Table 13. Point Thomson Drilling/Construction - Emission Unit Inventory

Emission Unit No.	Identification	Description	Maximum Fuel Consumption	Maximum Capacity	Maximum Operation
1	Industrial Combustion KLG-42	Drill Rig Boiler #1	30 gal/hr	4.200 MMBtu/hr	8,760 hr/yr
2	Industrial Combustion ML-63P	Drill Rig Boiler #2	45 gal/hr	6.300 MMBtu/hr	8,760 hr/yr
3	Iron Fireman C-240-F-4.2	Drill Rig Pipeshed Tioga Air Heater #1	30 gal/hr	4.200 MMBtu/hr	8,760 hr/yr
4	Iron Fireman C-240-F-4.2	Drill Rig Pipeshed Tioga Air Heater #2	30 gal/hr	4.200 MMBtu/hr	8,760 hr/yr
5	Industrial Combustion ML-63P	Drill Rig Support Boiler #1	45 gal/hr	6.300 MMBtu/hr	8,760 hr/yr
6	Industrial Combustion ML-63P	Drill Rig Support Boiler #2	45 gal/hr	6.300 MMBtu/hr	8,760 hr/yr
7	Reznor OH190	Drill Rig Support Shop Unit Air Heater #1	1.65 gal/hr	0.229 MMBtu/hr	8,760 hr/yr
8	Reznor OH190	Drill Rig Support Shop Unit Air Heater #2	1.65 gal/hr	0.229 MMBtu/hr	8,760 hr/yr
9	Cummins QSX15-G9	Alaska Camp Generator Engine #1	34.7 gal/hr	732 hp	8,760 hr/yr
10	Cummins QSX15-G9	Alaska Camp Generator Engine #2	34.7 gal/hr	732 hp	8,760 hr/yr
11	Consumat C32P	Alaska Camp Waste Incinerator	3 gal/hr	130 lb/hr	8,760 hr/yr
12	John Deere 6090HF485V	Warehouse Generator Engine #1	21.56 gal/hr	422 hp	8,760 hr/yr
13	John Deere 6090HF485V	Warehouse Generator Engine #2	21.56 gal/hr	422 hp	8,760 hr/yr
14	Tioga IDF-11DO	Warehouse Heater #1	18.4 gal/hr	2.386 MMBtu/hr	8,760 hr/yr
15	Tioga IDF-11DO	Warehouse Heater #2	18.4 gal/hr	2.386 MMBtu/hr	8,760 hr/yr
16	Weil-McLain 1688	Bulk Tank Storage Area Boiler #1	35.5 gal/hr	4.97 MMBtu/hr	8,760 hr/yr
17	Weil-McLain 1788	Bulk Tank Storage Area Boiler #2	38 gal/hr	5.32 MMBtu/hr	8,760 hr/yr
18	Perkins 2306C-E14 TAG	Bulk Tank Storage Area Generator Engine #1	25.69 gal/hr	375 kW	8,760 hr/yr
19	Perkins 2306C-E14 TAG	Bulk Tank Storage Area Generator Engine #2	25.69 gal/hr	375 kW	8,760 hr/yr
20	MMD Power Pro 150	Bulk Tank Storage Area Generator Engine #3	8.7 gal/hr	190 hp	8,760 hr/yr
21	MMD Power Pro 150	Bulk Tank Storage Area Generator Engine #4	8.7 gal/hr	190 hp	8,760 hr/yr
22	Therm Dynamics Caterpillar C6.6	Bulk Tank Storage Area Heater Engine #1	8.6 gal/hr	165 hp	8,760 hr/yr
23	Therm Dynamics Caterpillar C6.6	Bulk Tank Storage Area Heater Engine #2	8.6 gal/hr	165 hp	8,760 hr/yr
24	Magnum 80 John Deere 4045TF275D	Water Tank Farm Generator Engine	5.6 gal/hr	84 kW	8,760 hr/yr
25	ES 700	Portable Heater #1	5.1 gal/hr	0.7 MMBtu/hr	8,760 hr/yr
26	ES 700	Portable Heater #2	5.1 gal/hr	0.7 MMBtu/hr	8,760 hr/yr
27	ES 700	Portable Heater #3	5.1 gal/hr	0.7 MMBtu/hr	8,760 hr/yr
28	Whisperwatt Isuzu AA4LE2	Heliport Engine	1.44 gal/hr	35.9 hp	8,760 hr/yr
29	Magnum 55 John Deere PE5030TF270	Annex Camp Generator	4.0 gal/hr	60 kW	8,760 hr/yr
30	Miscellaneous Boiler and Heater	Portable Heater #1	20.1 gal/hr	2.75 MMBtu/hr	8,760 hr/yr
31	Miscellaneous Boiler and Heater	Portable Heater #2	20.1 gal/hr	2.75 MMBtu/hr	8,760 hr/yr
32	Miscellaneous Boiler and Heater	Portable Heater #3	20.1 gal/hr	2.75 MMBtu/hr	8,760 hr/yr
33	Miscellaneous Boiler and Heater	Portable Heater #4	20.1 gal/hr	2.75 MMBtu/hr	8,760 hr/yr
34	Miscellaneous Boiler and Heater	Portable Heater #5	20.1 gal/hr	2.75 MMBtu/hr	8,760 hr/yr

			Total Potential NO_X Emissions Excluding Non-Road Engines			232.3 tpy
			Total Potential NO_X Emissions for All Emission Units			1,210.5 tpy

Notes:
1. NOx vendor data for EU IDs 20 - 23, 28, and 40 - 45 is NMHC + NOx.
2. Calculations used emission rate and load that resulted in the worst-case tpy.
3. EU IDs 38 - 64 are nonroad engines.

				Total Potential CO Emissions Excluding Non-Road Engines		203.8 tpy
				Total Potential CO Emissions for All Emission Units		400.7 tpy

Notes:
1. CO vendor data for EU IDs 24, 29, 63 and 64 are the parent ratings.
2. Calculations used emission rate and load that resulted in the worst-case tpy.
3. EU IDs 38 - 64 are nonroad engines.

			Total Potential PM_{10} Emissions Excluding Non-Road Engines			18.7 tpy
			Total Potential PM_{10} Emissions for All Emission Units			33.0 tpy

Notes:
1. Calculations used emission rate and load that resulted in the worst-case tpy.
2. For the flare, used a lightly smoking emission factor for PM-10 of 40 ug/L, converted as follows:
   (40 ug / L exhaust)(lb / 453.6 * 10^6 ug)(28.32 L exhaust / scf exhaust)(10.6 scf exhaust / scf gas)(10^6 scf / MMscf) = 26.47 lb/MMscf
3. EU IDs 38 - 64 are nonroad engines.

			Total Potential $PM_{2.5}$ Emissions Excluding Non-Road Engines			17.1 tpy
			Total Potential $PM_{2.5}$ Emissions for All Emission Units			31.4 tpy

Notes:
1. Calculations used emission rate and load that resulted in the worst-case tpy.
2. For the flare, used a lightly smoking emission factor for PM-10 of 40 ug/L, converted as follows:
   (40 ug / L exhaust)(lb / 453.6 * 10^6 ug)(28.32 L exhaust / scf exhaust)(10.6 scf exhaust / scf gas)(10^6 scf / MMscf) = 26.47 lb/MMscf
3. EU IDs 38 - 64 are nonroad engines.

			Total Potential SO_2 Emissions Excluding Non-Road Engines			18.9 tpy
			Total Potential SO_2 Emissions for All Emission Units			19.6 tpy

Notes:
1. Diesel fuel is assumed to have a sulfur content of 15 ppm sulfur and a heat content of 137,000 Btu/gal (19,300 Btu/lb fuel) and a density of 7.1 lb/gal.
2. For natural gas units (flare), calculations used a H2S content of 250 ppm and conversions of 1020 Btu/scf.
3. Calculations used emission rate and load that resulted in the worst-case tpy.
4. EU IDs 38 - 64 are nonroad engines.

Table 1. Point Thomson - Production Facility Operations

Pollutant	Stationary Emission Units Potential Emissions	Non-road Engines Potential Emissions	Total Potential Emissions
NO_X	234.7 tpy	953.8 tpy	1,188.5 tpy
CO	188.8 tpy	206.5 tpy	395.3 tpy

			Total Potential VOC Emissions Excluding Non-road Engines			63.1 tpy
			Total Potential VOC Emissions for All Emission Units			159.0 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. Inlet air heating on combustion turbines.
3. Higher potential VOC emissions result from dual fired turbines firing 8,760 hr/yr on fuel gas, than firing 1,000 hr/yr on ULSD and 7,760 hr/yr on fuel gas.

Notes:
1. Diesel fuel is assumed to have a sulfur content of 15 ppmw (0.15 wt. pct.) and a heat content of 137,000 Btu/gal.
2. Diesel engine heat rate assumed to be 7,000 Btu/hp-hr.
3. Fuel gas has a heat content of 1,020 Btu/scf and H_2S of 25 ppmv.
4. The Solar Taurus 70 turbine has a heat rate of 10,100 Btu/kW-hr.

Notes:
1. Based on valid data collected from January 1, 2001 through December 31, 2006.
2. Assumes the inlet air to the turbines is heated to 0 degrees F.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 57 – Potential Emissions

Total potential emissions associated with operations and drilling/construction activities at Point Thomson.

Date Received: 4/2/10

Date of Response: 4/15/10

Date of Revision: 8/10/10

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Response

Point Thomson project air emissions are emitted by stationary emission units and non-road engines associated with the operations and construction phases of the project. Summaries of the potential total emissions from the Point Thomson during operations and construction phases of the project are listed below.

Total Potential Emissions from Point Thomson – Operations[1]

Pollutant	Stationary Emission Units Potential Emissions	Non-road Engines Potential Emissions[2]	Total Potential Emissions
NO_X	912.9 tpy	989.2 tpy	1,902.1 tpy
CO	1,128.2 tpy	222.9 tpy	1,351.2 tpy
PM_{10}	44.0 tpy	16.8 tpy	60.8 tpy
$PM_{2.5}$	44.0 tpy	16.8 tpy	60.8 tpy
VOC	183.7 tpy	101.0 tpy	284.7 tpy
SO_2	8.8 tpy	0.7 tpy	9.5 tpy

[1]Information subject to change as design progresses.
[2]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway.

The operations emission unit inventory used for calculating the total potential emissions is based on a preliminary emission unit inventory that has not yet been finalized. The

preliminary emission unit inventory consists of new emission units that will be installed as part of the production facility and existing emission units associated with drilling operations.

Total Potential Emissions from Point Thomson – Construction[1]

Pollutant	Stationary Emission Units Potential Emissions	Non-road Engines Potential Emissions[2]	Total Potential Emissions
NO_X	254.5 tpy	953.8 tpy	1,208.3 tpy
CO	237.9 tpy	206.5 tpy	444.4 tpy
PM_{10}	23.4 tpy	14.4 tpy	37.7 tpy
$PM_{2.5}$	23.4 tpy	14.4 tpy	37.7 tpy
VOC	72.0 tpy	95.9 tpy	168.0 tpy
SO_2	16.7 tpy	0.6 tpy	17.3 tpy

[1]Information subject to change as design progresses.
[2]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway

The drilling emission unit inventory used for calculating the total potential emissions is the emission unit inventory from the air quality minor permit application submitted to Alaska Department of Conservation (ADEC) on November 4, 2009.

All emission unit inventories are subject to change as detail design work proceeds.

Total Potential Emissions Methodology

The total potential emissions for were calculated using vendor data, Environmental Protection Agency (EPA) AP-42 emission factors, mass balances, and New Source Performance Standards (NSPS) for reciprocating internal combustion engines. The total potential emissions were calculated assuming that each emission unit operates continuously (8,760 hours per year) at maximum load except for those emissions units that will be subject to operating restrictions under the ADEC-issued air quality permit. The potential emissions for restricted emission units were calculated assuming those emission units were operated at the maximum permitted load for the maximum allowed hours per year.

The detailed total potential emission calculations for Point Thomson operations and construction are provided in Tables 1 through 7.

Notes: 1. Emission units associated with the current drilling operation are listed as Emission Units 1 through 64.
2. ULSD = Ultra Low Sulfur Diesel
3. Calculations used conversions of 19,300 Btu/lb liquid fuel, 7.1 lb liquid fuel/gal, and 7,000 Btu/hp-hr.
4. Dual fired turbines are restricted to 1,000 hr/yr while firing on ULSD, and unrestricted operation while firing on fuel gas.

Table 3. Point Thomson Production Facility - Potential NO_X Emissions

Emission Unit No.	Emission Unit Identification	NO_X Emission Factor Reference	NO_X Emission Factor	Maximum Capacity	Maximum Operation During Construction	Maximum Operation During Operations	Potential NO_X Emissions During Construction	Potential NO_X Emissions During Operations

					Total Potential CO Emissions Excluding Non-road Engines		1128.2 tpy	237.9 tpy
					Total Potential CO Emissions for All Emission Units		1351.2 tpy	444.4 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. Inlet air heating on combustion turbines.
3. Camp engine (Emission Units 9 and 10) potential emission based on 90 percent load as worst-case potential emissions.

Table 5. Point Thomson Production Facility - Potential PM_{10} Emissions

Emission Unit No.	Emission Unit Identification	PM_{10} Emission Factor Reference	PM_{10} Emission Factor	Maximum Capacity	Maximum Operation During Construction	Maximum Operation During Operations	Potential PM_{10} Emissions During Construction	Potential PM_{10} Emissions During Operations

			Total Potential VOC Emissions Excluding Non-road Engines				183.7 tpy	72.0 tpy
			Total Potential VOC Emissions for All Emission Units				284.7 tpy	168.0 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. Inlet air heating on combustion turbines.
3. Higher potential VOC emissions result from dual fired turbines firing 8,760 hr/yr on fuel gas, than firing 1,000 hr/yr on ULSD and 7,760 hr/yr on fuel gas.

Table 7. Point Thomson Production Facility - Potential SO_2 Emissions

Emission Unit No.	Emission Unit Identification	SO_2 Emission Factor Reference	SO_2 Emission Factor	Maximum Capacity	Maximum Operation During Construction	Maximum Operation During Operations	Potential SO_2 Emissions During Construction	Potential SO_2 Emissions During Operations

			Total Potential SO_2 Emissions Excluding Non-road Engines				8.8 tpy	16.7 tpy
			Total Potential SO_2 Emissions for All Emission Units				9.5 tpy	17.3 tpy

Notes:
1. Diesel fuel is assumed to have a sulfur content of 15 ppmw (0.15 wt. pct.) and a heat content of 137,000 Btu/gal.
2. Diesel engine heat rate assumed to be 7,000 Btu/hp-hr.
3. Fuel gas has a heat content of 1,020 Btu/scf and H_2S of 50 ppmv.
4. The Solar Taurus 70 turbine has a heat rate of 10,100 Btu/kW-hr.
5. Higher potential SO_2 emissions result from dual fired turbines firing 8,760 hr/yr on fuel gas, than firing 1,000 hr/yr on ULSD and 7,760 hr/yr on fuel gas.

TABLE OF CONTENTS

EXECUTIVE SUMMARY 1

1.0 INTRODUCTION 6

1.1 Project Summary 6
1.2 Measurement Methods 11

1.2.1. Continuous NO_2, O_3, CO and SO_2 Monitoring 13

1.2.2 Continuous PM_{10} and $PM_{2.5}$ Monitoring 13

1.2.3 Meteorological Monitoring 14

1.3 Variations from QAPP 14

2.0 STATION PERFORMANCE SUMMARY 17

2.1 Significant Project Events 17
2.2 Missing, Invalid, and Adjusted Data 18
2.3 Network Data Completeness 19
2.4 Precision Statistics 23

2.4.1 Monitoring Network Precision Statistics 23

2.4.2 Analytical Laboratory Precision Statistics 23

2.4.3 Analytical Laboratory Precision Statistics for Lead Analysis 23

2.5 Accuracy Statistics 36

2.5.1 Instrument Calibration Statistics 36

2.5.2 Independent Quality Assurance Audits 42

3.0 MONITORING DATA NETWORK SUMMARY 51

3.1 Air Quality Data Summary 51
3.2 Meteorological Data Summary 60

3.2.1 Wind Speed (WS) and Wind Direction (WD) Climatology 60

3.2.2 Temperature Climatology 70

EXECUTIVE SUMMARY

On behalf of ExxonMobil Development Company (EMDC), HCG, Inc., d/b/a Hoefler Consulting Group, operates the Point Thomson Unit Ambient Air and Meteorological Monitoring Station located within the Point Thomson Unit on the North Slope of Alaska. Ambient air and meteorological monitoring is being conducted in the Point Thomson Unit to measure air quality impacts associated with operation of the Point Thomson, and to collect Prevention of Significant Deterioration (PSD) quality data to support air quality engineering and permitting projects, and demonstrate compliance with applicable regulatory and environmental requirements.

