of project

Date of RFI: 1/21/10

Date of Response: 2/18/10

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Response

The Point Thomson Project schedule currently calls for a multi-year construction period to commence in 2011, once all necessary permits have been achieved. Construction is scheduled for completion by the end of 2014. Following are the projected employment levels, for the primary functional categories for each year during construction. These figures do not include ExxonMobil management and professional support in Anchorage and Houston:

Calendar Year	Slope Construction	AK Fabrication	Operations
2011	50-100	125-200	5-10
2012	600-800	100-150	5-10
2013	300-450	50 -150	50-80
2014	50-150	25-50	60-90

Drilling-related positions will vary significantly depending upon drilling activity. During periods of drilling activity employment is estimated to be between 150-180 personnel.
North Slope residents and Alaskan Natives are encouraged to apply for jobs in all categories. Commencing in 2011 available job openings will be posted via the State of Alaska/Savaat Center in Barrow and on the Barrow Public access television channel. To help facilitate employment opportunities for North Slope residents, Point Thomson contractors are encouraged to “hire, train and retain” Native residents. Ten of the project’s primary contractors, as well as several educational and training institutions, participated in an October 2009 Kaktovik Job Fair sponsored by ExxonMobil. This is an event that ExxonMobil will sponsor in Kaktovik annually during the fourth quarter to encourage local employment and training success. In addition, internships, apprenticeships and other skills education programs will be supported by ExxonMobil to offer young adults an opportunity to experience possible career choices.

ExxonMobil has awarded significant contracts to subsidiaries of the Native Corporations of

Kaktovik, Kaktovik Iupiat Corporation, and of Nuiqsut, Kuukpik Corporation. In 2009, the most recent year data is available, North Slope resident hire for these two contracts totaled approximately 20 residents of the North Slope Borough. ExxonMobil will continue to seek contracting opportunities with these firms, and other partners and subsidiaries of North Slope corporations.

Seasonal hire for area residents represents an additional opportunity for local employment on the Point Thomson Project. Depending upon project activity, positions for Marine Mammal Observers, Subsistence Advisors and Polar Bear Monitors all contribute necessary local expertise to guide project activities as well as offering a seasonal work schedule that compliments subsistence hunting, fishing and whaling activities.

Long-term employment for the project operations phase will require facility operators, mechanical technicians, electrical technicians and instrument technicians. ExxonMobil intends to work with the University of Alaska and technical college programs to recruit graduates with these skills. ExxonMobil will work to identify candidates from the North Slope Borough who have aptitude and interest to receive the required training and scholarships to assist in this training.

ExxonMobil is currently finalizing staffing plans for the Point Thomson Project operations including numbers of employees needed and the timing for recruiting and hiring activity. Estimates provided herein may change as the Project progresses through engineering and management reviews. The number of company employee positions for ongoing (steady state) operations is estimated to be approximately 20 on a rotating basis; this would require a total of 40 personnel. In addition to the company positions, there will be opportunities with contractors to be equipment operators, and to fill camp maintenance positions, and other positions that support the direct operations. The total number of onsite company and contractor positions combined is estimated to be approximately 55 for long term operations. ExxonMobil will encourage contractors to make a concerted effort to inform local residents of employment opportunities.

The seasonal hire of area residents for Marine Mammal Observers, Subsistence Advisors, and Polar Bear Monitors will continue into the operations phase, as will job fair participation. The Company will focus on hiring qualified candidates from Alaskan communities which will include North Slope residents throughout all phases of the Project.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI No. 38 – Water Quality

Information Needed:

How much (volume) water is going to be diverted from Stream B? Is it going to be a percentage or an exact volume?

Level of Detail:

Need to know a range, actual amount, or percentage to determine how this will affect downstream water chemistry as well as fish and fish habitat.

Date Received 2/25/10

Date of Response: 3/16/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

From: Peter Hanley, EIS SPOC

Response

The allowable diversion from Stream B would be up to 80% of the breakup flood volume during the first 3 years and less than 20 million gallons per year thereafter as shown in Table 1. Actual diversion volumes will depend on the breakup flood magnitudes. For example, if the Year 1 flood volume is moderately large, then smaller diversions will be necessary in years 2 and 3.

Table 1. Estimated Stream B Breakup Flood Diversion Volumes

	Year 1	Year 2	Year 3	Year 4+
Desired Stream B Diversion Volume (Million Gallons)	168-402	167-317	7-164	7
Probability of Meeting Desired Diversion Volume	75%-99%	90%-99%	99%-100%	>99.99%
Diversion Percentage of Total Breakup Flood Volume	64%-80%	27%-80%	1%-78%	<5%

Diversion estimates in Table 1 are based on an assumed minimum breakup flood volume of 210 million gallons, which is estimated to have a 99% chance of being exceeded in a given year. Assuming that 80% of this volume may be diverted yields a

diversion volume of 168 million gallons with a 99% probability of being met during Year 1, as shown in Table 1.

Discussion and Background:

The subject of this RFI #38 “Stream B” , Figure 3-7 on the November 2009 Environmental Report, is the stream identified as “Stream 24B” on the 10-19-2009 project permit drawings, Sheet 42 of 55 (copies attached for reference), which flows past the existing C-1 Pit and proposed Gravel Mine. Water will be diverted from Stream B into the C-1 Pit and the reclaimed Gravel Mine (after mining is completed) to replace water withdrawals for ice roads and work pads, drilling needs and domestic/camp uses, and to provide initial filling of the reclaimed Gravel Mine.

Preliminary “rough order of magnitude” estimates of project total water demand are in the range of 70 million gallons during the first year of project construction, 180 million gallons during the second year, and 20 million gallons per year thereafter. In addition, approximately 400 million gallons will be required to fill the reclaimed Gravel Mine, depending on its final size and reclamation plan, making the total combined water demand for Years 1-3 approximately 670 million gallons. Some of the required water (and ice aggregate) will be obtained from suitable lakes and existing pit lakes along proposed ice road and pipeline routes and from natural runoff into the Gravel Mine and C-1 Pit. Total combined withdrawals of over 500 million gallons will be required from Stream B during Years 1-3, however, to fill the Gravel Mine and supply project needs in the vicinity. A conceptual water balance used to estimate required Stream B diversions is shown in Table 2. Water supply/demand scenarios and gravel mine storage relationships are provided in Attachments A1 and A2.

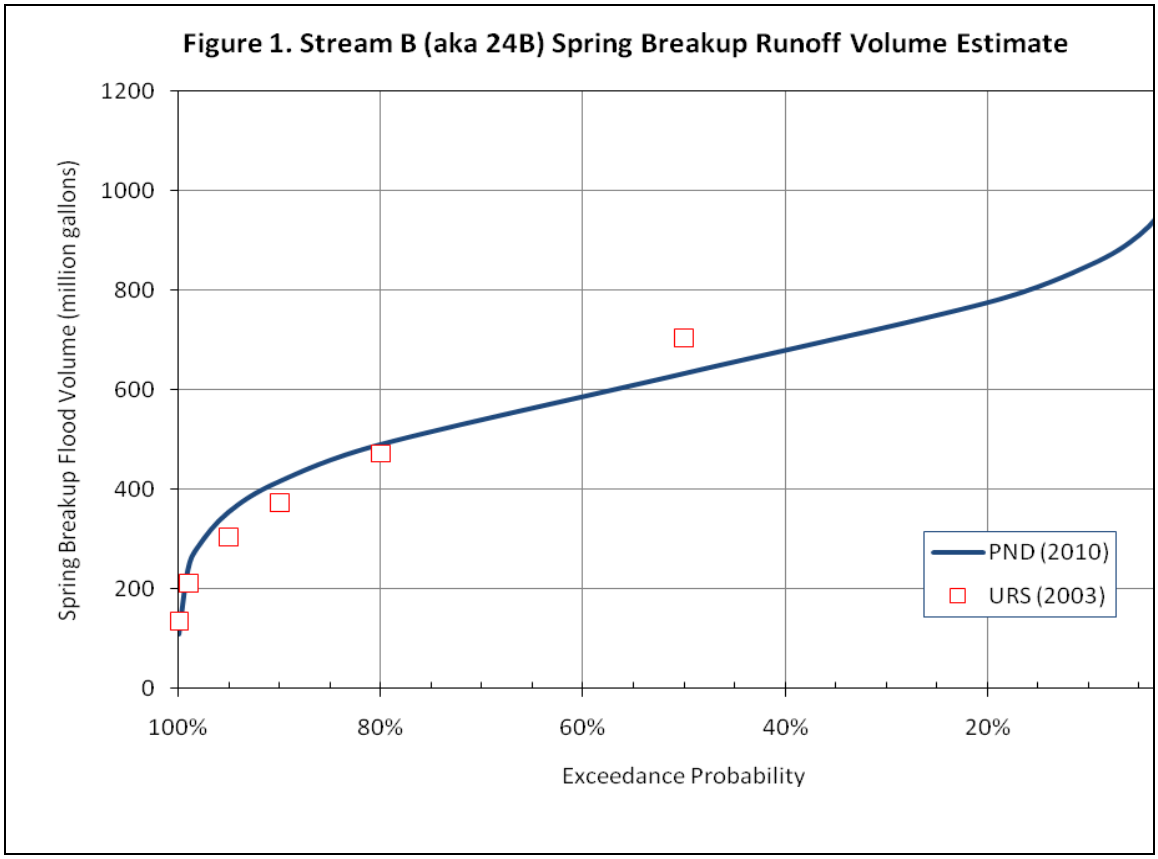

Table 2. Conceptual Water Balance Plan (Rough Order-of-Magnitude)

Demand/Supply	Water Volumes (Million Gallons)			
	Year 1	Year 2	Year 3	Year 4+
Water Demand				
C-1 Pit	15	2	2	2
Gravel Mine	0	102-178	18	18
Other Pit/Lake Sources	55	0-76	0	0
Total Water Withdrawals	70	180	20	20

Total Water Supply	236-470	180-330	20-177	20

Initial filling and replenishment of the Gravel Mine and C-1 Pit will come from natural runoff into these reservoirs and diversion of spring/early summer breakup flows from Stream B. Natural recharge from the relatively small areas that would naturally drain into C-1 Pit and the Gravel Mine is estimated to be approximately 13 million gallons in an average year, although the actual amount will vary considerably.

Water withdrawals from Stream B would be made only during spring breakup and early summer when high flows from annual snow runoff are occurring. PND used annual snow accumulation and runoff data from Kane et al. (2009) to estimate breakup flood volumes. PND's estimates correlate well to estimates derived independently using a different method (URS Feb 28, 2003), as shown in Figure 1. This estimated breakup flow is 630 to 700 million gallons during an average year (mean annual event), meaning that there would be a 50% chance of that amount being exceeded in a given year. The estimated 90% and 99% exceedance probability breakup flood volumes are 370-420 and 210-240 million gallons, respectively. Thus, we estimate that there is a 99% chance each year of exceeding a breakup flood volume of between 210 and 240 million gallons.

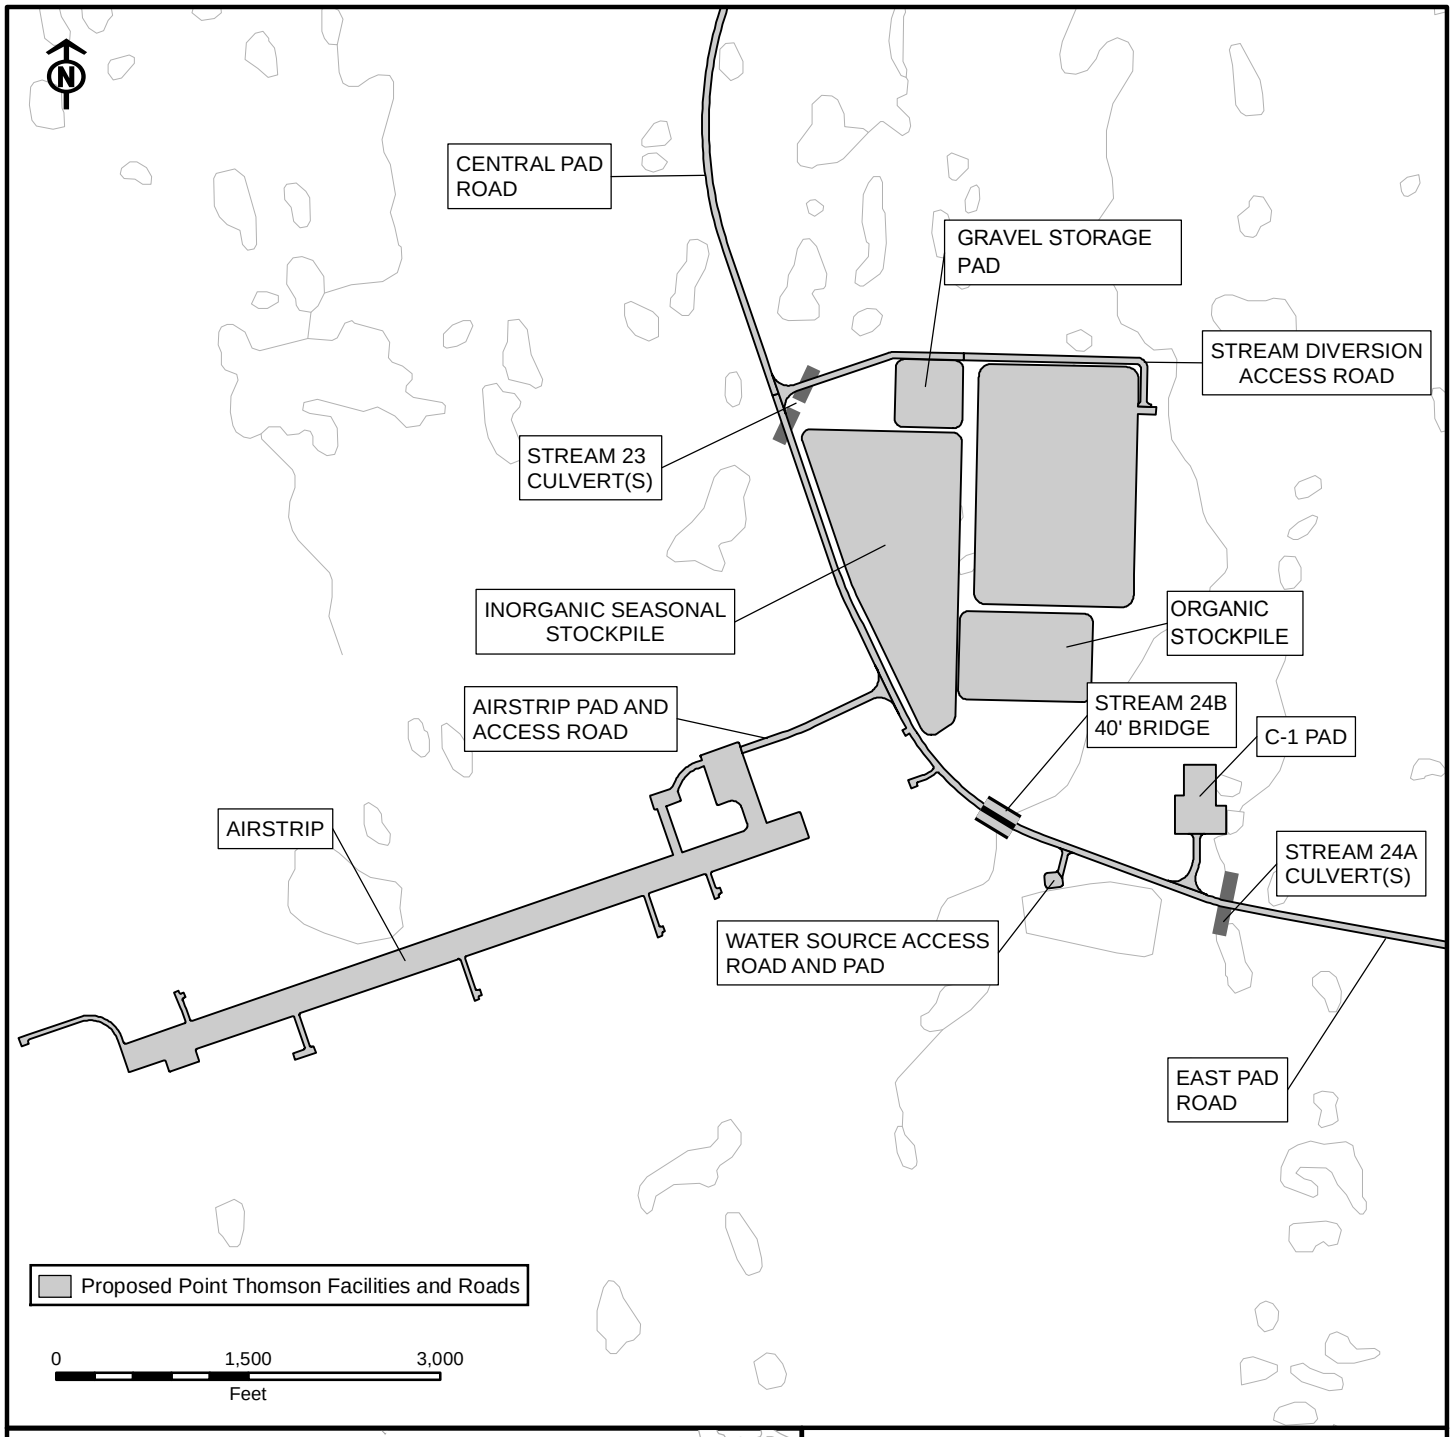
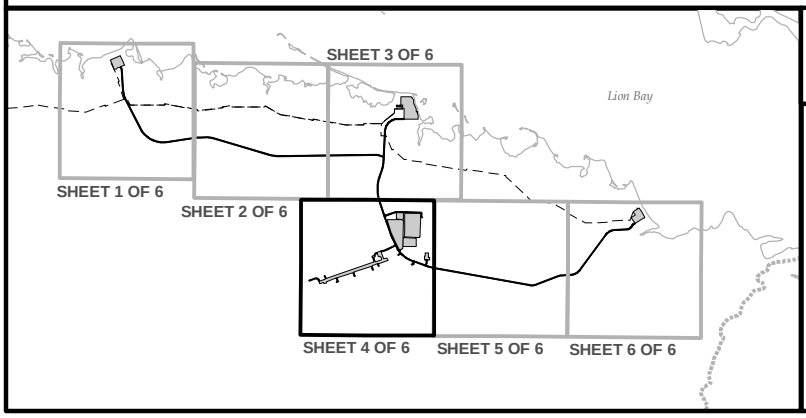
Notes