The ambient air and meteorological monitoring station is located on the southeast corner of the Central Pad Facility located approximately 29 km east of Badami, Alaska. The Point Thomson station measures ambient air concentrations of nitrogen dioxide (NO_2), ozone (O_3), sulfur dioxide (SO_2), carbon monoxide (CO), particulate matter less than 10 micrometers (µm) in diameter (PM_{10}) and less than 2.5 µm in diameter ($PM_{2.5}$), and various meteorological parameters.

The Point Thomson Unit Ambient Air and Meteorological Monitoring Program began on September 1, 2009 and will continue through at least August 31, 2010. This report covers the first monitoring year of the Point Thomson Ambient Air and Meteorological Monitoring Program. The objective of this monitoring program is to collect ambient air quality data to support atmospheric dispersion modeling and baseline studies for obtaining environmental permits required for the anticipated activities associated with the Point Thomson Program. The data may also be used for engineering design and environmental baseline studies. The monitoring project results show compliance with the 18 Alaska Administrative Code 50 (18 AAC 50) standards for NO_2, O_3, SO_2, CO, PM_{10}, and $PM_{2.5}$.

Table E-1 provides a summary of quarterly and annual measured data for the monitored pollutants and the respective ratios of measured pollutants to National Ambient Air Quality Standards and Alaska Ambient Air Quality Standards (NAAQS/AAAQS). Tables E-2 and E-3 provide monthly and annual valid data capture hours and the percent data capture, respectively, for the Point Thomson meteorological monitoring station. The Point Thomson meteorological monitoring station met all PSD requirements during the monitoring year. NO_2 and $PM_{2.5}$ will not be reported in this first annual data report. These two parameters will be reported in subsequent and separate reports.

Table E-1. Ambient Air Quality Standards and Point Thomson Unit Ambient Air Monitoring Data

Pollutant	National and Alaska Ambient Air Quality Standards (NAAQS/AAAQS)		Point Thomson Ambient Air Monitoring – Pollutant Data (ppm)						
	Primary Standard	Secondary Standard	Averaging Period	Quarter A	Quarter B	Quarter C	Quarter D	Annual	% of NAAQS/ AAAQS

1.0 INTRODUCTION

1.1 Project Summary

The Point Thomson Project involves construction and operation of a processing facility to recover condensate liquids from the Point Thomson reservoir. To support this project, EMDC is conducting ambient air and meteorological monitoring at the Central Pad Facility located in Point Thomson, Alaska. The monitoring program is collecting at least one year of Prevention of Significant Deterioration (PSD) quality data to support air permitting efforts.

For some pollutants, air emissions dispersion modeling will be required to determine the predicted ambient impacts. The data being collected at the Central Pad Facility will provide at least one year of representative surface observations for use in dispersion modeling and for future air quality permitting. The collection of up to 12 contiguous months of ambient air data and complementary meteorological data will include:

The Point Thomson station collects the following ambient air data

- Nitrogen dioxide (NO_2)
- Carbon monoxide
- Sulfur dioxide (SO_2)
- Ozone (O_3)
- Inhalable particulate matter less than 10 microns (PM_{10})
- Inhalable particulate matter less than 2.5 microns ($PM_{2.5}$)

The Point Thomson station collects data for the following meteorological parameters:

- Air temperature (degrees Celsius [°C])
- Vertical temperature difference (ΔT, “Delta T” (degrees Celsius [°C]))
- Horizontal wind speed (meters per second [m/s])
- Horizontal wind direction (degrees [°])
- Horizontal wind direction standard deviation (wind sigma [σ_θ])
- Relativity humidity (%)
- Solar radiation (Watts per square meter [W/m^2])
- Barometric pressure (millibar [mb])
- Precipitation (millimeters [mm])

The monitoring year began in September 2009 and will continue through at least August 31, 2010 for all parameters and February 2011 for specific parameters. The monitoring site for the Point Thomson Project was selected in a manner consistent with PSD criteria for surface ambient air and meteorological data collection as outlined in the *Meteorological Monitoring*

Guidance for Regulatory Modeling Applications, Section 3 (EPA-454/R-99-005) and *Ambient Monitoring Guidelines for Prevention of Significant Deterioration (PSD), Section 3* (EPA 450/4-87-007). Representatives from HCG and EMDC made a preliminary site visit to the monitoring location in May 2009 to identify a suitable location for the meteorological and ambient air monitoring station. On August 6, 2009 ADEC representatives confirmed by e-mail that the chosen site was appropriate for representing the area meteorological and ambient air conditions. If dispersion modeling demonstrates emissions from the facility will cause ambient impacts that are greater than the applicable significant impact levels (SILs) of 18 Alaska Administrative Code (AAC) 50.215(d), Table 5, then, the data being collected at the Central Pad Facility will be representative of baseline conditions on a pollutant-by-pollutant basis. Consistent with 40 CFR 51, Appendix W, Section 8.2.2.a,

The ambient air and meteorological monitoring station is located on the southeast corner of the Central Pad Facility located approximately 29 kilometers (km) east of Badami, Alaska. Figure 1-1 is a site location map for the Point Thomson Unit monitoring station. Figures 1-2 and 1-3 provide a higher resolution map and an aerial photograph, respectively, of the monitoring site. Figure 1-4 is a photograph of the Point Thomson Unit station. NO_2 and $PM_{2.5}$ will not be reported in this first annual data report. These two parameters will be reported in subsequent and separate reports.

Figure 1-3. Photo of the Point Thomson Monitoring Station

1.2 Measurement Methods

The Point Thomson Unit Ambient Air and Meteorological Monitoring Program consist of 1-hour average ambient NO_2, O_3, SO_2, CO, $PM_{2.5}$, and PM_{10} concentrations, and 1-hour average meteorological measurements collected starting September 1, 2009. The specific pollutant monitoring methods used for this project at the Point Thomson Unit air monitoring stations consisted of automated NO_2, O_3, SO_2, CO analyzers, and continuous PM_{10} and $PM_{2.5}$ monitors. Additionally, sensors for the measurement of wind speed, wind direction, ambient temperature, vertical temperature difference, and solar radiation were used to collect meteorological data.

Table 1-1 provides a summary of the measurement methods and parameters used for the Point Thomson Ambient Air Monitoring Program.

NO_2 and $PM_{2.5}$, will not be reported in this first annual data report. These two parameters will be reported in subsequent and separate reports.

Table 1-1. Point Thomson Ambient Air Monitoring Measurement Methods

Parameter	Sensor Manufacturer/ Model Number	Measurement Method	Representativeness	Precision (using one point QC checks)	Accuracy	Method Detection Limits	Completeness
Nitrogen Dioxide	Thermo 42i	Gas-phase chemiluminescence	EPA reference method RFNA-1289-074 40 CFR 53	90% CL CV ≤10%	≤ 15% for each audit concentration (per quarter)	0.4 ppb	80% per quarter, 4 consecutive quarters
Carbon Monoxide	Thermo 48i	Non-dispersive Infrared (NDIR) absorbance spectroscopy	EPA equivalent method RFCA-0981-054 40 CFR 53	90% CL CV ≤10%	≤ 15% for each audit concentration (per quarter)	40 ppb	80% per quarter, 4 consecutive quarters
Sulfur Dioxide	Thermo 43i	Ultraviolet (UV) fluorescence spectroscopy	EPA equivalent method EQSA-0486-060 40 CFR 53	90% CL CV ≤10%	≤ 15% for each audit concentration (per quarter)	0.5 ppb	80% per quarter, 4 consecutive quarters
Ozone	Teledyne 400E	Photometric Ambient O_3 Analyzer	EPA equivalent method EQOA-0992-087 40 CFR 53	90% CL CV ≤7%	≤ 15% for each audit concentration (per quarter)	0.5 ppb	80% per quarter, 4 consecutive quarters
$PM_{2.5}$	Met One Bam-1020	Beta Attenuation Detector	EPA equivalent method EQPM-0308-170 40 CFR 53	≤3 µg/m^3 difference between audit samples (per quarter)	±5% (±0.83 LPM) of designed value ±4% (±0.67 LPM) of NIST traceable flow standard (per quarter)	≤ 1.0 µg/m^3	≥80% (per quarter)
PM_{10}	Met One Bam-1020	Beta Attenuation Detector	EPA equivalent method EQPM-0798-122 40 CFR 53	N/A	±5% (±0.83 LPM) of designed value ±4% (±0.67 LPM) of NIST traceable flow standard (per quarter)	≤ 1.0 µg/m^3	≥80% (per quarter)
$PM_{2.5}$ – QC Collocated	Partisol 2000-FRM	Single-filter Manual Sampler	EPA equivalent method RFPS-0498-117 40 CFR 53	N/A	±5% (±0.83 LPM) of designed value ±4% (±0.67 LPM) of NIST traceable flow standard (per quarter)	2 µg/m^3	≥80% (per quarter)

1.2.1. Continuous NO_2, O_3, CO and SO_2 Monitoring

The pollutant monitoring methods used for this project are designated by the U.S. Environmental Protection Agency (EPA) as either Automated Reference Methods or Manual Reference Methods, consistent with the *Ambient Monitoring Guidelines for Prevention of Significant Deterioration* (EPA-450/4-87-007) or equivalent methods, and the requirements of the state of Alaska Department of Environmental Conservation (ADEC).

A Thermo Model 42i nitrogen oxides ($NO/NO_2/NO_x$) analyzer was used to measure NO_2. EPA has designated this analyzer as an Automated Equivalent Method (RFNA-1289-074) for NO_2 monitoring. In this method, NO_2 is determined by the difference between directly measured nitric oxide (NO) and total nitrogen oxides (NO_x). NO_2 will not be reported in this first annual data report, but it will be reported in a separate report.

Ozone was measured using a Teledyne Model 400E U.V. Photometric Ambient O_3 analyzer. EPA has designated this analyzer as an Automated Reference Method (EQOA-0992-087) for O_3 monitoring.

SO_2 will be measured using a Thermo Model 43i Pulsed Fluorescence SO_2 analyzer. EPA has designated this analyzer as an Automated Reference Method (EQSA-0486-060) for SO_2 monitoring.

A Thermo Model 48i carbon monoxide analyzer was used to measure CO. EPA has designated this analyzer as an Automated Reference Method (RFCA-0981-054) for CO monitoring.

1.2.2 Continuous PM_{10} and $PM_{2.5}$ Monitoring

PM_{10} was determined using a Met One Instruments—Model BAM-1020 (PM_{10}) Monitor including the BX 802 sampling inlet. EPA has designated this monitor as an Automated Equivalent Reference Method (EQPM-0798-1222) for PM_{10} measurements.

$PM_{2.5}$ was determined using a Met One Instruments—Model BAM-1020 ($PM_{2.5}$) FEM Configuration Monitor with a BGI VSCC™ Very Sharp Cut Cyclone particle size separator. EPA has designated this monitor as an Automated Equivalent Reference Method (EQPM-0308-170) for $PM_{2.5}$ measurements. The BAM-1020 sampling technology exceeds US EPA Class III $PM_{2.5}$ FEM standards for additive and multiplicative bias and is considered to meet the sampling frequency requirements adopted by EPA for the National Ambient Monitoring Stations (NAMS) network and the State/Local Ambient Monitoring Stations (SLAMS) network.

Additionally, quality control (QC) procedures for $PM_{2.5}$ include a separate "collocated," $PM_{2.5}$ sampler. The collocated $PM_{2.5}$ sampler is a Federal Reference Method (FRM) Partisol FRM Model 2000 manual sampler with a BGI VSCC™ Very Sharp Cut Cyclone particle size

separator. EPA has designated this monitor as FRM (RFPS-0498-117, 63 FR 18911 and 67 FR 15567) for $PM_{2.5}$ measurements. Collocated $PM_{2.5}$ monitors are required for PSD monitoring stations as per 40 CFR 58 Appendix A Section 3.2.5.5. $PM_{2.5}$ will not be reported in this first annual data report, but it will be reported in a separate report.

1.2.3 Meteorological Monitoring

The meteorological sensors deployed for the Point Thomson Ambient Air and Meteorological Program meet the performance specification requirements contained in *Meteorological Monitoring Guidance for Regulatory Modeling Applications* (EPA-454/R-99-005).

Table 1-2 lists each parameter measured at the Point Thomson station and includes the sensor manufacturer and model number, measurement range, accuracy, sampling frequency, and sample averaging period. All instruments meet or exceed the EPA PSD requirements for range accuracies, thresholds, response times, resolutions, damping ratios, and other measures of instrument performance.

1.3 Variations from QAPP

Table 1-3 lists the variations from the previously submitted Point Thomson Ambient Air and Meteorological Monitoring Quality Assurance Project Plan (QAAP) during the 2009-2010 monitoring year.

Table 1-2. Meteorological Measurement Methods at the Point Thomson Station

Meteorological Parameter	Manufacturer and Model	Measurement Method	Manufacturer Specified Accuracy	EPA Required Accuracy[1]	EPA Required Resolution[1]	Detectability Data Completeness[1]	Sampling Frequency	Averaging Period
Ambient Temperature and Vertical Temperature Difference	Climatronics 102096	Extended Range Thermistor	±0.10°C	±0.5°C (Ambient Temperature), ±0.1°C (Temperature Difference)	0.1°C (Ambient Temperature), 0.02°C (Temperature Difference)	90% per monitoring quarter	1 second	1 hour
Wind Speed	RM Young 05305 AQ	Light-Weight Propellor	±0.2 m/s	±0.2m/s or ±5%	0.1 m/s	90% per monitoring quarter	1 second	1 hour
Wind Direction	RM Young 5305 AQ	Light-Weight Vane	±3 degrees	±5 degrees	1.0 degree	90% per monitoring quarter	1 second	1 hour
Barometric Pressure	Vaisala PTB110	Silicon Capacitive Sensor	±0.3 mbar	±3 mbar	0.5 mbar	90% per monitoring quarter	1 second	1 hour
Relative Humidity	Climatronic 102273	Thin-polymer capacitor	±1%	±1.5°C or 7% RH	0.1°C[2]	90% per monitoring quarter	1 second	1 hour
Solar Radiation	Eppley-PSP	Precision Spectral Pyranometer	±2%	±5% of observed	10 W/m^2	90% per monitoring quarter	1 second	N/A[3]
Precipitation	NovaLynx 260-2500E	Tipping Bucket	±1.0% <3.0"/hr ±3.0% < 6.0 "/hr	±10% of observed or ±0.5 mm	0.3 mm	90% per monitoring quarter	N/A[4]	N/A[4]

[1] Referenced in *Meteorological Monitoring Guidance for Regulatory Modeling Applications* (EPA-454/R-99-005).
[2] Values are given in terms of dew point temperature in guidance document(EPA-454/R-99-005).
[3] Instantaneous pressure measurements are sampled once per hour.
[4] Instantaneous precipitation measurements are collected by the datalogger and subsequently summed on an hourly basis.

Table 1.3. Variations from the QAPP

QAPP Statement	Variation from the QAPP
The Point Thomson station measures ambient air concentrations of nitrogen dioxide (NO_2), ozone (O_3), and sulfur dioxide (SO_2), carbon monoxide (CO), various meteorological parameters, and measures particulate matter less than 10 micrometers (µm) in diameter (PM_{10}) and less than 2.5 µm in diameter ($PM_{2.5}$).	This Annual Data Report will not include nitrogen dioxide (NO_2) data or particulate matter less than 2.5 µm in diameter ($PM_{2.5}$).

2.0 STATION PERFORMANCE SUMMARY

2.1 Significant Project Events

Table 2-1 summarizes the sequence of significant events at the Point Thomson Unit Monitoring Program.