(1) C-1 Pit and Gravel Mine volumes based on 2009 surveys and computations by PND. C-1 Pit volume and allowable withdrawal shown is more than allowed in TWUP A2008-124, which only allowed 9.38 million gallon withdrawal based on 30% of water storage volume under 5-ft of ice. New C-1 values by PND are based on same 30% under 5-ft ice criteria, but using new (2009) pit survey data.



(2) Gravel Mine allowable withdrawal is assumed to be 100% of water volume under 5-ft of ice during critical Year 2, but can be much less in subsequent years. Assume maximum withdrawals not to exceed 20% of total mine volume after Year 2. If fish take up residence, no more than 15% of volume beneath 7-ft of ice may be withdrawn or 30% of volume under 5-ft of ice if only nine spine stickleback and Alaska blackfish are

(3) Stream B (aka Stream 24B/24A) breakup flood volumes were estimated independently using different methods by PND (2010) and URS (2003), with similar results. During first 2 or 3 years, diversions of up to 80% of breakup flood volumes are required to fill the reclaimed Gravel Mine, depending on the size of the breakup floods. It is very unlikely that large diversions will be required in Year 3.

(4) Other pit/lake sources will include other lakes or mine sites along pipeline or ice road routes. Withdrawals may consist of either water or ice aggregate.

RFI No. 41 – Water Quality

Referring to the discharge of (a) domestic wastewater and (b) hydrotest water:

- *Where will discharge take place?*
- *Where will the end of the pipe be?*
- *At what depth?*
- *What will the frequency of discharge be?*
- *What will be the volume of waste be?*
- *What form of treatment will the waste stream go through?*

Received 2/25/10

Date of Response: 3/26/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

From: Peter Hanley, EIS SPOC

Response

(a) Waste Water Discharge

Where will discharge take place? During construction, the treated domestic wastewaters will be discharged to either the tundra or to the bay (marine waters) near the Central pad in accordance with general permits to be issued by the State of Alaska later this year. Discharge would be covered under ADEC General Permit AKG-57-0000 (Small Publicly Owned Treatment Works (POTW) and Other Small Treatment Works Providing Secondary Treatment of Domestic Sewage and Discharging to Freshwater) for a tundra discharge, or AKG-57-1000 (Small Publicly Owned Treatment Works (POTW) and Other Small Treatment Works Providing Secondary Treatment of Domestic Sewage and Discharging to Marine Water) for a marine discharge. These permits are currently expired but are expected to be reissued by ADEC in 2010 with similar or identical conditions.

During long term operations, the normal disposition of the treated domestic wastewater will be to inject down an approved subsurface disposal well (Class I industrial), commingled with other facility generated wastewaters. Should a disposal well outage or injection pump outage occur, the treated domestic wastewater will be discharged via a divert line to a similar location and under the same permit coverage as described in the paragraph above.

Where will the end of the pipe be? The outfall for both construction and the divert line used during long term operations will be at a location where the discharge will naturally drain away from the pad or construction camp if tundra discharge is chosen. The end of pipe for a marine discharge will be east or north of the pad.

At what depth? The divert line(used during equipment outage) will be a heat traced line

supported on piles/VSM's and/or timbers, where required, and discharged above grade or above sea level at a point high enough to prevent ice from forming and blocking further discharge.

What will the frequency of discharge be? Continuous during construction. During long term operations, discharge to tundra or marine waters would only occur when the injection well is not available for disposal.

What will be the volume of waste be? It is estimated there will be approximately 18,240 gallons per day of discharge during operations, however, as noted in #1 wastewater will be disposed of in a disposal well except during equipment outages.

During the construction phase the maximum wastewater volumes discharged are estimated to be 40,000 gallons per day (coinciding with construction of the export Pipeline), and a maximum of 20,000 gallons per day for 2 to 3 month periods over the remainder of the construction phase.

What form of treatment will the waste stream go through? The ADEC permit will require secondary treatment. The permit will also stipulate effluent limits and monitoring requirements.

(b) Hydrotest Discharge

Where will discharge take place? The hydrotest for the export pipeline is planned to take place during summer and will use only fresh water. Discharge may be to tundra in accordance with EPA general permit AKG-33-0000 (Authorization to Discharge Under the National Pollutant Discharge Elimination System (NPDES) for Facilities Related to Oil and Gas Extraction). This permit is currently expired but is expected to be reissued in 2010. If it not practicable to meet the effluent limits specified in the permit, then the water may be disposed of in the disposal well at Point Thomson Central Pad. If the disposal well is not available, an option would be to transport it by tanker trucks on barges during open water season to Prudhoe Bay for disposal at permitted facilities.

Where will the end of the pipe be? If the discharge is to tundra, the end of the pipe would be in the vicinity of the end of the pipeline at Point Thomson Central Pad.

At what depth? If discharged under EPA general permit AKG-33-0000, discharge would be to the surface.

What will the frequency of discharge be? Once per test, likely to be only one time. The dewatering activity following hydrotest is estimated to take one day or less.

What will be the volume of waste be? Estimated at 16,200 barrels.

What form of treatment will the waste stream go through? – The water would be filtered to remove solids, particulates, and other constituents in order to meet the NPDES discharge limitations.

(continued on back side)

Information Needed:	1. Which historical studies were used for determining site characteristics of soil, permafrost, geomorphology and other ground-related topics? 2. What depth to permafrost is being used and from which reference? There are two different depths cited in the ER (3.1.2.5, 3.1.2.1). 3. What soil texture % (sand, silt, clay, coarse fragments) by depth? What is depth of organic material? Is there eolian silt present at the surface? Where? How thick? 4. What is the ground ice content and form, i.e. ice volume percent, ice wedge volume, ice form (pore ice, reticulate, lenticular, etc.)? 5. Are there stratigraphy records or geotech borehole records? 6. For depth to permafrost, soil texture, ground ice, and stratigraphy, what is the spatial distribution? 7. For the soil pH to be taken in summer 2010, what methodology will be used? Will pH be taken at each soil horizon or at prescribed depths? Will pH be averaged across the depths or will a weighted average be used? 8. How will fines sieved from gravel be stored so as to prevent eolian erosion? 9. What design features will address/prevent thermo-erosion at culvert outlets? Will culverts be capped seasonally to prevent thermal regime changes? 10. What road fill depth will be used? 11. Fines from gravel extraction are proposed to be seasonally stored in ice pads (Project Description, 7.2.10). Will the material be removed before thaw? Where will the material be put? 12. Are there any road dust control measures in place? 13. In the ER (3.1.2.1), there was mention of longitudinal dunes, but no reference or further information. Is there a reference to go with this information?
Level of Detail:	Citations or copies of references and documentation

Comments and Rationale:

Aside from questions of soil pH which relate to corrosivity, each question above addresses topics related to preservation of the soil and permafrost thermal regime.