Table 2-1. Chronology of Significant Events at Point Thomson

Date	Event
May 27, 2009	Initial monitoring site selection trip to Point Thomson Central Pad.
July 9, 2009	Alan Schuler of ADEC approves the site location and use of a 55-ft tower for the meteorological measurements.
August 17-25, 2009	Installation of monitoring station and initial station multi-point calibration checks and mass flow meter calibrations (all gas analyzers passed)
September 1, 2009	Beginning of 2009-2010 monitoring year.
September 1-2, 2009	Conducted initial (Quarter A) performance audit for gas analyzers, PM monitors and meteorological equipment (all passed).
September 15, 2009	Ozone calibrator configuration/malfunction problems were corrected this day. Precision calibrations failed QC standards prior to this day. Daily calibrations were consistently passing during this period.
October 6, 2009	Conducted Quarter A multi-point calibration checks (all gas analyzers passed).
October 7, 2009	Meteorological tower replaced with more heavy duty model. Wind direction alignment was confirmed before & after replacement
December 7-8, 2009	Quarter B gas analyzer and PM sampler audit (all passed).
December 8-9, 2009	Quarter B multi-point calibration checks and mass flow meter calibration (all gas analyzers passed)
January 1, 2010	Shelter Temperature problems occurred because of station heater failure during a severe arctic storm. Unable to consistently attain temperature control until January 15th. Significant analyzer downtime occurred during this period.
February 2, 2010	Noted power failure. Shelter temperature dropped to 10°C
March 17-18, 2010	Quarter C performance audit for gas analyzers, PM samples and meteorological equipment (all passed).
April 27-28, 2010	Quarter C multi-point calibration checks and mass flow meter calibration (all gas analyzers passed).
June 1, 2010	SO_2 analyzer starts having intermittent sample flow problems and infrequent calibration failures. Determined to be a partially plugged capillary which was replaced during July 6, 2010 site visit.
June 26-27, 2010	Conducted meteorological equipment calibration (all passed).
June 27-July 6, 2010	Ozone calibrator removed for recertification.

Date	Event
July 30-31, 2010	Conducted meteorological equipment audit (all passed).
August 17-18, 2010	Conducted final (Quarter D) performance audit for gas analyzers, PM monitors and meteorological equipment (all passed).
August 17-18, 2010	Conducted meteorological equipment calibration (all passed).
August 18, 2010	Quarter D multi-point calibration checks and mass flow meter calibration (all gas analyzers passed).
August 31, 2010	End of the 2009-2010 monitoring year.

2.2 Missing, Invalid, and Adjusted Data

The data for the Point Thomson ambient air and meteorological monitoring station were carefully reviewed during the quality assurance process. Some data were removed as a result of planned site activities, including data collected during station system and performance audits and calibrations. Data known or suspected to be invalid according to EPA criteria listed in table 2-2 have been flagged in the data set.

Precision checks are conducted automatically approximately every seven days between 03:00 and 04:00. Beginning in February the precision checks were changed to occur between 07:00 and 08:00. Less than 45 minutes of valid ambient air quality data are collected during these times. Therefore, O_3, SO_2, and CO data were invalid for these hours. The shelter temperature was continuously monitored throughout the monitoring year. Any measurements collected during periods when the shelter temperature drifted outside of the range of 20 to 30 degrees Celsius for O_3, SO_2, and CO was flagged as invalid and removed from the data set per the EPA reference method designation temperature range. Data was also flagged during periods when the standard deviation of the daily shelter temperature was greater than 2 degrees Celsius and any suspect data collected during these periods were removed from the data set.

Table 2-2 lists the quantities of Point Thomson meteorological data that were flagged according to EPA criteria, yet not removed from the refined data set. All flagged data were carefully examined, but generally remained in the refined data set unless dictated by certain circumstances. In some instances, technical difficulties occurred during the monitoring year that included planned and unplanned power outages, shelter temperatures below the acceptable operating range, and faulty station components. Data validation criteria, provided in the monitoring program QAPP, were used to challenge the validity of ambient air measurements. All meteorological data was validated only after being screened by the

criteria listed in Table 8-4 of *Meteorological Monitoring Guidance for Regulatory Modeling Applications* (EPA-454/R-99-005).

2.3 Network Data Completeness

Data completeness is a measure of the amount of data actually collected compared to the amount of data that could have been collected. Data completeness was calculated by dividing the number of valid hours of data by the total number of hours during the monitoring period. The data quality objective (DQO) for data completeness for air quality data is 80 percent per calendar quarter, and 90 percent for meteorological data per calendar quarter.

Annual and quarterly data completeness is provided in Tables 2-3 and 2-4. Calculations for determining data completeness are provided in Appendix A. The Point Thomson ambient air and meteorological monitoring station met all PSD requirements during the monitoring year.

Table 2-2. Percentage of Final Data Set Flagged

Parameter	Flagging Criteria[1]	Percent Flagged
Wind Speed (RM Young)	Value is < 0 m/s, > 25 m/s	0.1%
	< 0.1 m/s variation for 3 consecutive hours	1.8%
	<0.5 m/s variation for 12 consecutive hours	0.2%
Wind Direction (RM Young)	Value is < 0°, > 360°	0.0%
	<1° variation over 3 consecutive hours	3.3%
	< 10° variation over 18 consecutive hours	6.7%
2-m Temperature	> 5°C variation from previous hour	0.3%
	< 0.5°C variation for 12 consecutive hours	2.8%
	Value is > record high, < record low	0.0%
10-m Temperature	> 5°C variation from previous hour	0.3%
	< 0.5°C variation for 12 consecutive hours	4.3%
	Value is > record high, < record low	0.0%
Temperature Difference, ΔT	Value is > 0.8°C (>0.1°C/m) during the daytime	0.7%
	Value is < -0.8°C d (<-0.1°C/m) during the night	0.2%
	Value is > 5°C, < -3°C	0.4%
Relative Humidity (Dew Point Temperature)[2]	Value is > ambient temperature	0.0%
	> 5°C variation from previous hour	1.0%
	< 0.5°C variation for 12 consecutive hours	1.8%
	Equals ambient temperature for 12 consecutive hours	0.3%
Solar Radiation	> 0 W/m^2 at night (Night time = 1hr before/after sunrise/sunset[3])	0.0%
	Greater than the maximum possible value for date and latitude	0.0%
Barometric Pressure	> 1060 mb (sea level)	0.0%
	< 940 mb (sea level)	0.0%
	> 6 mb variation for 3 consecutive hours	0.4%
Precipitation	> 25 mm in one hour	0.0%
	> 100 mm in 24 hours	0.0%
	< 50 mm in one month	0.0%

[1] Based upon Table 8-4: Suggested Data Screening Criteria in *Meteorological Monitoring Guidance for Regulatory Modeling Applications* (EPA-454/R-99-005).
[2] Guidance document provides criteria relative to dew point temperature.
[3] Defined as when the leading or trailing edge of the sun passes the horizon, with the know exception of the "midnight sun" referring to the phenomena of 24 consecutive hours of sunlight north of the Arctic Circle or south of the Antarctic Circle.

Table 2-3. Annual and Quarterly Data Completeness at Point Thomson

Period	Pollutants			
	O_3	CO	SO_2	PM_{10}
September 2009	50.8%[2]	93.5%	93.6%	96.7%
October 2009	95.4%	95.4%	95.6%	90.3%
November 2009	97.6%	97.6%	97.6%	100%
Quarter A	**81.5%**	**95.5%**	**95.6%**	**95.6%**
December 2009	97.8%	97.4%	97.6%	100%
January 2010	58.9%[3]	58.9%[3]	50.8%[3]	61.3%[3]
February 2010	94.9%	95.1%	95.1%	100%
Quarter B	**83.5%**	**83.4%**	**80.7%**	**86.7%**
March 2010	96.1%	96.1%	96.1%	100%
April 2010	77.4%[4]	98.3%	98.3%	100%
May 2010	93.5%	93.5%	91.3%	100%
Quarter C	**89.1%**	**96.0%**	**95.2%**	**100%**
June 2010	92.8%	92.9%	56.4%[5]	100%
July 2010	97.2%	96.0%	95.6%	100%
August 2010	96.4%	96.4%	96.4%	100%
Quarter D	**95.5%**	**95.1%**	**83.1%**	**100%**
Monitoring Year[1]	**87.4%**	**92.5%**	**88.7%**	**95.6%**

[1] September 1, 2009 through August 31, 2009
[2] Due to initial instrument configuration, valid data capture began on September 14, 2009.
[3] Due to station climate control system malfunction.
[4] Due to instrument malfunction, repaired April 27, 2010.
[5] Due to three calibration failures.

Table 2-3 (continued). Annual and Quarterly Data Completeness at Point Thomson

Period	Meteorological Parameters

2.4 Precision Statistics

2.4.1 Monitoring Network Precision Statistics

Precision statistics were determined using the methods outlined in 40 Code of Federal Regulation, Part 58 (40 CFR 58), Appendix A. Quarterly precision results for each criteria pollutant are provided in Tables 2-4 through 2-6. Valid precision data were collected at least once every two weeks, meeting the critical validation criteria outlined in the monitoring program QAPP.

2.4.2 Analytical Laboratory Precision Statistics

Not applicable

2.4.3 Analytical Laboratory Precision Statistics for Lead Analysis

Not applicable.

2.5 Accuracy Statistics

The ambient air and meteorological monitoring systems are subjected to periodic calibrations and independent quality assurance performance audits. All calibration and audit equipment are documented as traceable to authoritative standards. The purpose of these calibration and audit checks is to challenge the monitoring systems with known inputs and to verify that each instrument response is accurate to within established tolerances.

2.5.1 Instrument Calibration Statistics

Automated single-point calibrations were performed on a daily basis on all pollutant analyzers throughout the monitoring year. The single-point calibrations consisted of challenging each instrument response with air scrubbed of all pollutants ("zero air") and air containing a National Institute of Standards and Technology (NIST) traceable standard gas concentration equal to 80 percent of the instrument's upper range limit (URL). When single point calibration zero or span drift limits were exceeded the project manager was notified so corrective action could be taken.

Table 2-7 provides data accuracy for the single-point calibration checks for each applicable measurement parameter. Single-point calibration data for each parameter and parameter quality control (QC) performance statistics are provided in Appendix C.

Multi-point calibrations were performed during the initialization of the monitoring year and on a biannual basis as recommended by EPA (EPA-454/R-98-004). Additionally, multi-point calibrations were conducted under specific circumstances, including indication of analyzer malfunction, repairs or service that affected its calibration, and following significant interruptions in station operations. Multi-point calibrations consisted of challenging each instrument response with air scrubbed of all pollutants ("zero air") and at least four concentrations spanning 80 to 90 percent of the URL.

Table 2-8 provides a summary of the multi-point calibrations conducted during the first year of ambient air monitoring. All points of the multi-point calibration must be within $\pm$ 2 percent of the full-scale best-fit straight line to be considered acceptable. Complete individual multi-point calibration data and results are provided in Appendix C.

Table 2-9 summarizes the quarterly quality control checks of the PM_{10} sampler. These manual QC checks are conducted by HCG or on-site personnel and the data are transmitted to the HCG Anchorage office.

Table 2-7. Data Accuracy Table

Period	Ozone, O_3				
	Standard Concentration (ppm)[1]	Number of Valid Span Checks	Average Percent Difference[2]	Standard Deviation of Percent Difference	Maximum Absolute Percent Difference
September 2009	0.40 - 0.45	29	0.3%	2.9%	9.1%

2.5.2 Independent Quality Assurance Audits

The meteorological performance audit involves challenging the sensors with known inputs or by using calibrated instruments collocated with the sensor. For each reading, the difference between the station value and the expected value is compared with established PSD limits to assess the accuracy of the sensor.

The gas analyzers performance audit acceptance criterion for an individual analyzer is that the mean absolute difference between the audit gas concentration and analyzer response is equal to or less than 15 percent. Linear regression acceptance criteria of the best-fit line of individual pollutant parameter audit points are: a) the slope is greater than or equal to 0.85 and less than or equal to 1.15, b) the y-intercept is less than or equal to 3 percent of the full scale of the analyzer, and c) the R-squared value is greater than or equal to 0.995.

The performance audit of PM_{10} monitor challenges the flow rate of the monitor against independent instruments that are calibrated and traceable to National Institute of Standards and Technology (NIST) transfer standards. An audit of the PM_{10} is conducted using an audit orifice transfer standard (BGI Delta Cal or equivalent).

The performance audits were performed on all station monitors at Point Thomson to check each meteorological sensor and PM monitor operation against certified audit equipment and to challenge each gaseous analyzer against at least one audit gas of known concentration. All meteorological sensors, gaseous analyzers and PM_{10} monitor passed their respective audits with the exception of the secondary back up solar instrument in the fourth quarter audit.

The results of the meteorological performance audits are presented in Tables 2-10 through 2-13. The results of the gas analyzers performance audits are presented in Tables 2-14 to 2-16. The results of the PM_{10} performance audits are presented in Table 2-17. All complete performance audit reports are available in Appendix C.

Table 2-10. September 1 and 2, 2009 Performance Audit Summary

Parameter	Limit	Units	Max Error	Status
Datalogger Time	≤ ±10:00	Min:Sec	00:08	Pass

3.0 MONITORING DATA NETWORK SUMMARY

3.1 Air Quality Data Summary

Table 3-1 provides quarterly and annual averages of the criteria pollutant concentrations measured from September 1, 2009 through August 31, 2010 and compared to national and Alaska air quality standards (NAAQS/AAAQS). The highest and second highest critical pollutant concentrations are also provided in Tables 3-1 and 3-2 and compared to the respective primary and secondary air quality standards.

Figure 3-1 provides plots of the 8-hour average O_3 concentrations at Point Thomson throughout the monitoring year and the respective NAAQS/AAAQS standard for comparison. The maximum 8-hour average O_3 concentration at the Point Thomson Unit station was 0.043 ppm (84.4 $\mu g/m^3$) recorded on January 23 and 24, 2010 and also on April 12, 2010. This concentration was 57.5 percent of the NAAQS/AAAQS standard of 0.075 ppm (150 $\mu g/m^3$).

Figures 3-2 and 3-3 provide respective annual time series of 24-hour average and 3-hour average SO_2 concentrations and the respective NAAQS/AAAQS standard for comparison. The maximum 24-hour average SO_2 concentration at the Point Thomson Unit station was 0.009 ppm (23.5 $\mu g/m^3$), or 6.6 percent of the NAAQS/AAAQS standard of 0.14 ppm (365 $\mu g/m^3$) recorded on November 29, 2009 and January 13, 2010. The maximum 3-hour average SO_2 concentration at the Point Thomson Unit station was 0.025 ppm (65.5 $\mu g/m^3$), or 5.1 percent of the NAAQS/AAAQS standard of 0.50 ppm (1.3 mg/m^3) measured on November 29, 2009. The annual average SO_2 concentration at the Point Thomson Unit station was 0.001 ppm (2.6 $\mu g/m^3$), or 2.9 percent of the NAAQS/AAAQS SO_2 standard of 0.03 ppm (80 $\mu g/m^3$). Figure 3-4 provides plots of the 1-hour average SO_2 concentrations at Point Thomson throughout the monitoring year and the respective NAAQS/AAAQS standard for comparison. The maximum 1-hour average SO_2 concentration at the Point Thomson Unit station was 0.029 ppm (75.9 $\mu g/m^3$), or 38.8 percent of the NAAQS/AAAQS standard of 0.075 ppm (200 $\mu g/m^3$) measured on November 29, 2009.

Figures 3-5 and 3-6 provide respective plots of the 8-hour average and 1-hour average CO concentrations and the respective NAAQS/AAAQS standard for comparison. The maximum 8-hour average CO concentration at the Point Thomson Unit was 1.15 ppm (1.32 mg/m^3), or 12.8 percent of the NAAQS/AAAQS CO standard of 9 ppm (10 mg/m^3). The maximum 1-hour average CO concentration at the Point Thomson Unit was 1.9 ppm (2.18mg/m^3), or 5.4 percent of the NAAQS/AAAQS CO standard of 35 ppm (40 mg/m^3).

3.2 Meteorological Data Summary

3.2.1 Wind Speed (WS) and Wind Direction (WD) Climatology

Table 3-2 provides a statistical summary of RM Young (RMY) horizontal wind speed measurements during the first year of meteorological monitoring at the Point Thomson Unit station. The mean hourly average wind speed during the monitoring year was 6.67 meter per second (m/s). The maximum hourly average wind speed of 26.02 m/s was measured on January 1, 2010. Table 3-3 provides the mean and maximum daily wind speeds at the Deadhorse meteorological station, located approximately 84 km to the west of Point Thomson in the North Slope region near the Arctic Ocean. During the monitoring year the mean daily average wind speed at the Deadhorse airport was 5.52 m/s, while the maximum daily average wind speed was 21.01 m/s on October 22, 2009.