Response to Request for Information

RFI 46 – Geology, geomorphology, soils and permafrost

Date received 2/25/10

Date of Response: 3/24/10

To: Tim Gallagher HDR Project Manager, Scott Zitka

From: Peter Hanley, EIS SPOC, Jon Houghton Pentec

Response

1. Which historical studies were used for determining site characteristics of soil, permafrost, geomorphology and other ground-related topics?

Historical studies utilized for determining site characteristics; OCSEAP, HLA, and NORTEC from late 1970s through early 1980. Existing DMA work from mid -1990s to present including 1998, 2002, 2003, 2006, 2008, and 2009.

2. What depth to permafrost is being used and from which reference? There are two different depths cited in the ER (3.1.2.5, 3.1.2.1).

Depth to permafrost is identified in the ER as 1.5 to 2.0-feet in section 3.1.2.5 and 1 to 4-feet in section 3.1.2.1. Depth to permafrost was measured in late summer by DMA in 1998 and 2009. The most recent measurements (2009, DMA) show depth to permafrost at undisturbed tundra surfaces to range from 0.9- feet to 4.2-feet with an average of about 1.5-feet. The maximum extent of depth to permafrost was measured adjacent to bodies of water.

3. What soil texture % (sand, silt, clay, coarse fragments) by depth? What is depth of organic material? Is there eolian silt present at the surface? Where? How thick?

Golder is currently conducting a geotechnical exploration program for the Point Thomson project area. Based on data collected to date, a local on-shore general soil profile with maximum and minimum ranges is as follows;

- Peat and/or Organic Silt (surface organic layer) - Thickness ranges from 0.2 to 6.5-feet.
- Massive Ice; some with organic soil and/or gravel- Evident as random occurrence (not observed in all boreholes). Ranges in thickness from 0.8 to 22-feet. Exists below organic surface layer to depths of up to 23-feet. Some massive ice zones interbeded within sand and gravel layers at soil contact transition zones from organic surface layer to the underlying granular material.

- Sand and Gravel with zones of mineral silt/ clay- Sand and gravel layers include varying amount of fines content from clean sand and gravel to silty sand or silty gravel. Silt/clay interbeds range in thickness from 1-foot to 26.5-feet at depths up to 95-feet within the borehole depths drilled.

Silt below the organics is thought to be eolian. No mineral silt observed at the surface with the exception of very local rare occurrences (one occurrence observed within the current exploration program).

4. What is the ground ice content and form, i.e. ice volume percent, ice wedge volume, ice form (pore ice, reticulate, lenticular, etc.)?

Ground ice within soils varies widely. Large amount of wedge ice associated with polygonal ground (as described in the response to question #3). Also ice inclusions in the underlying gravel outwash deposits have been noted in historical studies and are evident in observations during the current exploration program.

5. Are there stratigraphy records or geotech borehole records?

Historical soil profile and borehole records exist from reports listed in #1 above and are being generated under the current exploration program.

6. For depth to permafrost, soil texture, ground ice, and stratigraphy, what is the spatial distribution?

Depth to permafrost and organic surface layer varies across the project sites as discussed in the response to question #2 and #3. The fines content and the silt/clay interbeds vary across the project site; however, with further analysis not yet completed, spatial variation may exist.

7. For the soil pH to be taken in summer 2010, what methodology will be used? Will pH be taken at each soil horizon or at prescribed depths? Will pH be averaged across the depths or will a weighted average be used?

pH will be performed on select samples within each soil horizon in the active layer and combined bulk samples from the material site soil which will be placed within the active layer zone during proposed construction of infrastructure.

8. How will fines sieved from gravel be stored so as to prevent eolian erosion?

Fines will not be sieved from the gravel. The material utilized for project purposes will be pit run.

9. What design features will address/prevent thermo-erosion at culvert outlets? Will culverts be capped seasonally to prevent thermal regime changes?

The majority of the culverts in the Point Thomson Project will be for seasonal cross drainage. As such, these culverts perform best with respect to water passage when placed near the tundra surface. Consistent with standard best practice, the underlying tundra mat performs best when left undisturbed.

Regarding protection of the tundra at culvert outlets, maintaining the existing tundra mat alleviates these issues in most instances; in other words, an undamaged, untouched tundra surface provides sufficient protection against erosion from intermittent flow. For larger streams with higher velocities, armoring, such as concrete revetment mats, may be required at the outlets, but these streams will be evaluated on an individual basis considering flow velocities and streambed particle size.

10. What road fill depth will be used?

5-feet minimum which is consistent with North Slope current design practice.

11. Fines from gravel extraction are proposed to be seasonally stored in ice pads (Project Description, 7.2.10). Will the material be removed before thaw? Where will the material be put?

Project Description 7.2.10 states that overburden will be temporarily placed on ice pads and then backfilled into the material site excavation pit before spring melt.

12. Are there any road dust control measures in place?

Water as required

13. In the ER (3.1.2.1), there was mention of longitudinal dunes, but no reference or further information. Is there a reference to go with this information?

This has been answered.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 55 – Barge Facility - Long term shoreline erosion protection

Question 1 - What is proposed for long term permanent shoreline erosion protection at the barge facility?

Question 2 - How will the shoreline and near shore water resources be protected? (We already heard the concern for maintaining fish passage during our scoping meetings.)

Date Received: 4/2/10

Date of Response: 6/9/10

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Response

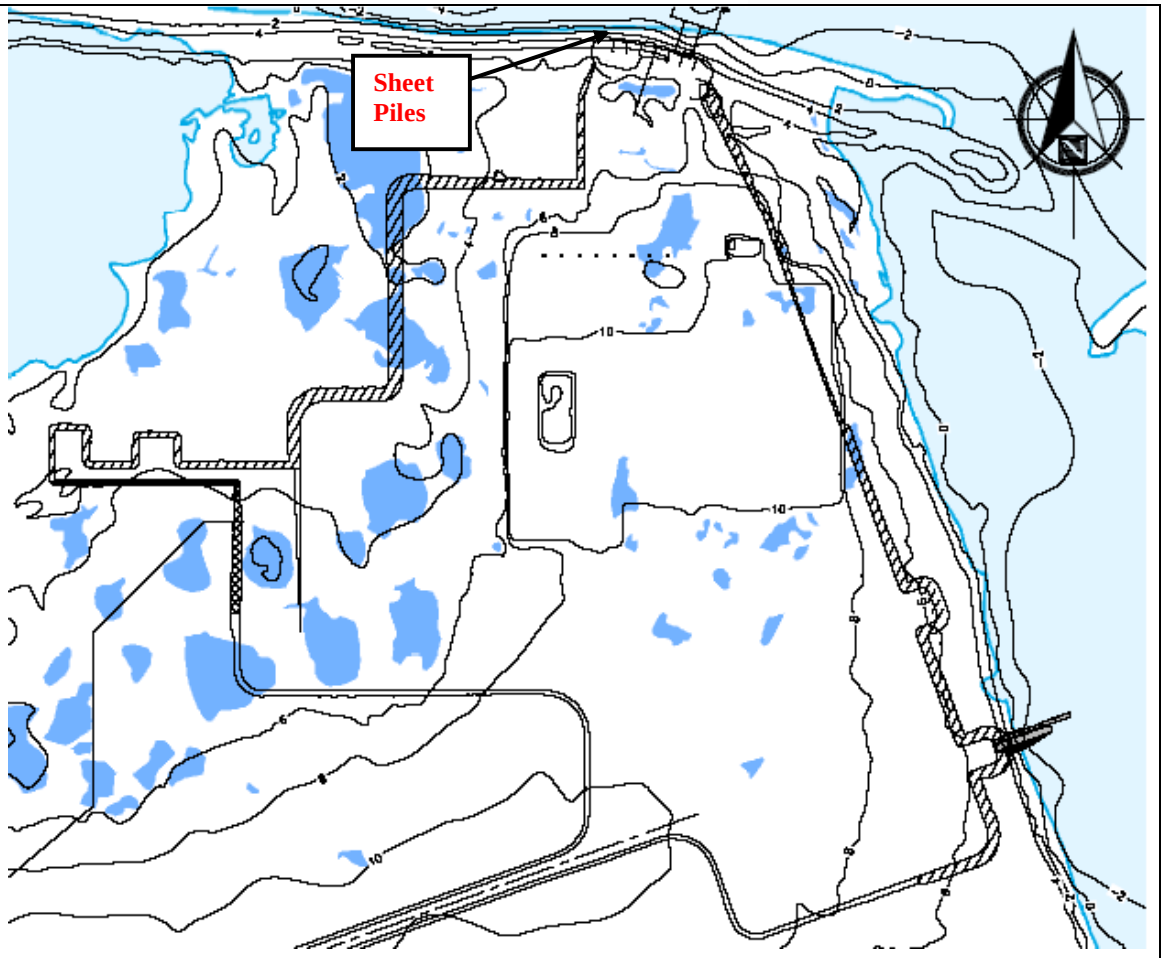
Question 1 - What is proposed for long term permanent shoreline erosion protection at the barge facility?