Table 3-2. Average and Maximum Wind Speeds at the Point Thomson Unit Station

Monitoring Period	Mean Hourly Average Wind Speed (m/s)	Maximum Hourly Average Wind Speed (m/s)
Quarter A	6.63	24.99
Quarter B	7.67	26.02
Quarter C	6.49	17.08
Quarter D	5.90	20.62
Monitoring Year	**6.67**	**26.02**

Table 3-3. Average and Maximum Wind Speeds at Deadhorse Airport

Monitoring Period	Mean Daily Average Wind Speed (m/s)	Maximum Daily Average Wind Speed (m/s)
Quarter A	4.97	21.01
Quarter B	6.25	19.67
Quarter C	5.67	16.09
Quarter D	5.19	18.33
Monitoring Year	**5.52**	**21.01**

Figure 3-7 provide the wind rose for the RMY primary wind instrument sensor "A" during the 2009-2010 monitoring year collocated at the Point Thomson Unit station. Winds were predominantly from the east, northeast, and southwest with other minor wind components. Figure 3-8 presents the quarterly wind roses for the RMY sensor. All Quarterly wind roses display a major wind component from the east and northeast direction. Quarters A, B and C wind roses display an additional major wind component from the southwest direction. Tables 3-4 through 3-8 are the annual and quarterly wind analysis tables for the RMY wind measurements.

Figure 3-9 shows the 2009-2010 year wind rose for the RMY wind sensor superimposed over a map of the Point Thomson Unit site and vicinity. The wind rose is centered over the Point Thomson Unit station and shows that, on an annual basis, winds at the site predominantly blow from the east, west, northeast and southwest.

Figure 3-9. 2009-2010 Wind Rose Superimposed on Site Map

3.2.2 Temperature Climatology

Tables 3-9 and 3-10 give the maximum and minimum daily mean temperatures, monthly mean temperatures, and maximum and minimum hourly average temperatures for the 2-meter and 10-meter temperature measurements, respectively.

The 2009-2010 annual mean temperature was -10.1°C at the 2-meter height. This annual mean temperature is slightly lower than the annual mean temperature of -9.9°C observed at the Deadhorse meteorological station from September 1, 2009 through August 31, 2010. Hourly average temperatures at the Point Thomson Unit station varied from a maximum of 23.4°C on August 2, 2010 to a minimum of -42.6°C on January 9, 2010.

Figure 3-10 provides a graph of the 2-meter and 10-meter hourly average temperatures. Considerable temperature variations occurred throughout the late-autumn and winter months. Figure 3-9 also includes a plot of average daily temperatures recorded at the meteorological monitoring station in Deadhorse, Alaska. Both the Point Thomson Unit station and the Deadhorse meteorological monitoring station are located in the North Slope Arctic climate zone.

Figure 3-11 shows a plot of the vertical temperature difference (the difference between 10-m and 2-m temperature values) during the monitoring year. The greatest positive vertical temperature difference was 8.6°C measured on January 25, 2010. The greatest negative temperature difference was -3.9°C measured on July 9, 2010.

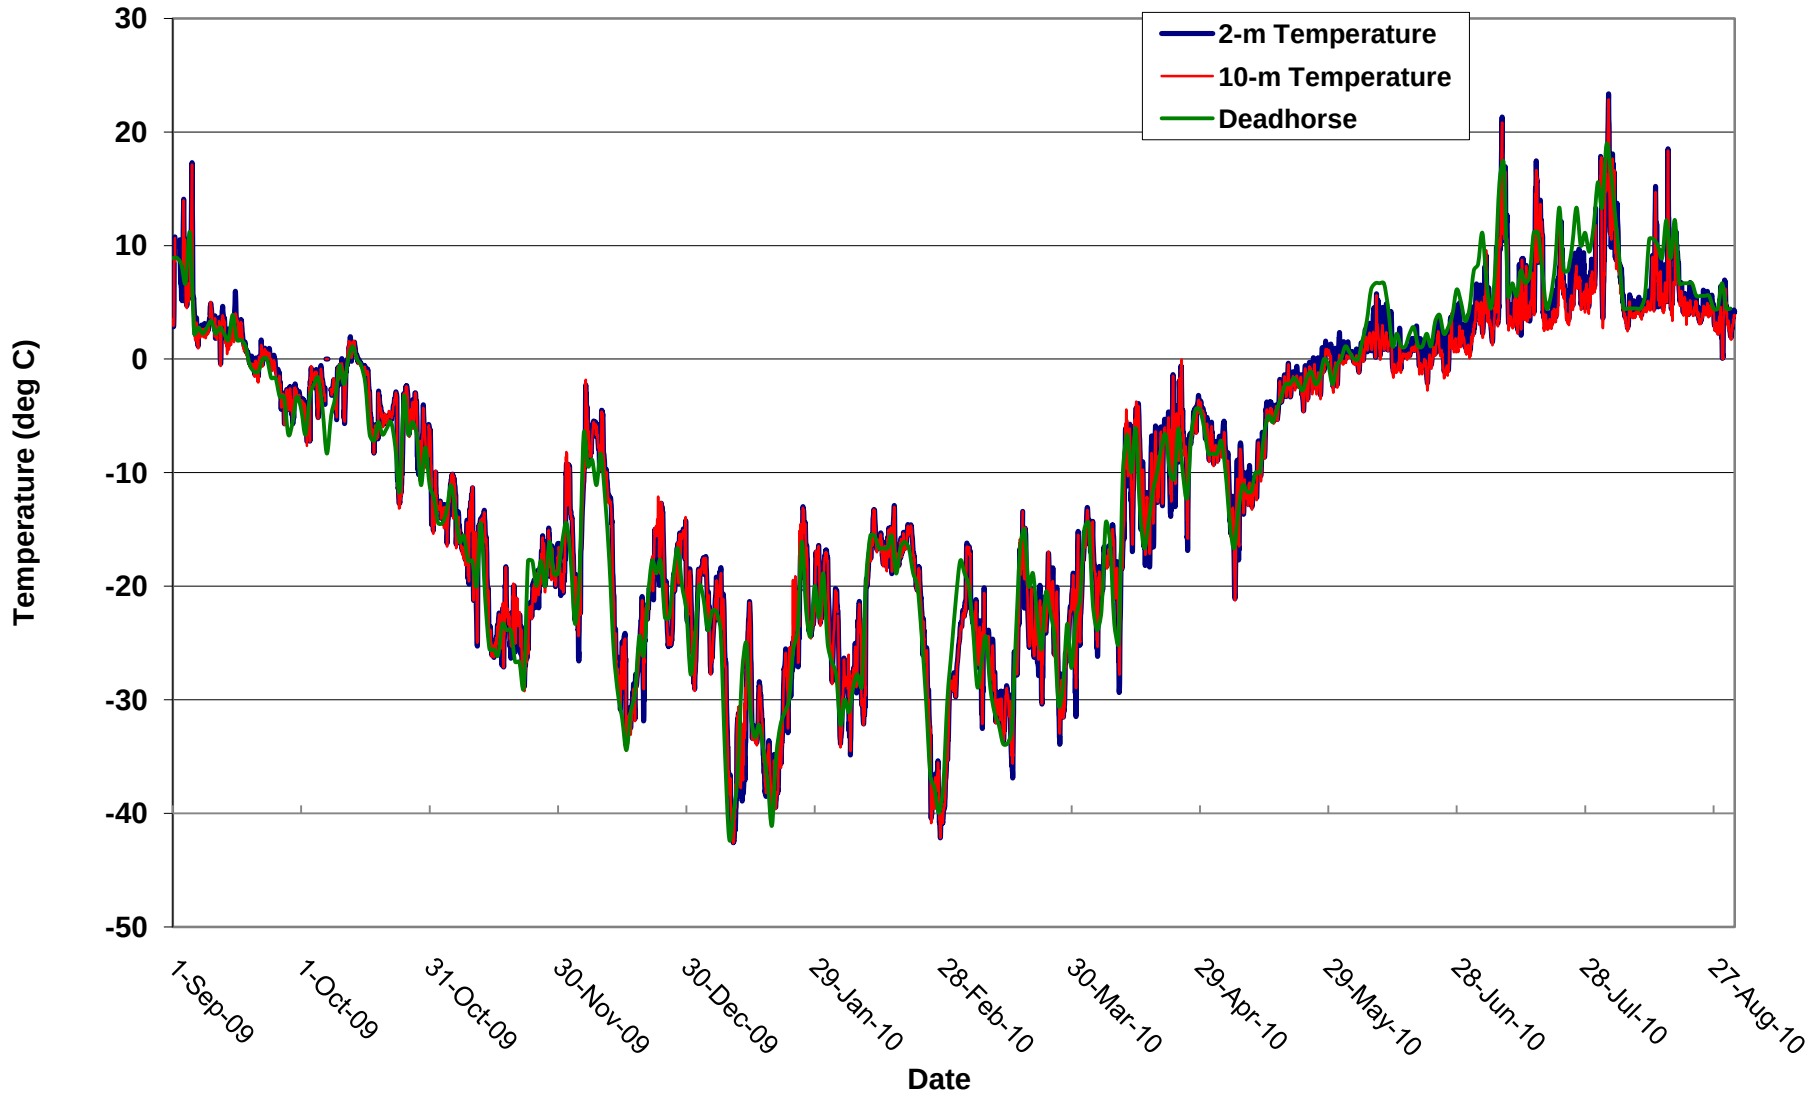

Figure 3-10. Hourly Average 2-Meter and 10-Meter Temperatures

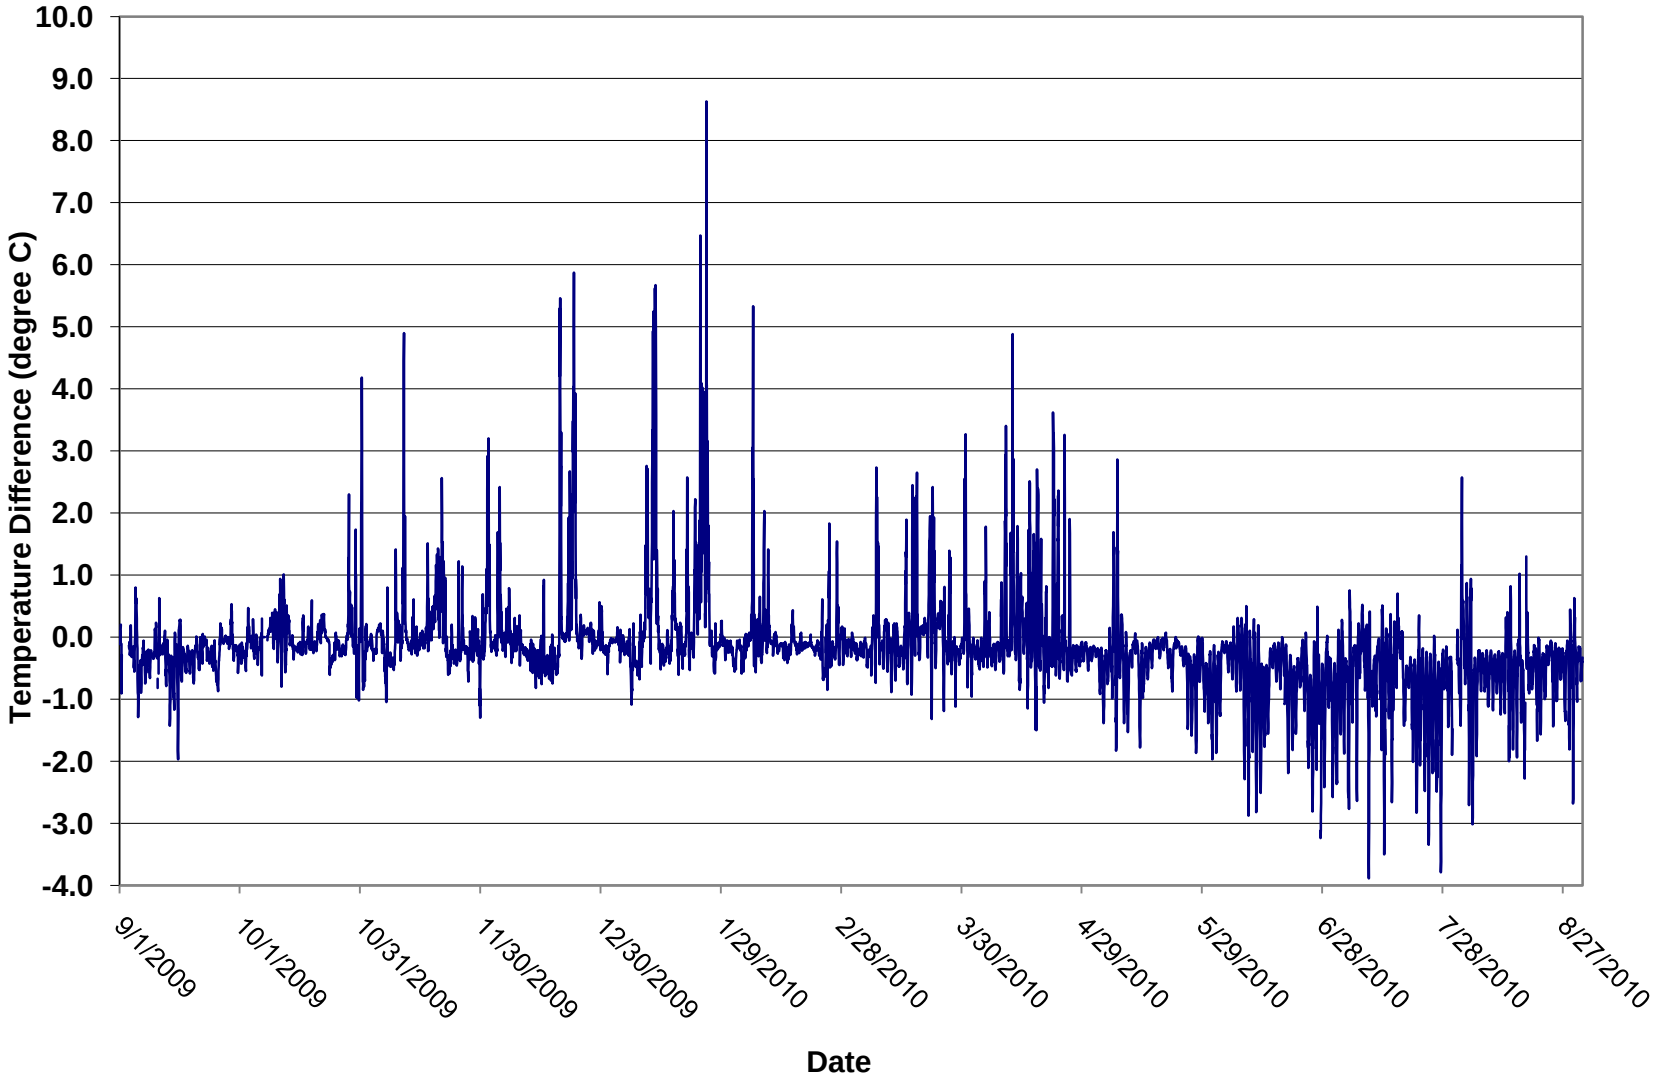

Figure 3-11. Hourly Average Vertical Temperature Difference

3.2.3 Other Meteorological Parameters

Other measured meteorological parameters include relative humidity, barometric pressure, solar radiation, and precipitation.

Table 3-11 provides a summary of the relative humidity, barometric pressure, and solar radiation at the Point Thomson Unit station during the 2009-2010 monitoring year.

Figure 3-12 is a plot of the annual hourly average relative humidity. The mean relative humidity at the Point Thomson Unit station was 85.6 percent. The minimum relative humidity was 31.1 percent, measured on July 8, 2010. The mean relative humidity at the Deadhorse meteorological station for the monitoring period was 84.1 percent.

Figure 3-13 is a plot of the annual hourly instantaneous barometric pressure. Barometric pressure varied from a minimum of 981 mb on November 11, 2009 to a maximum of 1,046 mb observed on December 4, 2009. The mean barometric pressure during the monitoring year was 1,014 mb. The mean barometric pressure at the Deadhorse meteorological station for the monitoring period was 1,014 mb.

Figure 3-14 is a plot of the annual hourly average solar radiation. The maximum hourly average solar radiation was 798.0 W/m^2 recorded on May 27, 2010. The mean hourly average solar radiation for the monitoring year was 94.7 W/m^2.

Figure 3-15 is a graph of total daily precipitation and the cumulative precipitation during the 2009-2010 monitoring year. The highest total daily precipitation was 4.75 mm measured on October 22, 2009. The maximum monthly precipitation was 33.25 mm during July 2010. The cumulative precipitation during the monitoring year was 93.25 mm.

Comprehensive hourly data tables of temperature, vertical temperature difference, wind speed, wind direction, wind sigma, relative humidity, barometric pressure, solar radiation and precipitation are also provided in Appendix D.