The barge facility consists of a 'high' bulkhead where ocean-going barges will offload sealift modules, and a 'low' bulkhead which will be used to offload materials and equipment from coastal barges. The seaward face of the proposed bulkheads is at elevation +1 ft, MLLW. The bulkheads are connected to the Central Pad via gravel ramps.

The shore protection being proposed for the bulkheads consists of a combination of sheet piles on the seaward face of the abutment and 4 cubic yard gravel bags on the East and West faces of the bulkhead. A detail of this shore protection is shown below.

(Continued on pg. 2)

.



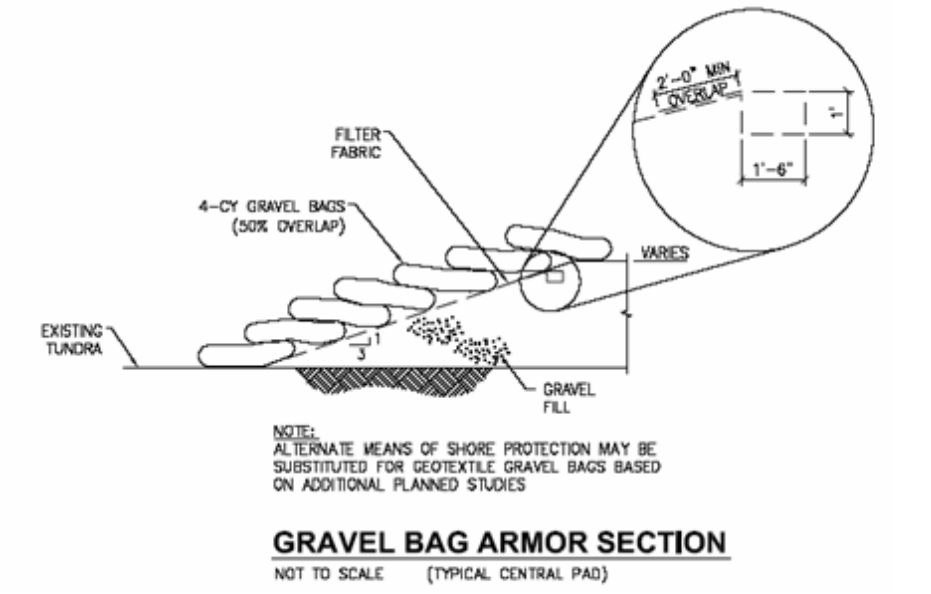


Fig 1a. Proposed Central Pad Shore Protection (see legend on next page for elevations of armor bags).

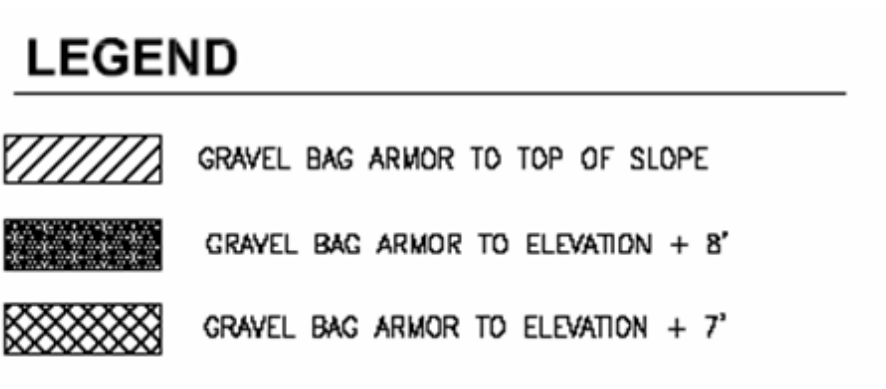

Figure 1 b. Detail of Proposed Central Pad Shore Protection

Rates of Erosion –
Erosion rates were calculated and changes in the shoreline shape analyzed. The calculated erosion rates are included in the below.

Table 1 - Point Thomson Project - Central Pad Summary

Gravel Pad	Pad elev. (feet, MLLW)	Run-up [1] (feet, MLLW)	Erosion Rate [2] 1955-2008 (feet/year)	Design Waves[3] (100 year return period)			
				Hs (feet)	Tp (seconds)	Direction (Azimuth)	Surge elev. (feet, MLLW)
Central	+13	+11	-1.2	9.6	12.6	355°	+6.0

1. Run-up elevations based on COBRAS wave model and considering eroded nearshore bathymetry
2. Maximum erosion rates based on shorter duration shoreline retreat trends indicate erosion to toe of gravel pads is possible.
3. Design waves are at a point offshore with seabed elevation at -10 feet, MLLW (water depth would be 16 feet with a +6 feet storm surge).

Answers to RFIs 17, 21, 23, and 26 also provide discussions of coastal erosion and the long term impacts of the water front facilities at Point Thomson.

Clarification of this RFI identified the need to provide a broader overview of the long term use of the bulkheads as well as the level of activity associated with other modes transportation providing logistical support during each phase of the project. The attached spreadsheet (Point Thomson Project Preliminary Summary of Logistics Plan) summarizes various modes of transportation and provides a description of the use/activity, details of the effects of the activity, and the duration and frequency of these activities during each phase of the project.

Question 2 - How will the shoreline and near shore water resources be protected? (We already heard the concern for maintaining fish passage during our scoping meetings.)

Given the stated concern for maintaining fish passage, this response interprets "near shore water resources" to mean "nearshore biota". Shoreline sediments all along the North Slope coast are active with littoral drift and are seasonally disturbed by bottom-fast ice, so there is typically minimal sedentary biological life that exists in near shore sediments. The most important biota in the area are motile epibenthic invertebrates and fish. During offloading operations a small amount of dredging (<1500 cu yd) will occur at 70+ feet offshore from the facility (this dredging will occur during the previous winter and only summer screeding may occur, if needed). The short-term grounding of the barges during mid summer should have minimal to no effect on these nearshore biota.

Observations of the shoreline morphology throughout the Point Thomson area, indicate that sediment transport in both the east and west directions occur. It cannot be determined with certainty how much sediment transport is occurring each year, or which direction will predominate in the future. A goal of the 2010 bathymetryic survey will be to re-survey old scours to determine the previous year's sediment in-filling rate. This data, along with historical beach profile information, will allow the Project to better understand the processes the shoreline development. Longshore transport estimates have important implications for the design of any structure that could potentially block the longshore transport of beach sediment. However, the proposed module offload facility does not extend completely across the beach. The face of the bulkhead is at elevation +1 feet, MLLW. Therefore, the module offload facility is limited in the quantity of longshore sediment movement that could potentially be retained by the structure. The proposed bulkhead is small enough, relative to the width and depth of the existing beach and ongoing shoreline changes, that any affect on shoreline processes will be minimal.

Effects on erosion caused by the grounded sealift barges are also expected to be minimal and temporary. As described in Section 4.1.4 of the Environmental Report, when the sealift barges are in place, the littoral transport would be interrupted, causing sediment deposition on the upwind side and erosion on the downwind side of the array. Since the barges would only be in place for about two weeks during each of up to three construction years, it is unlikely that any effects on shoreline processes would be significant.

Also, when the barge bridge is in place for the offload of sealift modules, there will be open water spaces between the linked, grounded barges created by the angle of the bows and sterns. This is illustrated in the attached Figures which show typical barge links.