Table 3-11. Relative Humidity, Barometric Pressure, and Solar Radiation Summary

Period	Mean Relative Humidity (%)	Minimum Relative Humidity (%)	Mean Barometric Pressure (mb)	Minimum Barometric Pressure (mb)	Maximum Barometric Pressure (mb)	Mean Solar Radiation (W/m^2)	Maximum Solar Radiation (W/m^2)
September 2009	89.2	46.6	1,011	996	1,025	50.8	420.0

(continued on back side)

Information Needed:	Is there a range of pad locations that would meet the project's development requirements? For example, can you provide: 1. Confirmation that the existing east-pad bottomhole location is fixed and no reasonable alternative locations exist (that would provide a comparable ROI). 2. The maximum reach possible for attaining this/these target(s) considering existing drilling technology, geology, and reservoir characteristics?
Level of Detail:	Responses to the questions should contain as much detailed information as possible and clear reasoning for the response.

Comments and Rationale:

Information is needed for development of alternatives.

Level of Priority: ☐ Low ☐ Standard ☒ High ☐ Extreme

Time Sensitivity: ☐ Low ☐ Standard ☒ High

Response to Point Thomson Project EIS, RFI #63 5/5/2010

1) Confirmation that the existing east-pad bottom-hole location is fixed and no reasonable alternative locations exist (that would provide a comparable ROI).

A figure (Fig 3.1) depicting the generalized hydrocarbon accumulation within the Point Thomson reservoir has been submitted by Exxon within the current EIS application in January, 2010. In addition, a similar figure (Fig. 3-3,) was submitted by Exxon in a previous EIS application in February, 2003 depicting the approximate extent of the Point Thomson reservoir. Both figures show that the main portion of the reservoir is located one to three miles (5,000 – 16,000 feet) north of the shoreline. This is consistent with interpretations of publically available data from exploration wells previously drilled within the area.

The bottom-hole locations and number of wells ultimately drilled for full development of this resource are not fixed at this point and will depend on two main factors:

- The distribution and quality of the reservoir encountered as future development wells are drilled. Until the wells are actually drilled, a level of uncertainty still exists in regards to the internal heterogeneity of the reservoir and ultimate placement of future wells.
- The recovery method(s) ultimately employed to fully develop and produce the hydrocarbon resource. The location and number of wells would likely differ between a gas cycling development and a gas blow down development.

Given these uncertainties, it is reasonable to assume development wells may need to be drilled with horizontal departures of 10,000 to over 15,000 feet from the proposed drill pads to adequately access the hydrocarbon resources with the Thomson reservoir. A search of recent examples of drilling in similar high pressure reservoirs elsewhere in the world reveals current technology limits drilling departures to approximately 13,000 feet. From this standpoint, it is reasonable to assume that requiring the proposed drill pads to be located further south from the coastline could likely impact the ability to adequately access and develop the Point Thomson reservoir.

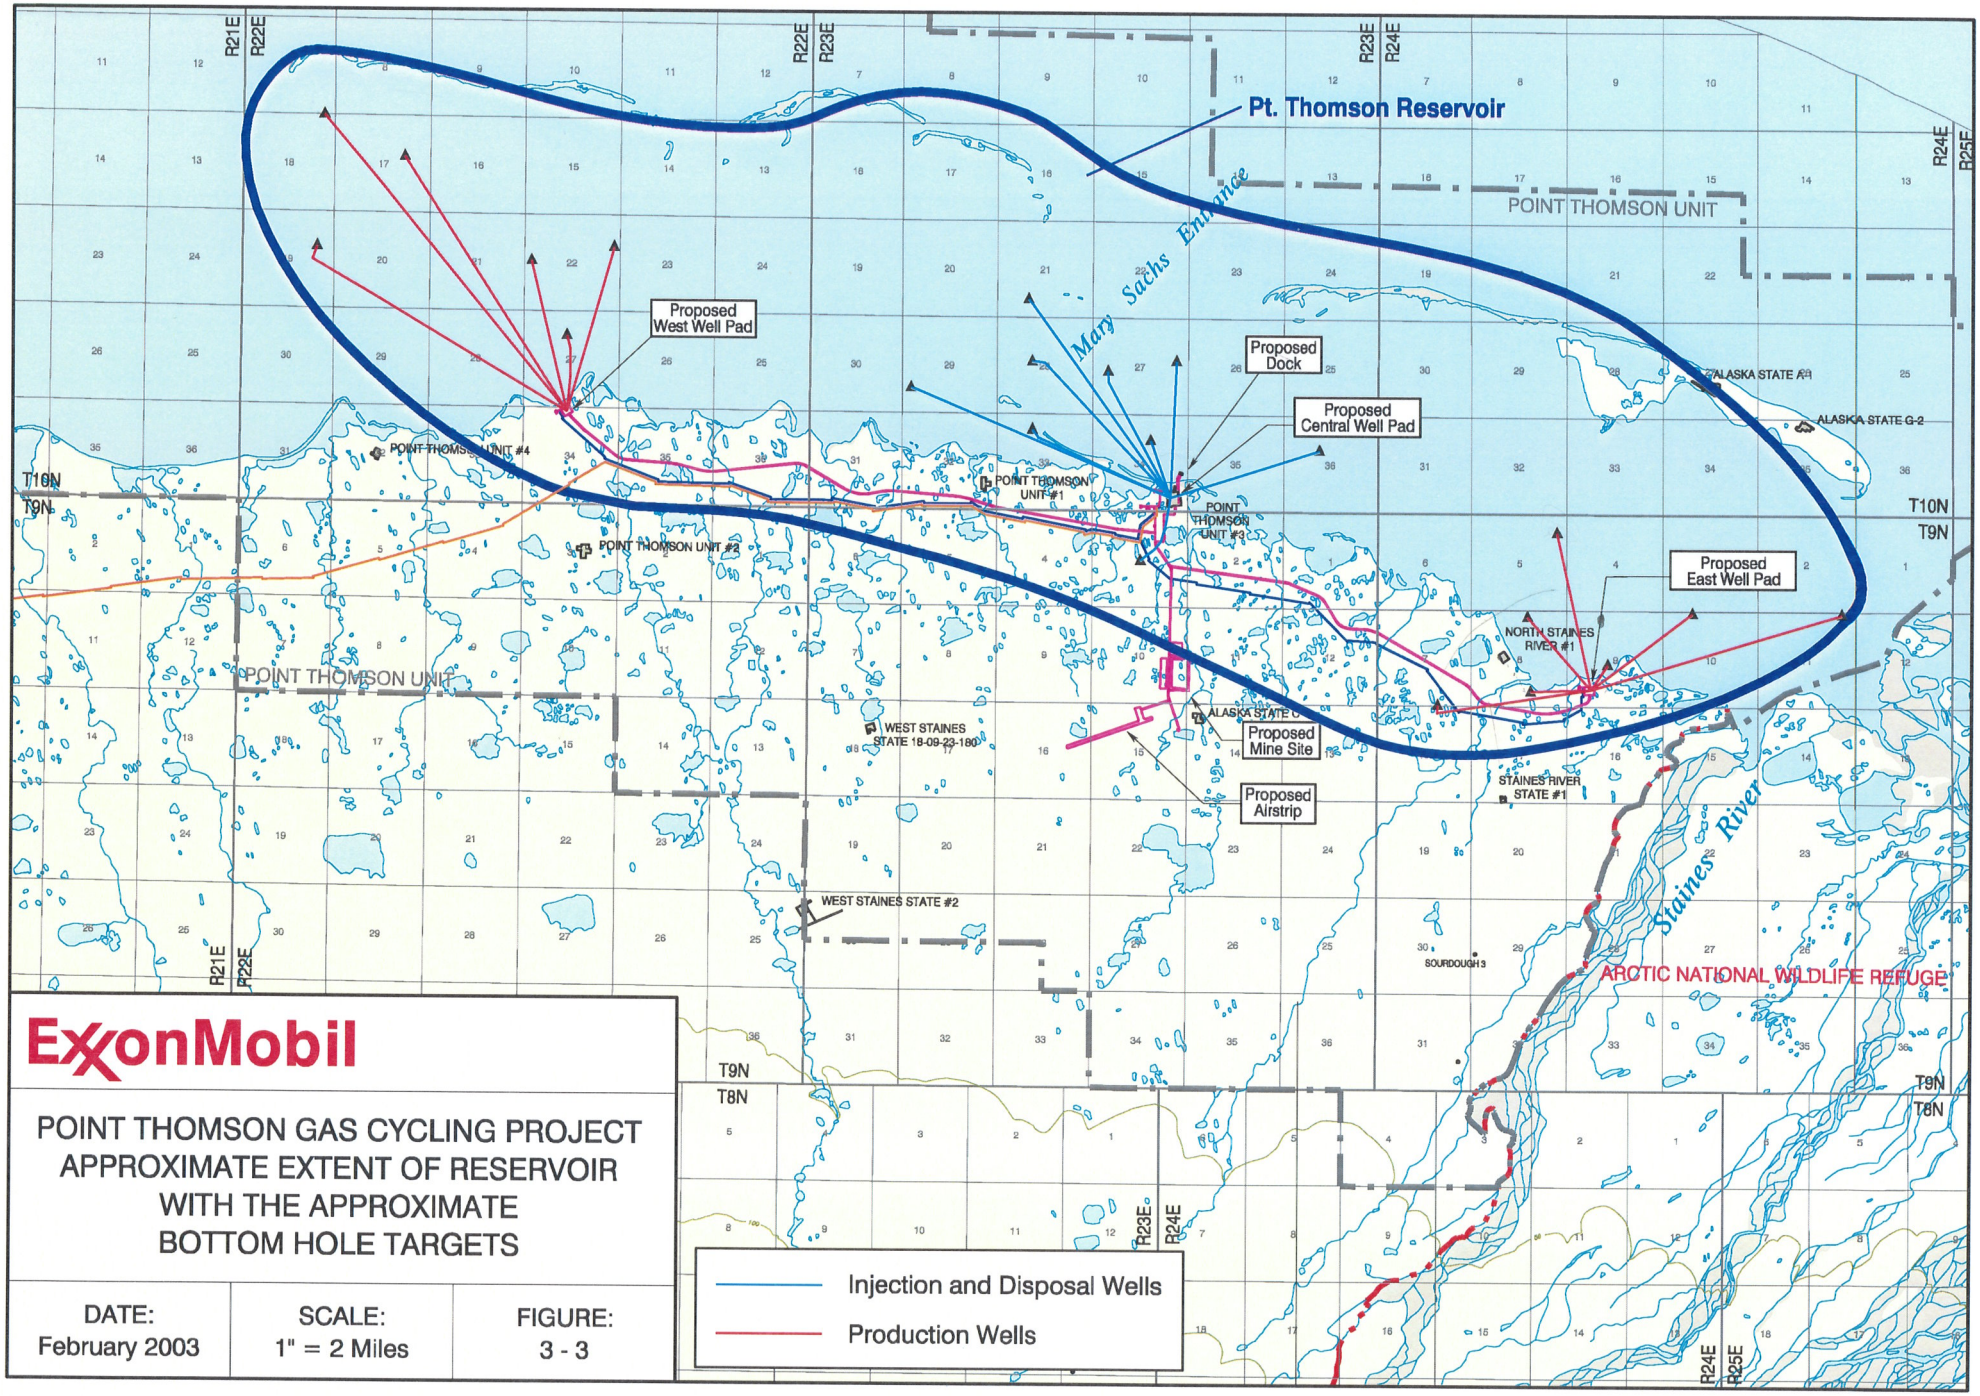
2) The maximum reach possible for attaining this/these target(s) considering existing drilling technology, geology and reservoir characteristics?

The Point Thomson reservoir is located approximately 12,700 feet below sea level with a reservoir pressure of about 10,000 psi and reservoir temperature of about 250° Fahrenheit. Drilling the Point Thomson reservoir will require the use of drilling mud with a static weight of approximately 15 – 16 pounds per gallon (ppg). The drilling mud must be heavy enough to hold back the reservoir pressure, but not so heavy that it overcomes the strength and breaks down the rock formation being drilled. In addition to the static mud weight, the equivalent circulating density (ECD) of the mud must also be considered. The ECD is the increased effective density exerted by the circulating fluid (drilling mud) against the formation due to the pump pressure needed to overcome friction in the annulus of the well as the mud is being pumped. This is important, as the difference between the ECD pressure and the formation strength represents the safe drilling window in which the pressure exerted by the drilling mud is sufficient to control the reservoir pressure, but not break down (fracture) the rock formation.

Increasing the horizontal departure (increasing the angle) of a well means a longer wellbore is drilled to reach the target depth of the formation. A longer well increases the amount of drilling mud circulating in the wellbore, increasing the friction and ECD of the mud and decreasing or removing the ability to safely drill the formation.

Another issue in drilling with high mud weights is known as “barite sag”. The mineral barite is commonly used to increase the weight of conventional water or oil based drilling mud. Under static (non-circulating) conditions such as when tripping drill pipe out of the wellbore, the barite can begin to settle within the mud column. This can result in heavier mud weight, above the formation fracture gradient at the bottom of the column, or a lighter mud weight higher in the column insufficient to hold back fluids or gas from the formation.

A literature search for examples of high departure wells successfully drilled in high pressure reservoirs yielded numerous documented cases from high pressure, high temperature (HPHT) gas fields in the North Sea. The three examples cited are the Kristin Field (SPE 95478, 2005), the Franklin and West Franklin Fields (SPE/IADC 119567, 2009) and the Kvitebjorn Field (SPE 105733, 2009). Reservoir pressure in these three fields ranged from 11,700 psi to 16,000 psi. The depth of the different reservoirs varied from approximately 13,000 to 17,400 feet subsea. The required drilling mud weight to drill these reservoirs ranged from 16.8 to 17.9 ppg. Horizontal departure for the wells drilled range from approximately 11,000 to 13,000 feet from the sea bed.



In order to decrease the occurrence of barite sag, two of the fields (Kristin and Kvitebjorn) employed cesium formate brines as the drilling fluid instead of a more conventional drilling mud weighted with barite. In the examples from the Franklin and West Franklin Fields micronized barite was used to achieve the required mud weight. The particle size of the barite was decreased until it could be held in colloidal suspension within a more conventional oil based mud.

Although these examples are not exactly analogous to the Point Thomson reservoir in that they are all significantly higher pressure and the reservoirs are located deeper below the ground surface, they do demonstrate current limits of drilling departures in high pressure fields. By using more exotic drilling fluids, the reservoir pressure at which drill high departure wells can be successfully drilled has increased, but the horizontal departure of the wells is still within the range of 10,000 to 13,000 feet proposed by Exxon for this project. The drilling departures achieved in the North Sea examples were also in wells drilled to deeper target depths than the Point Thomson reservoir. The deeper target depths allow for a greater departure because a lower wellbore angle needed to achieve that departure.

Based upon the examples given above, the drilling departures proposed by Exxon for this project appear achievable, but near the limits of those drilled in high pressure reservoirs elsewhere. The ability to drill longer departure wells at Point Thomson may increase in the future as experience is gained by drilling the initial wells and with continued advances in drilling technology.

POINT THOMSON PROJECT EIS

Memo

To:	Julie McKim, Corps of Engineers		
From:	Michael Allwright, HDR Alaska	Project:	Point Thomson Project EIS
CC:		Subject:	RFI#64 – Locational constraints
Date:	May 4, 2010	Job No:	123515

Purpose

HDR was asked to describe the constraints of separating the gas reinjection compression facility from the Central Pad well head location. This information request was to assist in developing a discussion of alternatives within the Environmental Impact Statement. This is, of necessity, a high level evaluation, as details of existing conditions and possible consequences could exist of which the HDR engineering team that prepared this memo is unaware.

Concept Description

The as-proposed design consolidates all Central Pad drilling, processing, compression, construction lay down, warehouse, maintenance and permanent and construction camp facilities at the expanded existing Central Pad (see Point Thomson Project Description Figure 5.3). The alternative concept involves relocating all facilities except drilling from the Central Pad to the mine location. The goal of this concept is to avoid expansion of the Central Pad near the shoreline, with the associated shoreline impacts. In addition to the relocation of the Central Processing Facility (CPF) and compressors, the gathering lines are rerouted along the proposed roads from the East Pad to the mine and the West Pad to the mine.

This concept consolidates all functions at a new location. The possibility of separating central processing facilities from gas compression facilities was not considered to be a viable option, as these functions are closely integrated in the multi-step condensate separation process (see Point Thomson Project Description Figure 5.4). In addition, the need to staff both the CPF and the compression equipment would require that both be adjacent to the Camp.

Assumptions

Existing pipeline distances between the various locations are identified to calculate the incremental piping required under the concept alternative. Line size is identified for purpose of estimating the incremental cost of pipe and installation, although we have not conducted this cost calculation. Also included in Table 1 are injection gas parameters and piping assumptions.

Assumptions		
Distances - Proposed		
East Pad to Central Pad as proposed	miles	5.00
West Pad to Central Pad as proposed	miles	4.75
Distances - Relocated		
Central Pad to Mine by road	miles	2.00
East Pad to Mine by road	miles	4.25
West Pad to Mine by road	miles	5.75
Line Sizing		
Gathering Line	inch	8
Gathering Line, Future	inch	18
Export Line (CRA)	inch	12
Disposal Line (new)	inch	6
Injection Line (new)	inch	Calc'd
Gas Injection Pipeline		
P1, Compressor Discharge Pressure	psia	10000
P2, Wellhead Pressure	psia	Calc'd
L, Length of Pipeline Mine to Cpad	miles	2.00
Specific Gravity (air=1)		0.70
T, Temperature Flowing Gas	^{o}F	100
Z, Compressibility		0.998
F, Safety Factor		0.72
S, Tensile Strength of Pipe	psi	75000
D, Diameter Outside (nominal)	inches	Selected
Di, Diameter Inside	inches	Calc'd
t, Thickness of Pipe Wall	inches	Calc'd

Table 1 - Assumptions

Note that the gathering pipeline would be shorter by .75 miles from the East Pad to the Mine Pad, and the gathering pipeline would be longer by 1 mile from the West Pad to the Mine Pad. The export pipeline will also be 1 mile longer, as it follows the same route as the West Pad gathering pipeline.

Discussion of Injection Pipeline Size

The reinjection gas pipeline is assumed to operate at a pressure identical to the compressor discharge pressure, or 10,000 psia maximum allowable operating pressure (MAOP). Selecting the size of the injection line is complicated by the possible expansion of gas production beyond the proposed initial 200 MMscfd. If a pipeline sized to transport 200 MMscfd is selected, it may be unable to transport 1,000 MMscfd without incurring significant pressure drop between the compressor and the wellhead. If volume increased beyond 1,000 MMcfd, pressure drop could be so large as to reduce well head pressure below what is required for injection. However, a second line, similar to the concept proposed for “future” gathering pipelines, could be considered to increase injection gas pipeline capacity, should that be necessary. Alternatively, a larger pipeline could be selected initially that would be capable of transporting the expected ultimate production capacity. However, this would come at significantly greater initial cost.

Table 2 below illustrates the relationship between pipe size, gas flow, and the resulting pressure drop over the 2 miles between the assumed compressor location and the Central Pad wellhead. Pressure drop is proportional to the length of the pipeline, so pressure drop for any alternative distance can easily be calculated.

Nominal Diameter inches	Outside Diameter inches	Wall t @ 10,000 psia	Inside Diameter inches	Pressure Drop (psi) in 2 Miles at Q Flow				
				200 MMcfd	400 MMcfd	600 MMcfd	800 MMcfd	1,000 MMcfd
12	12.75	1.11	10.53	26.1	104.8	237.3	426.0	674.2
16	16	1.48	13.04	8.3	33.4	75.3	134.2	210.5
20	20	1.85	16.30	2.5	10.1	22.8	40.6	63.6
24	24	2.22	19.56	1.0	3.8	8.6	15.3	24.0

Table 2 – Pressure Drop vs. Pipe Size and Gas Volume

Table 2 also begins the calculation with 10,000 psia compressor discharge, resulting in a wellhead pressure less than 10,000 psia. This assumes that the post-pressure drop wellhead pressure is sufficient for gas injection. If 10,000 psia must be maintained at the wellhead, the compressor must discharge at a greater pressure, and the wall thickness on the injection line must increase accordingly.

For any given pipe size and flow, the pressure drop must be provided by an increase in final stage compressor horsepower. This increase in work will require an increase in fuel consumption and associated emissions. Obviously, the smaller the pressure drop the less additional work is required, and the less fuel is required. Table 3 estimates the percent increase in horsepower required for each pipe size and flow rate condition.

Nominal Diameter inches	Percent Increase in Horsepower Requirements at Q Flow				
	200 MMcfd	400 MMcfd	600 MMcfd	800 MMcfd	1,000 MMcfd
12	0.20%	0.80%	1.79%	3.19%	4.98%
16	0.06%	0.25%	0.57%	1.02%	1.59%
20	0.02%	0.08%	0.17%	0.31%	0.48%
24	0.01%	0.03%	0.07%	0.12%	0.18%

Table 3 – Pressure Drop vs. Pipe Size and Gas Volume

The increase in horsepower is assumed to be directly proportional to an increase in fuel and emissions. Table 4 below estimates the increased annual fuel required based on 15 MW and 10,000 Btu/kWh heat rate.

Nominal Diameter inches	Estimated Annual Increase in Fuel (MMcf) at Q Flow				
	200 MMcfd	400 MMcfd	600 MMcfd	800 MMcfd	1,000 MMcfd
12	2.9	11.6	26.2	46.5	72.8
16	0.9	3.7	8.4	14.9	23.2
20	0.3	1.1	2.5	4.5	7.1
24	0.1	0.4	1.0	1.7	2.7

Table 4 – Estimated Increase in Annual Fuel Use

Discussion of Advantages and Disadvantages

Advantages of Moving CPF to Mine Location:

1. Perceived environmental benefits associated with increased distance from the shoreline due to reduced activity, light, and noise.
2. There would be no need to expand the existing Central Pad.
3. The gathering/export/disposal/injection pipelines would be co-located with the proposed roads. This would reduce the quantity of linear corridor disturbed by infrastructure. This may result in reduced construction costs initially, and possibly reduced O&M costs over time, since ice road access would not have to be built.
4. There would be no need to haul a significant quantity of gravel from the mine to the Central Pad. Although approximately the same quantity of gravel would be mined to build the Mine Pad, it would be placed adjacent to the mine and the transport would be largely eliminated.
5. Locating the camp adjacent to the airfield may be beneficial.

Disadvantages of Moving CPF to Mine Location:

1. There will be an increase in pipeline length and associated cost. Based on the distances noted on Assumptions Table 1, the following pipeline changes would be required:
    a. 12” Export pipeline increases by 1.0 mile.
    b. 8” Gathering pipelines (total) increase by 2.25 miles. Included in this is 2 miles of new gathering pipeline from the Central Pad to the Mine Pad to transport Central Pad production.
    c. 18” Future Gathering pipeline increases by .25 miles. Not included in this is any expansion of gathering pipeline from the Central Pad, assuming that most wells will be drilled from East and West Pads. If additional wells are drilled at Central Pad, 18” Future Gathering pipeline would increase by 2.25 miles.
    d. 12” to 20” Injection pipelines (new - line size unknown) is 2 miles long. Due to the extremely thick wall of large diameter pipe and difficulty in field welding, multiple smaller diameter pipes would likely be selected.
    e. 6” Disposal pipeline (new - line size assumed) is 2 miles long. Alternatively, the disposal well could be drilled from the Mine Pad location adjacent to the CPF, unless it is already installed at the Central Pad.
2. There will be a 1 mile increase in the need for VSMs. This assumes that whenever possible, all co-located pipelines will be installed on a single VSM alignment. This will make for a congested VSM between the Mine Pad and the Central Pad, as it would support the following pipelines: assumed multiple 12” to 20” injection, unknown future injection, 8” West gathering, 18” future West gathering, 8” Central gathering, 12” export, 6” disposal, communications and power. Expansion of Central Pad production may also require addition of a future Central Pad gathering pipeline.
3. The stored potential energy in 2 miles of injection pipeline(s) is significant, and increases the safety risk associated with a pipeline failure. Safety relief systems would also have to be evaluated for capacity.
4. The additional pipeline length will add cost and increase schedule. These impacts have not been evaluated.

5. Large and heavy loads transported by barge and landed at the bulkhead will need to travel an additional 2 miles to the Mine Pad. This will increase the load capacity and possibly width requirements on the Mine Road.
6. The pressure drop in the injection line will require an increase in compressor fuel consumption which will become more significant as production volume increases.
7. The increased export line length will increase power required for pumping condensate.
8. The increased disposal pipeline will increase power required for pumping waste water to the disposal well.
9. The increased fuel consumption for compression and electric power will increase air emissions.
10. Selecting an injection pipeline of sufficient size to support ultimate production capacity is inconsistent with current design to initially build for 200 MMcfd with capability to expand when production is proven. If this conservative philosophy is maintained, multiple small diameter injection pipelines will be required.
11. The relocation of the CPF from the shoreline at the Central Pad to the (proposed) Mine Pad location places the CPF one mile closer to ANWR. This would seem to be inconsistent with one of the original objectives, i.e. to increase separation of people, noise and light from ANWR.
12. Relocation may require movement of the existing worker's camp from Central Pad to Mine Pad.

There may be other considerations of which the HDR engineering team is unaware. The tradeoffs listed above identify, at a very high level, the consequence of moving the CPF to an alternate location. This analysis has not considered whether the proposed mine location is "far enough" to satisfy the original intent of the relocation, or is even in the right direction. However, the proposed mine location was determined to be a reasonable location for this analysis, so as to avoid even more road and pad construction if a CPF location were selected further south or west.

Memo

To:	Michael Allwright, HDR Anchorage
From:	David Sporer, HDR Engineering, Ann Arbor
Project:	Point Thomson EIS — Project No: 123515
Date:	27 September 2010
Subject:	Separated Compressor Station Alternative Concept Discussion – RFI #64a

Purpose

HDR Engineering in Ann Arbor, Michigan, previously evaluated the concept of moving the Central Processing Facilities (CPF) and the gas compression facilities from the Central Pad to the Mine Pad. Memo RFI #64 provides this information. In that memo, we dismissed the concept of separating the CPF from gas compression as not viable. This memo further discusses this alternative concept, and identifies its likely impacts on facilities, safety, operations, and the environment.

Alternative Concept Description

The as-proposed base design consolidates all Central Pad drilling, processing, compression, construction lay down, warehouse, maintenance, and camp facilities at the expanded existing Central Pad (see EIS Figure 5.3). An alternative concept involved separating and relocating the gas compression facilities to an alternate unspecified location. The goal of this concept is to increase the separation of the noise generated by the gas compressors from the Arctic National Wildlife Refuge (ANWR). In addition to relocating the gas compressors, extended suction and discharge pipelines, and operations and maintenance support facilities are required under this alternate concept.

Discussion of Alternative Concept

In memo RFI #64, HDR stated that:

The possibility of separating central processing facilities from gas compression facilities was not considered a viable option, as these functions are closely integrated in the multi-step condensate separation process (see EIS Figure 5.4). In addition, the need to staff both the CPF and the compression equipment would require that both be adjacent to the Camp.

In addition to the previously identified disadvantages of moving both the CPF and compression to the Mine Pad location, discussed in RFI #64, additional consequences result from separating the CPF from the compression facilities, as follows:

1. Although environmental benefits may be associated with increased distance of compressors from ANWR due to reduced O&M activity and noise, this desired benefit may not be measurable.
    a. Gas turbines supply power to both the CPF and the compressors. Moving the compressors will also require either moving approximately 16 MW of gas turbine generation capacity, or extending power lines to the CPF. If power lines are not used, several gas turbines must remain at the Central Pad to supply the generation needs of the CPF and the associated worker's camp. In addition, diesel generation supports the power requirements of the drill rig.
    b. Reciprocating compressor noise is largely contained within its housing module, and is not likely to be the dominant source of "far-field" noise measured at the Central Pad boundary. The gas turbine inlet and exhaust noise and drill rig diesel exhaust noise will likely dictate the far-field low and high frequency noise at the Central Pad boundary.

Ann Arbor, MI 48108-8949
Phone (734) 761-9130
Fax (734) 761-9881
www.hdrinc.com

   c. Noise (A-scale decibels) cannot be arithmetically added. For example, when two noise sources collectively produce 100 dB, shutting down one of them may result in only a 3 dB noise reduction, with 97 dB noise remaining at the far-field receptor. Removing a similar noise source (i.e. the gas turbines used for power generation) from the Central Pad is equivalent to shutting down those sources at the Central Pad. Therefore, the remaining far-field high frequency noise at Central Pad may be barely diminished.
   d. Far-field high frequency noise attenuation is a logarithmic function based on distance ratio from the noise source. Assume we measure noise at the east edge of the Central Pad, 800 feet from the noise source. Noise measured at double this distance (i.e.1600 feet) is reduced by 6 dB. Similarly, at 8000 feet, or 10 times the distance, noise is reduced by 20 dB.
   e. Separating high frequency noise sources will likely increase the far-field area over which noise can be heard. Concentrating noise at one location can minimize the noise “footprint”, and simplify attenuation design.
   f. Gas flowing through a pipeline also generates noise, especially at valves and fittings. While not at a frequency associated with power generation, many miles of pipeline may distribute high frequency noise over a wider area.
2. Separating the CPF from compression facilities will require an increase in the injection pipeline length and associated cost. The injection pipeline requires 10,000 psi gas pressure available at the wellhead, and is the most significant pipeline addition. As previously discussed, volume assumptions will determine pipeline sizing requirements. This is very thick wall pipe, which is expensive to fabricate, transport, and weld in the field. Depending on the assumed separation distance, pressure drop in the injection pipeline(s) becomes a significant issue. If production capacity is increased, expansion of this pipeline system will be very expensive.
3. Under the alternative concept, the other major pipeline addition is the compressor suction pipeline from the CPF to the compressors, which will operate at 2,700 psi and require thick wall piping.
4. Additional VSMs are required between the facilities to carry the injection pipeline(s), suction pipeline, possible disposal pipeline, possible condensate return pipeline, communications, and other systems not yet defined.
5. As pressure drop in the injection pipeline increases, the power required for compression increases. Air emissions increase in direct proportion to power generated.
6. In EIS Figure 5.4, there appears to be condensate produced from the compressor inter-stage cooler returned to the CPF process. There may be other interconnects between the compressors and the CPF of which we are unaware. These potential interconnects will require additional piping between the separated compressor location and the CPF.
7. Moving the compressors west rather than south would meet the objective of increasing the distance to ANWR. The effect of this move will be the addition of a new road capable of supporting the weight of compressor modules landed by sealift at Central Pad. Bridges and gravel quantities will increase.
8. Separation of compressors from the CPF will require a significant duplication of infrastructure. Depending on the distance involved, the following issues need to be considered:
   a. As previously noted, gas turbine power generation will either be required at each location or a new transmission line installed between. Total reserve capacity for both locations will be larger than the reserve required if power is concentrated at a single location.
   b. Personnel camps are likely at both locations, unless the distance is close enough to allow daily travel.
   c. Location of airport will be at greater distance from either CPF or compressor facility than the current consolidated arrangement. Re-supply will therefore require more road traffic.
   d. More road miles require more maintenance.
   e. More total personnel may be required as special skills are needed at both locations.
   f. More road and people equals more vehicle miles, which increases emissions and safety concerns.

   g. A second disposal well may be required unless the project installs a disposal pipeline between facilities. This pipeline may be intermittently used, and subject to freezing. This would require freeze protection on this system.
   h. Duplicate facilities are likely required to service each location, including maintenance shop, warehouse, flare, relief valve, fuel tanks, safety zone, and mobile equipment.
9. The stored potential energy in unknown miles of injection and compressor suction pipelines is significant, and increases the safety risk associated with a pipeline failure. The project must also include significant safety relief systems if the alternate concept were adopted.
10. More gas will vent to flare and atmosphere in the event of an emergency shutdown.
11. Air emissions will be greater due to increased power generation required to overcome pressure drop in the injection pipeline. In addition, increased vehicle miles add to net emissions.
12. Additional complexity will add to cost and schedule. We did not evaluate this impact in detail.

Other negative aspects of the alternative concept include additional operating resources at a second facility; increased O&M activity on interconnecting equipment; increased lighting; increased travel issues; interconnecting utility issues; reduced personnel safety; communication difficulties; and an increase in environmental impact. There are no obvious benefits offered by the alternative concept, aside from potentially lower low frequency noise emissions at closer proximity to the ANWR, and a slightly reduced Central Pad size.

The tradeoffs listed above identify, at a very high level, some of the consequences of separating the compressor facility from the CPF under the alternate concept. This analysis has not considered the impact on operational reliability, schedule, logistics, cost, or other factors of which we are unaware. However, HDR suggests that the alternative concept offers no significant benefits to facilities, safety, operations, or the environment.

Memo

To:	Michael Allwright, HDR Anchorage
From:	David Sporer, HDR Engineering, Ann Arbor
Project:	Point Thomson EIS — Project No: 123515
Date:	27 September 2010
Subject:	Relocate Point Thomson to Badami Alternative Concept Discussion – RFI #64b

Purpose

HDR Engineering in Ann Arbor, Michigan, previously evaluated the concept of relocating the Central Processing Facilities (CPF) and the gas compression facilities away from the Lion Bay shoreline. Memo RFI #64 provides this information. In that memo, we evaluated the concept of moving the CPF and gas compression facility from the wellhead to the Mine Pad location, two miles south of Central Pad. This memo evaluates the concept of moving the CPF, compressors and camp from the Point Thomson Central Pad to Badami, 20 miles to the west, and identifies the likely affect on facilities required, safety, operations, and the environment.