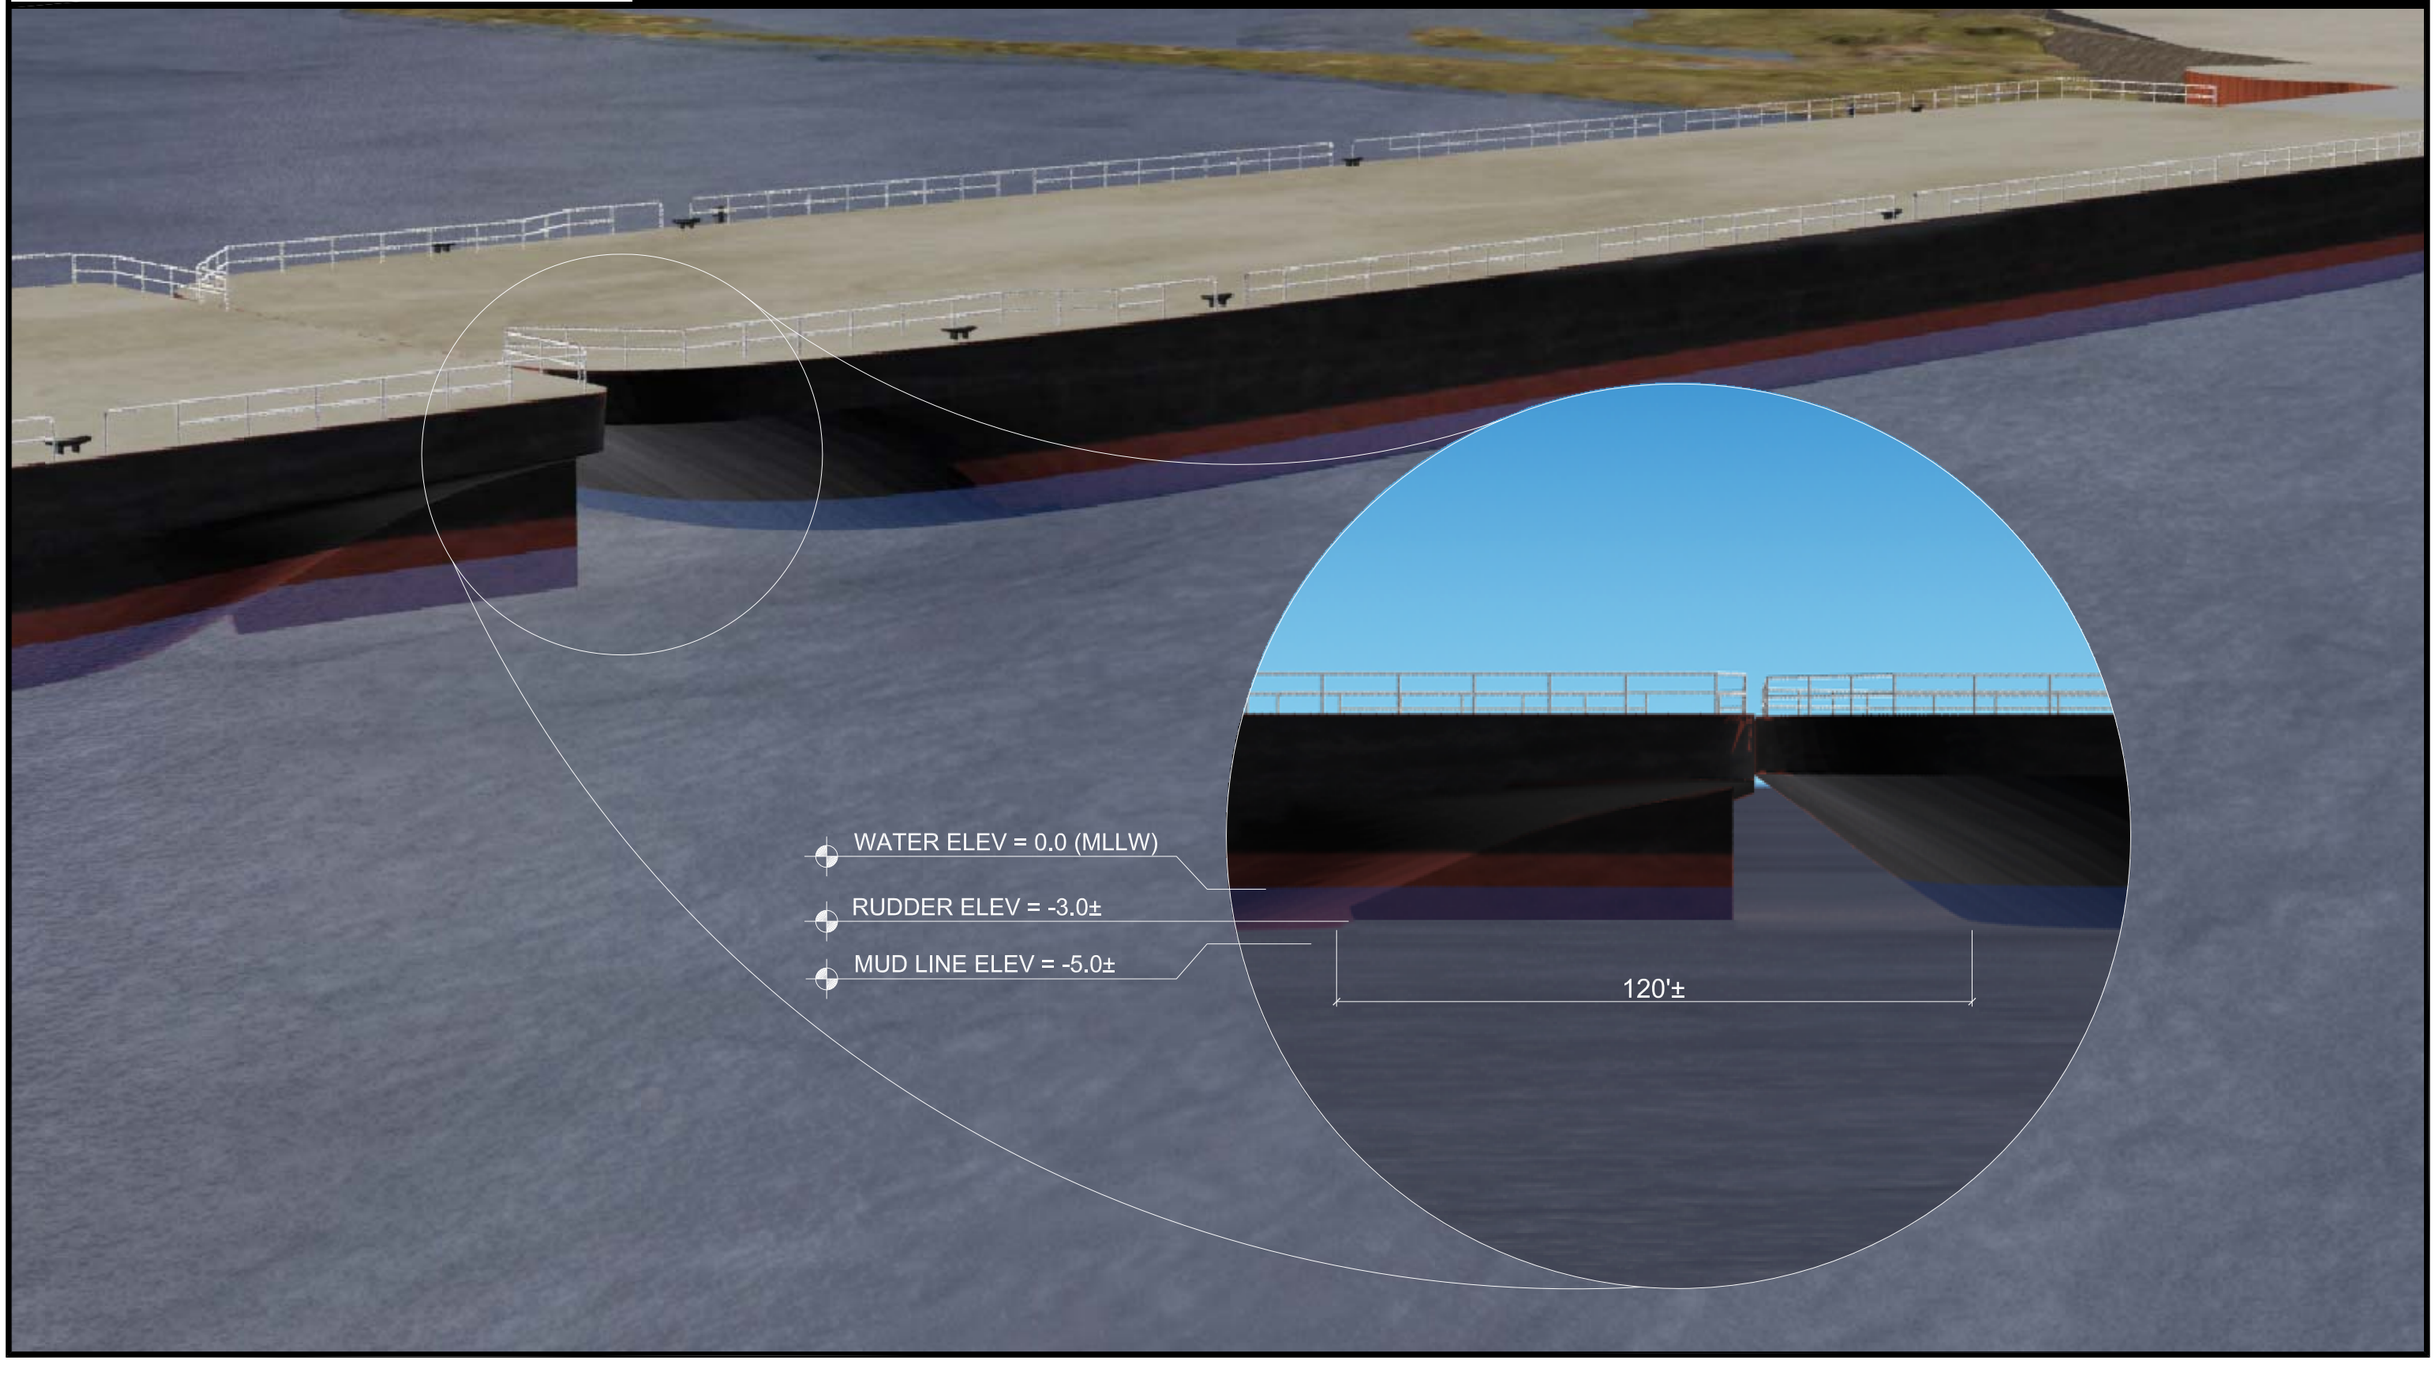
POINT THOMSON PROJECT - PRELIMINARY SUMMARY OF LOGISTICS PLAN

Construction					
Project Phase	**Purpose**	**Description of Operation**	**Shoreline**	**Number, Frequency, and Season**	**Duration per Trip and Duration of Offload**
Sealift Barging	Transport facility modules	Offloads modules at high bulkhead. Ballasting and de-ballasting (1,700 gpm). Mooring Dolphins to secure barges. A transit tug of ocean going type will be used to bring the sealift barges to offshore Point Thomson in deeper water then the final approach by shallow draft tugs. Generally the sealift barges will require two or three assist tugs during "docking" operations and offloading. These are shallow draft river tugs (draft requirements of 3 to 4 feet). No deck washing will take place during the beaching, docking or offloading at the Point Thomson site. No barge cleaning will be done in coastal waters. All will be done under the control of the barge owners in their facilities and in controlled conditions.	Minor contour dredging in winter before first barging season. Minor maintenance screeding prior to each year's sealift operation. The contour dredging is performed in winter months by removing the ice, dredging material using a backhoe, and then placing the dredged material on the beach above MHW. Ballasting operations are performed using deck mounted pumps and associated hoses. The ballast water is taken from the surface waters to avoid any silts or bottom materials from being withdrawn. Ballast water will be discharged to the same general area.	7 to 9 barges for up to three construction seasons during summer barging season.	Total time will depend upon point of origin, which has not yet been determined. In the Beaufort Sea, the estimated time is 2 days from Barrow to Pt Thomson, 2 weeks offload operation at Point Thomson (off loading all 7-9 barges). 2 to 3 days to exit Beaufort Sea via Point Barrow.
Coastal Barging – Central Pad	Re-supply of fuel, materials, equipment, and piping. Removal of waste, surplus equipment, etc.	Offloads at low bulkhead via barge ramp. No ballasting / de-ballasting. One tug assist required for bringing the barge to the bulkhead and holding while off loading. Tugs and barges are river class vessels that have draft requirements of 3 to 4 feet or water. No deck washing will be performed at Point Thomson or other coastal water. These operations will be conducted under the provisions of a Conflict Avoidance Agreement (CAA) with the Alaska Eskimo Whaling Commission. General barging activity will employ active sea mammal avoidance measures for all operations.	No maintenance dredging required.	2 to 4 barges every year during summer barging season. There will be as many as 40 to 50 round trips per barge during the nominal July 15 to August 25 barging season. Note there are tradeoffs between the level of coastal barging activity and the use of an ice road.	The coastal barges take approximately 10-12 hours to transit from Prudhoe Bay to Point Thomson. Offloading takes approximately 4 to 6 hours depending on the type of cargo and load.
Coastal Barging – Other Pads	Delivery of certain materials, equipment, camps and construction equipment may be made to East Pad and the Badami Dock. These would be performed on a "as required" basis for the support of work at these locations. The most frequent location of delivery, other than the Point Thomson Central Pad site, would be the Badami site. The Badami site has an existing improved barge off-loading causeway that facilitates off-loading and movement of materials and equipment to this site.	The typical 200 ft long x 60 ft wide coastal shallow draft barges would be loaded at the West Dock of Prudhoe bay and transited to the East Pad location via shallow draft tugs. Off-loading would be accomplished by pushing the barges as close into the shoreline as possible. The materials and equipment would then be driven off the barge across a typical ramp to the beach and onto the existing pads at these locations. At Badami, materials would be offloaded over the existing dock.	Approaches for the East Pad off-loads would avoid any tundra or unprotected areas. Wooden rigging mats may be temporarily laid on the beach and approach to the pad to even the route and avoid any soft or uneven areas. The Badami dock is a gravel structure.	These deliveries would be irregular in frequency and will be accomplished during the usual Mid-July to end August summer barging season.	The barges would be on the beach for off-loading or reloading for only a limited number of hours for each shipment. The normal time to off-load the barges and reload with any leaving equipment is usually less than six hours. No excavations, dredging or piles need be used for the normal delivery operations at these sites with the barges intended for use. These small coastal barges are not ballasted for operations.