Alternative Concept Description

The as-proposed base design consolidates all Central Pad drilling, processing, compression, construction lay down, warehouse, maintenance, and camp facilities at the expanded Central Pad (see EIS Figure 5.3). This alternative concept involves relocating all Point Thomson CPF and gas compression facilities to the Badami production pad, located 20 miles to the west of Central Pad. HDR understands that this concept will not include an interconnecting road between Badami and Point Thomson Central Pad, and the Point Thomson site will be unmanned. The goal of this alternative concept is to increase the separation of the noise generated by the facility from the Arctic National Wildlife Refuge (ANWR). In addition to relocating the gas compressors under this alternative, extended production and injection pipelines will be required.

Discussion of Alternative Concept

This concept is similar to the separated compressor concept discussed in RFI #64a. However, in this concept the remote equipment (CPF, compressors, and all support facilities) is located 20 miles from the production wells. This concept transports gas and condensate from the Point Thomson field to Badami at 2,700 psig, and returns injection gas to Point Thomson at a delivered pressure of 10,000 psig.

The drill rig, drilling support systems, drilling fluid, warehouse, fuel tanks, tubulars, consumables, tools and supplies will remain at Point Thomson until completion of the drilling program. The drill rig will move from the Central Pad to East and West Pads as required. We do not know the duration of the drilling program, or the disposition of the rig upon completion.

HDR understands that the existing infrastructure at Badami is insufficient to support the requirements of the Point Thomson equipment without significant improvement. The existing sealift bulkhead is unable to offload the planned Point Thomson modules, so the project must improve the bulkhead or redesign the modules. We do not know whether gravel is available to expand the Badami Pad, or whether water sources are sufficient to support the increased demand. HDR's Memo RFI #73 investigated the existing electric capacity of Badami and determined that Badami could not support the power needs of Point Thomson. In addition, the "excess" capacity at Badami served as backup capacity for the Badami power requirements, and could not be dedicated to Point Thomson base load requirements.

Phone (734) 761-9130
Fax (734) 761-9881
www.hdrinc.com

The long-term production infrastructure remaining at Point Thomson thus consists of:

- East, West, and Central Pads
- In-field road system
- Mine Pad
- Airfield
- Production wellheads
- Injection wellheads
- Gathering pipelines on VSMs
- Warehouse, maintenance shop, vehicle storage
- Transport vehicles
- Road maintenance equipment
- Emergency shelter
- Emergency power generation
- Production export pipeline(s), injection pipeline(s), electric power transmission line, fiber optic communication cable, future pipeline capacity, and other systems installed on one or more sets of VSMs (from Point Thomson to Badami).

HDR previously identified in RFI #64 the disadvantages of moving the CPF, compressors, and camp 2-miles south to the Mine Pad location. Additional consequences result from moving these facilities 20-miles west from the wellheads without a permanent access road, as follows:

1. Gas turbine and compressor noise will move to a greater distance from ANWR. If Point Thomson noise could be measured at ANWR, this may have some environmental benefit. However, sufficient local mitigation of noise will eliminate this benefit.
2. The base case (as-proposed) export pipeline is eliminated, although replaced with multiple production and injection pipelines. The base case export pipeline is a liquids line operating at a pressure significantly below that required in both the production transport pipelines and the gas injection pipelines.
3. Expansion of the Central Pad is not necessary. However, expansion of Badami by a similar amount is likely.
4. We assume Point Thomson will reduce the 6,500 psi production pressure at the wellhead to maintain 2,700 psig at the inlet to the CPF. Separating the wells from the CPF requires a 20-mile three-phase production export pipeline. Initial plans used an 8” pipeline for a single production well. The concept design could consider combining these flows into a larger line starting at the West Pad. This production pipeline will operate above 2,700 psig due to pressure drop, and will contain water, condensate and gas. The presence of CO_2 at high pressure requires special metallurgy to prevent corrosion. The high operating pressure and special metallurgy requires thick wall pipe and special welding procedures. Even the base case volume of 200 MMscfd is likely to require multiple pipelines. Normal flowing temperature is 180 ^{o}F, with estimated hydrate formation at 80 ^{o}F at flowing pressure. Insulation of these pipes is required to prevent temperature loss and hydrate formation during normal operation. Hydrate formation is a significant concern if the line is out of service for any length of time.
5. To maintain gas cycling under this alternative concept requires a 20-mile injection pipeline from the compressor to the injection well. The injection pipeline requires 10,000 psig gas pressure available at the wellhead. As previously discussed, volume assumptions will determine pipeline sizing requirements. Pressure drop in the injection pipeline(s) becomes a significant issue at this distance. At 200 MMscfd injection rate, HDR estimates installation of three 12-inch pipes will result in a pressure drop of about 30 psi. However, expanding volume to 300 MMscfd will increase pressure drop to over 65 psi. Expanding volume to 400 MMscfd will increase pressure drop to about 120 psi. These flows and pressure characteristics requires very thick wall pipe, which is expensive to fabricate, transport, and weld in the field. If production volume is increased, expansion of this pipeline system will be very expensive.
6. Reservoir performance may require higher pressure to maintain injection volume. Conservative pipeline design must consider this possibility, resulting in 20 miles of injection pipeline installed at a maximum

allowable operating pressure well above 10,000 psi. This compares to several hundred feet of injection pipeline where the compressor is adjacent to the injection well.

7. Additional VSMs are required between Badami and Point Thomson to carry the injection pipeline(s), suction pipeline(s), communications, and other systems not yet defined.
8. As pressure drop in the injection pipeline increases, the power required for compression increases. Air emissions increase in direct proportion to power generated.
9. Moving CPF, compressors and camp to Badami will require some duplication of infrastructure. Operations and maintenance of the wellheads requires consideration of the following:
    a. Daily inspection of the wellheads is prudent. This will require daily work force transport via airplane or helicopter, with support vehicles and maintenance equipment present at Point Thomson.
    b. If weather conditions prevent departure from Point Thomson, sufficient camp facilities are necessary for an extended stay.
    c. Interruption of electric transmission from Badami to Point Thomson may require that Point Thomson provide emergency power capacity, with associated emissions and noise.
    d. Road and runway maintenance equipment must be available at the airport. Impassable roads may delay access to wellheads.
    e. Some duplicate facilities are likely required at Point Thomson, including maintenance shop, warehouse, fuel tanks, safety zone, and mobile equipment. This alternative concept must also evaluate the need for a duplicate flare system.
10. In the event of a well failure, emergency response under this alternative will be 20 miles away without road access. If weather conditions preclude air transport, a significant delay of emergency response will occur.
11. The stored potential energy in 20-miles of production and injection pipelines is very significant, and increases the safety risk associated with a pipeline failure. The project must also include significant safety relief systems.
12. More gas will vent to flare and atmosphere in the event of an emergency shutdown.
13. Air emissions will be greater due to increased power generation required to overcome pressure drop in the injection pipeline. Air transport for daily well inspections also increases noise and emissions local to ANWR.
14. Additional complexity will add to cost and schedule. We did not evaluate this impact in detail.

Other negative aspects of the alternative concept include increased O&M activity on interconnecting equipment, increased travel issues, interconnecting utility issues, reduced personnel safety, communication difficulties, and an increase in environmental impact. There are no obvious benefits offered by the alternative concept, aside from potentially lower low frequency noise emissions at closer proximity to the ANWR, and somewhat smaller Central Pad size.

We estimate that the life cycle cost to relocate the CPF, compressor and camp to Badami is significant, while additional costs to attenuate noise at the Central Pad are judged comparatively insignificant. HDR suggests that the alternative concept offers no significant benefits to facilities, safety, operations, or the environment.

The tradeoffs listed above identify, at a very high level, some of the consequences of moving CPF, compressors and camp to Badami. This analysis has not considered the ability of the Badami site to expand sufficiently to install the required equipment, nor whether the dock is capable of receiving the contemplated modules. This analysis has not considered the impact on operational reliability, schedule, logistics, cost, or other factors of which we are unaware.

POINT THOMSON PROJECT EIS

Memo

To:	Julie McKim, Corps of Engineers		
From:	Michael Allwright, HDR Alaska	Project:	Point Thomson Project EIS
CC:		Subject:	RFI#65 – Compressor Comparison
Date:	May 17, 2010	Job No:	123515

Purpose

HDR was asked to evaluate the characteristics of reciprocating and centrifugal compressors in application to the Point Thomson compression requirements. This information request is to assist in developing a discussion of alternatives within the Environmental Impact Statement. This is, of necessity, a high level evaluation, because details of existing conditions and possible consequences could exist of which HDR is unaware.

Concept Description

The as-proposed process flow is represented on EIS Figure 5.4. Compression will be required to re-inject dry gas back to the formation in order to maintain field pressure necessary to maximize production of condensate. Production at approximately 6500 psig is transported to the Central Production Facility located at the Central Pad. Separation of condensate from natural gas is accomplished through pressure reduction and cooling, with condensed liquids carried off the bottom of separator vessels and dry gas discharging from the top of vessels. Eventually, dry gas must be compressed from approximately 2700 psig to 10,000 psig in order to re-inject the gas into the field. As indicated to HDR (ExxonMobil response to RFI #66, dated 5/13/2010), it is proposed to use 4 x 25% capacity reciprocating compressor units to accomplish re-injection of 200 MMcfd. The following discussion reviews the characteristics of centrifugal and reciprocating compressors in application to this intended service.

Discussion of Compression Characteristics

Generally, centrifugal compressors are preferred over reciprocating in large volume applications. While centrifugals are slightly less efficient at low flows, and therefore require more horsepower, they typically require less maintenance than reciprocating due to the reduction in vibration. There is no clear point at which reciprocating compression is no longer technically or economically viable. The initial volume projection of 200 MMcfd is in this “gray” area; 200 MMcfd is small for a centrifugal, and large for the reciprocating. In any application there is a need for reliability and redundancy. While it is important to install equipment with a high degree of reliability (capacity factor), it is equally important to design the overall plant with attention to single component failure. For example, it is important to understand the impact on production if any one component is out of service for maintenance. The consequence of scheduled or corrective maintenance on a single compressor installation (1 x 100%) would be the complete shutdown of production, whereas the consequence of a maintenance outage on one unit of the proposed multi-unit installation would be a partial shutdown of production. At the initial volume rate of 200 MMcfd, a 1 x 100% centrifugal installation would shut down production for scheduled or corrective maintenance. The possible solution to this issue would be the installation of a spare compressor, resulting in a 2 x 100% installation.

Very few suppliers are capable of providing equipment capable of meeting the 10,000 psi discharge pressure requirement. Two suppliers of centrifugal and reciprocating compressors were able to respond to our request for information, Dresser Rand and GE Oil and Gas.

General Description

Dresser Rand provided preliminary information on both a centrifugal and a reciprocating compressor concept based on their compressor sizing program. The centrifugal design estimated a two-stage compressor gear coupled to a LM2500 gas turbine with 23,715 hp (17.7 MW) required. This would also be a 1 x 100% installation.

The Dresser Rand reciprocating compressor design was based on 4 x 25% compressors driven by electric motors. Total power required at the compressor was 17,224 hp, but due to electrical motor inefficiency and mechanical losses, continuous power generation was estimated to be 19,290 hp (14.4 MW). Inductance power requirements at startup of the electric motors would require an additional 1 MW of installed capacity. For comparison purposes, this design study ties the gas turbine power generator to the electric motor drives, but in practice the motors would be connected to the site power distribution grid. With the addition of the inductance power load, the installed capacity of the power block would need to be increased to 15.4 MW. This capacity addition would be consistent with the power equipment planned for the balance of the plant. HDR was informed that Solar Taurus 70 turbines (rated at 7.5 MW each) are proposed for power generation, and assumes that the electric motors will require the addition of two or three Taurus 70 turbines, depending on balance of plant loads.

Table 1 below summarizes some of the differences between the centrifugal and reciprocating compressors.

General Description	Centrifugal	Reciprocating
Compressor Configuration	1 x 100%	4 x 25%
Compressor arrangement	Compressor gear coupled to gas turbine	Compressor with direct electric motor drive
Compressor Stages / Cylinders	2 - Stage	2 - Stage
Drive type	Simple Cycle Gas Turbine	Electric Motor
Brake Horse Power at Compressor Shaft	~23,250 BHP	17,224 BHP
Efficiency Factor from Power Supply	1.02 (Mechanical losses in gear 2%)	1.12 (Electric Motor 10% loss, Mechanical losses 2%)
Total Continuous Power (BHP)	23,715 BHP	19,290 BHP
Total Continuous Power (MW)	**17.7 MW**	**14.4 MW**
Additional Startup Power Required	na	Inductance loading at start-up 25% of 1 compressor Oversize by 1 MW or supply from Power Grid
Required Gas Turbine Capacity	17.7 MW	15.4 MW

Table 1 – General Description of Centrifugal and Reciprocating Compressor Installations

GE Oil and Gas supplied information on a centrifugal installation; however, they do not offer a reciprocating compressor which meets application requirements. The preliminary information provided by GE Oil and Gas was not modeled with their compressor programs. The preliminary estimate was based on a PGT25 gas turbine (mechanical drive version of the LM2500) rated above the 20,000 bhp necessary to drive two compressors in series through a gear box. An intercooler would be required. The turbine would be upgraded for Dry Low Emissions (DLE) producing 25 ppm for both NOx and CO. This would be a 1 x 100% installation.

Compressor Characteristics and Comparison

Either compressor alternative is ultimately driven by a gas combustion turbine, with assumed emission rates of 25 ppm for both NOx and CO. A heat rate of 9,700 btu/kWh is typical for an LM2500, with the Taurus 70 slightly higher at 10,100 Btu/kWh. The emissions in tons per year (tpy) are a function of fuel consumed to

meet the load. Based on these assumptions the larger centrifugal load will result in greater emissions than the reciprocating alternative. Note that emissions are calculated based on assumed pipeline quality natural gas. Actual emissions will vary based on fuel gas quality.

Turndown is related to the ability to operate the equipment at less than full load. With the centrifugal compressor, the limit of turndown is approximately 70% of full load. Although the 5000 hp reciprocating compressor motor could be equipped with a variable frequency drive, the complexity, cost and additional footprint weigh against this option. Therefore, the turndown of the reciprocating compressor installation would be stepwise at 25% increments. Some additional flexibility is possible with variable pockets on each cylinder.

For either compressor type, interstage cooling will be required between stage 1 and stage 2. While there may be minor differences in lube oil and interstage cooling requirements, these are not expected to be significant.

The reliability assessment is qualitative rather than quantitative. Dresser Rand, responding with both centrifugal and reciprocating compressor information, indicated that the reliability of the centrifugal unit is expected to be higher than that of the reciprocating unit. This assessment is also reflected in the operating time between overhauls, which favors the centrifugal. The major wear components identified in Table 2 also indicate the many components of the reciprocal compressor that will require maintenance over time. However, the redundancy of the 4 x 25% reciprocating installation enables each unit to be removed from service to perform maintenance, with a loss of only 25% of production capacity.

Table 2 below summarizes some of the major characteristics associated with centrifugal and reciprocating compressors.

Compressor Comparison	Centrifugal	Reciprocating
Emissions rate (ppm)	25 ppm NOx, 25 ppm CO	25 ppm NOx, 25 ppm CO
Emissions rate (lb/mmBtu)	.1025 lb/mmBtu NOx, .0625 lb/mmBtu CO	.1025 lb/mmBtu NOx, .0625 lb/mmBtu CO
Fuel rate (mmBtu/hr)	172 mmBtu/hr	145 mmBtu/hr
Emissions (tpy)	77 tpy NOx, 47 tpy CO	65 tpy NOx, 40 tpy CO
CO2 Emissions (tpy)	100,016 tpy CO2	84,725 tpy CO2
Turndown	Continuous - 70% to 100%	Step - 25%, 50%, 75%, 100%
Cooling	Lube oil cooler, intercoolers, by-pass cooler	Lube oil cooler, interstage cooler & by-pass cooler
Reliability	High (No Spare)	Lower (Spares are Typical)
Continuous Operating Time Before Major Overhaul	2-3 Years	1-2 Year
Major Wear Components	Mechanical Seals, Bearing surfaces	Valves, Piston Rings, Rider rings, Cylinder Liners, Piston Rods, Rod Packing
Noise (inside module)	85 (dBA) High Frequency	100 (dBA) Low Frequency
Vibration and Pulsation	Minimal based on proper system design.	Caused by piston motion, heavy foundation and protection needed on discharge.