Construction					
Project Phase	**Purpose**	**Description of Operation**	**Shoreline**	**Number, Frequency, and Season**	**Duration per Trip and Duration of Offload**
C-130 Airlifts	Transport or re-supply of critical materials or equipment. C-130 type aircraft will not be used on a regular basis. They will only be used when materials or equipment cannot be moved via other means in a timely manner.	Land at airstrip. Loads will be trucked from airstrip to Central Pad on the gravel connecting roads.	N/A	Only 1 to 2 flights are expected through 2013. One flight carries the equivalent of 1/16 of a barge load or roughly equivalent to ½ of a tractor / trailer load.	Normal flight time is I hour from Deadhorse or 2 and 1/2 hours from Anchorage. One day to offload and take off.
Fixed Wing Cargo and Passenger Aircraft	Transport normal operational materials, equipment, supplies, groceries, etc. These aircraft will also transport personnel from Deadhorse and Point Thomson.	Land at the gravel airstrip. Loads will be trucked or bussed from the airstrip to the Central Pad on the connecting roads.	The typical aircraft will be Beechcraft 1900, Cassas or Twin Otter size turbo prop aircraft. Normal payloads are approximately 5000 lbs max, and can transport 12-19 passengers.	After completion and certification of the gravel airstrip in 2012, flights would be 2 to 3 per day depending on the manpower needs or resupply requirements. Fixed wing air flights will transit 5 miles south of the coastline when east of Bullen Point and then approach the airstrip from a southerly direction (contingent upon weather and other safety considerations) and be adjusted to avoid any wildlife concentrations.	1 hour from Deadhorse. 1-2 hours to offload and take off.
Helicopter	Transport normal operational materials, equipment, supplies, groceries, etc. These aircraft will also transport personnel from Deadhorse to the Point. Thomson sites.	Land at the Central pad and other designated landing areas. Landings will occur at the gravel airstrip, when available. Loads will be trucked or bussed from the helipads Airstrip to the Central Pad on the connecting roads.	The intended aircraft will be 12 to 15 passenger helicopters. These will be wheeled or ski equipped for landing on a helipad or on gravel. Normal payloads for cargo are approximately 1200 to 3000 lbs.	Flights would be 2 to 3 per day depending on the manpower or resupply requirements Helicopter flights will transit 5 miles south of the coastline when east of Bullen Point and then approach the airstrip from a southerly direction (contingent upon weather and other safety considerations)	The normal transit time from Deadhorse to Point Thomson is 1hours per round trip and 1-2 hours to offload and takeoff
Ice Road (trucks and other)	Transport normal construction materials, equipment, supplies, groceries, etc. The ice road may be used to transport personnel via crew bus between Deadhorse and the Point Thomson work sites.	Ice roads will be built during the December through January winter time frame or as temperatures allow as has been done for the drilling program. The intended ice road will be along the natural coast line from the Prudhoe Bay area to Point Thomson. Security will control access and monitor vehicle traffic. All trucks and vehicles are checked for leaks and mechanical issues. "Duck Ponds" are required for all stops and engine idle times. ExxonMobil's Polar Bear and Wildlife Interaction Plan will be followed to minimize potential impacts to polar bears and other wildlife in the area, This will include FLIR surveys. Visual monitoring for wildlife presence to facilitate avoidance will be required.	Ice roads will be built close to the natural coast line to insure a grounded ice base. Seawater will be used to establish base and thickness and fresh water and ice chips will be used to firm the surface.	The ice road will be transited continuously from completion until closing, approximately February 1 to May 1 time frame with as many as 20 trucks per day during the peak of construction. Note there are tradeoffs between the use of an ice road and the level of coastal barging activity.	The normal transit time from Deadhorse to Point Thomson is 2- 3 hours for normal trucks or buses.
Ice Airstrip	Ice airstrips are not currently planned to be used.				

Drilling					
Project Phase	**Purpose**	**Description of Operation**	**Shoreline**	**Number, Frequency, and Season**	**Duration per Trip and Duration of Offload**
Sealift Barging	Not proposed	N/A	N/A	N/A	N/A
Coastal Barging – Central Pad	Re-supply of fuel, materials, equipment.	Same as described for construction.		The number and frequency will be dictated by the needs of the drilling operations. About 100 barge loads per drilling season can be expected.	Same as described for construction
Coastal Barging – Other Pads	Possible delivery of certain equipment may be made to the East Pad.	Same as described for construction	Same as described for construction	Same as described for construction	Same as described for construction
C-130 Airlifts	Same as described for construction	Land at Airstrip. Loads must be trucked from Airstrip to the well pads on the gravel connecting roads.	Same as described for construction	C-130 flights will be used to respond to emergency situations or need to repair or replace essential equipment.	Same as described for construction
Cargo and passenger Aircraft	Same as described for construction	Same as described for construction	Same as described for construction	Same as described for construction; anticipate 2 – 3 flights per day to support drilling operations	Same as described for construction
Helicopter aviation	Transport normal operational materials, equipment, supplies, and groceries. These aircraft will also transport personnel from Deadhorse to the Point Thomson Site. These flights will be coordinated with construction or operations needs.	Same as described for construction	Same as described for construction	Flights would be 2 to 3 per day depending on the drilling manpower needs or resupply requirements. Other aspects are the same as described for construction.	Same as described for construction
Ice Road (trucks and other)	Ice road use for drilling will be coordinated with the requirements of construction and operations, depending upon timing. Coordinated use of the same resources will be managed to minimize traffic and additional vehicles. Transport normal operational materials, equipment, supplies, groceries, etc. The ice road may be used to transport personnel via crew bus to and from Deadhorse, Point Thomson and other work sites.	Same as described for construction	Ice roads will be built close to the coast line to insure a grounded ice base. Seawater will be used to establish base and thickness and fresh water and ice chips will be used to firm the surface.	Same as described for construction	Same as described for construction
Ice Airstrip	Ice airstrips are not currently planned to be used.				



Operations					
Project Phase	**Purpose**	**Description of Operation**	**Shoreline**	**Number, Frequency, and Season**	**Duration per Trip and Duration of Offload**
Sealift Barging	Not proposed.	N/A	N/A	N/A	N/A
Coastal Barging – Central Pad	Re-supply of fuel, materials, equipment, piping, and removal of waste, surplus, return equipment, etc.	Same as described for construction	Same as described for construction	2 barges every year during summer barging season. There will be as many as 20 to 30 round trips per barge during the July 15 to August 25 normal barging season.	Same as described for construction
Coastal Barging – Other Pads	Possible delivery of certain materials and equipment may be made to East Pad.	Same as described for construction	Same as described for construction	Not scheduled or anticipated but possible (for example to move oversized equipment).	Same as described for construction
C-130 airlifts	Same as described for construction	Same as described for construction	N/A	It is not possible to predict the frequency for operations for this non-routine activity	Same as described for construction
Fixed Wing Cargo and passenger Aircraft	Same as described for construction	Same as described for construction	Same as described for construction	Same as described for construction	Same as described for construction
Helicopter aviation	Helicopters will be used only when fixed wing flights are not practical for the intended purpose or for special purposes. There will be minimal helicopter usage. Transport normal operational materials, equipment, supplies, groceries, etc. These aircraft may also transport personnel from Deadhorse to the Point Thomson Site. Helicopters may also be used for pipeline surveillance and field studies.	Land at the gravel airstrip. Load to trucks or buses from the airstrip to the Central Pad on the connecting roads.	The intended aircraft will be 12 to 15 passenger helicopters. These will be wheeled or ski equipped for landing on a helipad or on the tundra. Normal payloads for cargo are approximately 1200 to 3000 lbs max, and can transport 12 - 15 passengers.	Flights would be as needed for specific purposes.	The normal transit time from Deadhorse to Point Thomson is 1- 2 round trip hours for normal passenger or cargo.
Ice Road (trucks and other)	It is not planned to construct and use ice roads during ongoing operations. There may be some years, however, in which ice roads are required, such as to mobilize or demobilize drilling or workover rigs or transporting large quantities of heavy materials.	Any ice roads required for operations will be built and operated in a similar manner to that described under construction. Ice roads for operations, however, will be built and used for special purposes, which may allow a “lighter duty” ice road or for a shorter duration.	Same as for construction.	Not intended to be a primary or annual mode of transportation. Barge will be primary mode for annual re-supply.	Same as described for construction
Ice Airstrip	Not planned for use during operations

(continued on back side)

Information Needed:	Emissions associated with drilling, construction, and operational activity
Level of Detail:	Emissions due to project-related processes, both during construction and operation: 1. NO_x 2. CO 3. PM_{10} 4. $PM_{2.5}$ 5. VOC 1. SO_2

Comments and Rationale:

Level of Priority: ☐ Low ☒ Standard ☐ High ☐ Extreme

Time Sensitivity: ☐ Low ☒ Standard ☐ High

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 57 – Potential Emissions

Total potential emissions associated with operations and drilling/construction activities at Point Thomson.

Date Received: 4/2/10

Date of Response: 4/26/10

To: Tim Gallagher HDR Project Manager, Jeanette Brena

From: Peter Hanley, EIS SPOC

Response

Point Thomson project air emissions are emitted by stationary emission units and non-road engines associated with the operations and drilling/construction phases of the project. Summaries of the potential total emissions from the Point Thomson during operations and drilling/construction phases of the project are listed below.

Total Potential Emissions from Point Thomson – Operations[1]

Pollutant	Stationary Emission Units Potential Emissions	Non-road Engines Potential Emissions[2]	Total Potential Emissions
NO_X	234.7 tpy	953.8 tpy	1,188.5 tpy
CO	188.8 tpy	206.5 tpy	395.3 tpy
PM_{10}	21.7 tpy	14.4 tpy	36.1 tpy
$PM_{2.5}$	20.5 tpy	14.4 tpy	34.9 tpy
VOC	63.1 tpy	95.9 tpy	159.0 tpy
SO_2	9.9 tpy	0.6 tpy	10.6 tpy

[1]Information subject to change as design progresses.
[2]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway.

The operations emission unit inventory used for calculating the total potential emissions is based on a preliminary emission unit inventory that has not yet been finalized. The preliminary emission unit inventory consists of new emission units that

will be installed as part of the production facility and existing emission units associated with drilling operations.

Total Potential Emissions from Point Thomson – Drilling/Construction[1]

Pollutant	Stationary Emission Units Potential Emissions	Non-road Engines Potential Emissions[2]	Total Potential Emissions
NO_X	232.3 tpy	978.2 tpy	1,210.5 tpy
CO	203.8 tpy	196.9 tpy	400.7 tpy
PM_{10}	18.7 tpy	14.3 tpy	33.0 tpy
$PM_{2.5}$	17.1 tpy	14.3 tpy	31.4 tpy
VOC	40.0 tpy	98.3 tpy	138.3 tpy
SO_2	18.9 tpy	0.7 tpy	19.6 tpy

[1]Information subject to change as design progresses.
[2]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway

The drilling/construction emission unit inventory used for calculating the total potential emissions is the emission unit inventory from the air quality minor permit application submitted to Alaska Department of Conservation (ADEC) on November 4, 2009.

All emission unit inventories are subject to change as detail design work proceeds.

Total Potential Emissions Methodology

The total potential emissions for were calculated using vendor data, Environmental Protection Agency (EPA) AP-42 emission factors, mass balances, and New Source Performance Standards (NSPS) for reciprocating internal combustion engines. The total potential emissions were calculated assuming that each emission unit operates continuously (8,760 hours per year) at maximum load except for those emissions units that will be subject to operating restrictions under the ADEC-issued air quality permit. The potential emissions for restricted emission units were calculated assuming those emission units were operated at the maximum permitted load for the maximum allowed hours per year.

The detailed total potential emission calculations for Point Thomson operations are provided in Tables 1 through 11. The detailed total potential emission calculations for Point Thomson drilling/construction are provided in Tables 12 through 19.