Table 2 – Compressor Characteristics and Comparison

Either compressor alternative will be contained in a module. The noise inside the module from the centrifugal is estimated at 85 dB(A) at predominately high frequency. The reciprocating noise inside the module is estimated at 100 dB(A) consisting of mostly low frequency. The high frequency noise is easier to attenuate than the low frequency noise. In either case, the measure of noise performance should be at the boundary of the site. HDR notes that the module wall noise transmission loss rating of 25 STC is a measure of noise reduction across a wide range of frequencies. Thus, module attenuation of high frequency noise will likely be greater than 25 dB, while hard-to-attenuate low frequency may be reduced by less than 25 dB. HDR has no information to assist in determining noise attenuation performance of the module wall.

Vibration and pulsation is a function of the compressor design, and is inherent in the reciprocating compressor. Typically, heavy foundations and carefully designed pulsation bottles can control vibration.

Compressor Footprint Required

A significant difference between the centrifugal and reciprocating compression plants is in the total footprint required. The centrifugal is a 1 x 100% mechanical drive unit that requires significantly less space than the 4 x 25% electric drive reciprocating installation. Table 3 summarizes the estimated footprint requirements of the two alternatives.

Footprint	Centrifugal	Reciprocating
Compressor + Driver	2 stage + LM2500 at 87' x 15'	2 stage + 5000 hp electric at 25' x 25' each x 4 units
	NA	10' between units for rod pull
	Electric Switchgear (module power)	Electric Switchgear (module power + 4 x 5000hp)
	Pipe rack for suction/discharge piping	Pipe rack for suction/discharge piping x 4
	Laydown space for maintenance	Laydown space for maintenance
	Control room	Control room
	TOTAL = 110' x 50' = 5,500 sqft	TOTAL = 160' x 75' = 12,000 sqft
Power Module (incremental)	NA	Taurus 70 (34' x 10') x 3 units
		Spacing + balance of plant
		TOTAL = 90' x 60' = 5,400 sqft
TOTAL Footprint Required	5,500 sqft	17,400 sqft

Table 3 – Estimated Footprint Required

The reciprocating compression plant will require more space to accommodate the 4 compressor/motor units, the header suction and discharge piping, and the switchgear for starting the large electric motors. It was assumed maintenance space and control space are similar for each alternative.

The reciprocating compression plant will also require the generation of incremental electric power. As seen in Table 3, the footprint of the incremental power module is nearly identical to the footprint of the centrifugal compression plant. HDR had initially assumed a similar LM2500 gas turbine/generator producing 20 MW to power the electric motors. The installation of the assumed 7500 kW Solar Taurus units provides needed reliability, especially if part of a larger power module required to satisfy the power needs of the balance of the site. In either power plant case, the footprint of the incremental power plant is approximately equal to the footprint of the 1 x 100% centrifugal compressor plant.

Capacity Expansion Discussion

The initial design case for injection volume is defined as 200 MMcfd. Recognizing the need for redundancy, the plan requirements may be more suited to multiple-unit reciprocating than to centrifugal compression. As volume increases, the advantage swings to centrifugal. Dresser Rand indicated that a 3 x 33% centrifugal compressor installation would likely be the recommended design if gas injection volume were to increase to 1,000 MMcfd rather than 200 MMcfd.

The design philosophy utilized by ExxonMobil is to build what is required for the 200 MMcfd case, and enable the expansion of production, gathering, processing and injection as production capacity is proven. Eventual expansion of the gas compression plant may ultimately favor larger volume centrifugal compressors. With the addition of new centrifugal compression, the reciprocating compressors can remain in service to provide backup capacity, or even base load compression as volume increases over time.

There may be other considerations of which we are unaware. The tradeoffs listed above identify, at a very high level, the characteristics of centrifugal and reciprocating compressors.

POINT THOMSON PROJECT EIS

Memo

To:	Hank Baij, Corps of Engineers		
From:	Michael Allwright, HDR Alaska	Project:	Point Thomson Project EIS
CC:		Subject:	RFI #65 Augmented – Compressor Comparison
Date: June 30, 2010		Job No:	123515

Purpose

HDR was asked to evaluate the characteristics of reciprocating and centrifugal compressors in application to the Point Thomson compression requirements. This information request is to assist in developing a discussion of alternatives within the Environmental Impact Statement. This is, of necessity, a high level evaluation, as details of existing conditions and possible consequences could exist of which HDR is unaware.

Concept Description

The as-proposed process flow is represented on EIS Figure 5.4. Compression will be required to re-inject dry gas back into the reservoir in order to maintain field pressure necessary to maximize production of condensate. Production at approximately 6500 psig is transported to the Central Production Facility located at the Central Pad. Separation of condensate from natural gas is accomplished through pressure reduction and cooling, with condensed liquids carried off the bottom of separator vessels and dry gas discharging from the top of vessels. Eventually, dry gas must be compressed from approximately 2700 psig to 10,000 psig in order to re-inject the gas into the field. As indicated to HDR, it is proposed to use 50 MMscfd capacity reciprocating compressor units in a 4 x 25% configuration to accomplish re-injection of 200 MMscfd back into the formation. The following discussion reviews the characteristics of centrifugal and reciprocating compressors in application to this base case volume of 200 MMscfd, as well as an increased alternative volume case of 450 MMscfd.

Discussion of Compression Characteristics

Generally, centrifugal compressors are preferred over reciprocating in large volume, steady state applications. Centrifugals are less efficient than reciprocating, especially at low flows, and therefore require more horsepower. However, centrifugals typically require less maintenance than reciprocating due to the reduction in vibration. There is no clear point at which reciprocating compression is no longer technically or economically viable. The initial volume projection of 200 MMscfd is in this “gray” area; 200 MMscfd is very small for a centrifugal, and large for the reciprocating. In addition, a centrifugal operating at such low volume is much less efficient than at higher volumes.

On the other hand, the alternative volume case of 450 MMscfd can be easily handled by a single centrifugal compressor. Multiple reciprocating compressors would be required to accomplish the same work.

In any application there is a need for reliability and redundancy. While it is important to install equipment with a high degree of reliability (capacity factor), it is equally important to design the overall plant with attention to single component failure. For example, it is important to understand the impact on production if any one component is out of service for maintenance. The consequence of scheduled or corrective maintenance on a single compressor installation (1 x 100%) would be the complete shutdown of production, whereas the consequence of a maintenance outage on one unit of the proposed multi-unit reciprocating installation would be a partial shutdown of production. At the base case volume rate of 200 MMscfd, a 1 x 100% centrifugal installation would completely shut down production for scheduled or corrective maintenance on either the compressor or its' turbine driver. The possible solution to this issue would be the installation of a spare compressor, resulting in a 2 x 100% installation, or the ready availability of spare compressor and turbine internals to expedite repairs.

Very few suppliers are capable of providing equipment capable of meeting the 10,000 psi discharge pressure requirement. Two suppliers of centrifugal and reciprocating compressors were able to respond to our request for information.

General Description – Base Volume 200 MMscfd

Dresser Rand provided preliminary information on both a centrifugal and a reciprocating compressor concept based on their compressor sizing program. The centrifugal design estimated a two-casing compressor gear coupled in series to an LM2500 gas turbine with 23,715 hp (17.7 MW) required. HDR has conducted the following analysis based on a PGT25 gas turbine, the updated mechanical drive version of the LM2500. This would be a 200 MMscfd unit in a 1 x 100% configuration.

The Dresser Rand reciprocating compressor design was based on four 50 MMscfd compressors driven by 5000 hp electric motors in a 4 x 25% configuration. Total power required at the compressor was 17,224 hp, but due to electrical motor inefficiency and mechanical losses, continuous power generation was estimated to be 19,290 hp (14.4 MW). Inductance power requirements at startup of the electric motors would require an additional 1 MW of installed capacity. For comparison purposes, this design study ties the gas turbine power generator to the electric motor drives, but in practice the motors would be connected to the site power distribution grid. With the addition of the inductance power load, the installed capacity of the site power block would need to be increased by 15.4 MW over non-compression balance of plant load. HDR was informed that Solar Taurus 70 turbines (rated at 7.5 MW each) are proposed for power generation, and assumes that the electric motors will require two or three additional Taurus 70 turbines, depending on balance of plant loads.

GE Oil and Gas supplied information on a centrifugal installation; however, they do not offer a reciprocating compressor which meets application requirements. Although the preliminary information provided by GE Oil and Gas was not modeled with their compressor programs, the preliminary estimate was based on a PGT25 gas turbine (mechanical drive version of the LM2500) rated above the 20,000 bhp necessary to drive two compressors in series through a gear box. An intercooler would be required. The turbine would be upgraded for Dry Low Emissions (DLE) producing 25 ppm for both NOx and CO. This would also be a 1 x 100% installation. This GE estimate is consistent with the Dresser-Rand estimate referenced above.

Table 1 below summarizes some of the differences between the centrifugal and reciprocating compressors for the 200 MMscfd base case. Note that horsepower information for the mechanical drive centrifugal compressor has been converted to megawatt power units to aid in comparing with the electric power requirements of the electric drive reciprocating compressors.

200 MMscfd Case		
General Description	**Centrifugal**	**Reciprocating**
Compressor Configuration	1 x 100%	4 x 25%
Compressor arrangement	Compressor gear coupled to gas turbine	Compressor with direct electric motor drive
Compressor Stages / Cases	2 - Case	2 - Stage
Drive type	Simple Cycle Mechanical Drive Gas Turbine	Electric Motor
Brake Horse Power at Compressor Shaft	~23,250 BHP	17,224 BHP
Efficiency Factor from Power Supply	1.02 (Mechanical losses in gear 2%)	1.12 (Electric Motor 10% loss, Mechanical losses 2%)
Total Continuous Power (BHP)	23,715 BHP	19,290 BHP
Total Continuous Power (MW)	**17.7 MW**	**14.4 MW**
Additional Startup Power Required	na	Inductance loading at start-up 25% of 1 compressor Oversize by 1 MW or supply from Power Grid
Required Gas Turbine Capacity	17.7 MW	15.4 MW

Table 1 – General Description of Centrifugal and Reciprocating Compressor Installations

Compressor Characteristics and Comparison – Base Case 200 MMscfd

Either compressor alternative is ultimately driven by a gas combustion turbine, with assumed emission rates of 25 ppm for both NOx and CO. A heat rate of 9,046 btu/kWh is typical for a PGT25, with the Taurus 70 less efficient at 10,100 Btu/kWh. The emissions in tons per year (tpy) are a function of fuel consumed to meet the load. Based on these assumptions the larger centrifugal load will result in greater emissions than the reciprocating alternative, despite the more efficient driver. Note that emissions are calculated based on assumed pipeline quality natural gas. Actual emissions will vary based on fuel gas quality.

Turndown is related to the ability to operate the equipment at less than full load. With the centrifugal compressor, the limit of turndown is approximately 70% of full load before the gas turbine is no longer able to meet the guaranteed emission requirements. This is equivalent to 140 MMscfd. The turndown of the reciprocating compressor installation would be stepwise in 25% increments. This enables turndown to 25% of full load, or 50 MMscfd. A more continuous turndown curve could be attained through use of variable frequency drives on the 5000 hp reciprocating compressor motor, although the complexity, cost and additional footprint weigh against this option. Some additional volume flexibility is possible with variable pockets on each cylinder.

A significant turndown ability may be an important consideration in compressor selection, especially in the early stages of the project. The well drilling program may take multiple years to complete, during which the initial production volume will be small. During this time, the gas injection compressors will likely be required to handle a wide range of injection volume.

While there may be minor differences in lube oil and interstage cooling requirements, these are not expected to be significant.

The reliability assessment is qualitative rather than quantitative. Dresser Rand, responding with both centrifugal and reciprocating compressor information, indicated that the reliability of the centrifugal unit is expected to be higher than that of the reciprocating unit. This assessment is reflected in the operating time between overhauls, which favors the centrifugal. The major wear components identified in Table 2 also indicate the many components of the reciprocating compressor that will require maintenance over time. However, the redundancy of the 4 x 25% reciprocating installation enables each unit to be removed from service to perform maintenance, with a loss of only 25% of production capacity.

Table 2 below summarizes some of the major characteristics associated with centrifugal and reciprocating compressors.

200 MMscfd Case		
Compressor Comparison	**Centrifugal**	**Reciprocating**
Emissions rate (ppm)	25 ppm NOx, 25 ppm CO	25 ppm NOx, 25 ppm CO
Emissions rate (lb/mmBtu)	.1025 lb/mmBtu NOx, .0625 lb/mmBtu CO	.1025 lb/mmBtu NOx, .0625 lb/mmBtu CO
Fuel rate (mmBtu/hr)	160 mmBtu/hr	145 mmBtu/hr
Emissions (tpy)	72 tpy NOx, 44 tpy CO	65 tpy NOx, 40 tpy CO
CO2 Emissions (tpy)	93,228 tpy CO2	84,668 tpy CO2
Turndown	Continuous - 70% to 100%	Step - 25%, 50%, 75%, 100%
Cooling	Lube oil cooler, intercoolers, by-pass cooler	Lube oil cooler, interstage cooler & by-pass cooler
Reliability	High (No Spare)	Lower (Spares are Typical)
Continuous Operating Time Before Major Overhaul	2-3 Years	1-2 Year
Major Wear Components	Mechanical Seals, Bearing surfaces	Valves, Piston Rings, Rider rings, Cylinder Liners, Piston Rods, Rod Packing
Noise (inside module)	85 (dBA) High Frequency	100 (dBA) Low Frequency
Vibration and Pulsation	Minimal based on proper system design.	Caused by piston motion, heavy foundation and protection needed on discharge.

Table 2 – Compressor Characteristics and Comparison for Base Case 200 MMscfd

Either compressor alternative will be contained in a module. The noise inside the module from the centrifugal is estimated at 85 dB(A) at predominately high frequency. The reciprocating noise inside the module is estimated at 100 dB(A) consisting of mostly low frequency. The high frequency noise is easier to attenuate than the low frequency noise. In either case, the measure of noise performance should be at the boundary of the site. HDR notes that the module wall noise transmission loss rating of 25 STC is a measure of noise reduction across a wide range of frequencies. Thus, module attenuation of high frequency noise will likely be greater than 25 dB, while hard-to-attenuate low frequency may be reduced by less than 25 dB. HDR has not conducted an evaluation noise attenuation performance of the module wall.

Vibration and pulsation is a function of the compressor design, and is inherent in the reciprocating compressor. Typically, heavy foundations and carefully designed pulsation bottles can control vibration.

Compressor Footprint Required – Base Case 200 MMscfd

A significant difference between the centrifugal and reciprocating compression plants is in the total footprint required. The centrifugal is a 1 x 100% mechanical drive unit that requires significantly less space than the 4 x 25% electric drive reciprocating installation. Table 3 summarizes the estimated footprint requirements of the two alternatives.

200 MMscfd Case		
Footprint	**Centrifugal**	**Reciprocating**
Compressor + Driver	2 compressor casings + PGT25 = 60' x 15'	2 stage + 5000 hp electric at 25' x 25' each x 4 units
	NA	10' between units for rod pull
	Electric Switchgear (module power)	Electric Switchgear (module power + 4 x 5000hp)
	Pipe rack for suction/discharge piping	Pipe rack for suction/discharge piping x 4
	Laydown space for maintenance	Laydown space for maintenance
	Control room	Control room
	TOTAL = 110' x 50' = 5,500 sqft	TOTAL = 160' x 75' = 12,000 sqft
Power Module (incremental)	NA	Taurus 70 (34' x 10') x 3 units
		Spacing + balance of plant
		TOTAL = 90' x 60' = 5,400 sqft
TOTAL Footprint Required	5,500 sqft	17,400 sqft

Table 3 – Estimated Footprint Required for Base Case 200 MMscfd

The reciprocating compression plant will require more space than the centrifugal arrangement to accommodate the 4 compressor/motor units, the header suction and discharge piping, and the switchgear for starting the large electric motors. It was assumed maintenance space and control space are similar for each alternative.

The reciprocating compression plant will also require the generation of incremental electric power. As seen in Table 3, the footprint of the incremental power module is nearly identical to the footprint of the centrifugal compression plant. HDR had initially assumed a similar LM2500 gas turbine/generator producing 20 MW to power the electric motors. The installation of the assumed 7500 kW Solar Taurus units provides needed reliability, especially if part of a larger power module required to satisfy the power needs of the balance of the site. These multiple smaller generating units would also more closely match the load curve of the smaller reciprocating units in the event of a significant turndown in volume. In either power plant case, the footprint of the incremental power plant is approximately equal to the footprint of the 1 x 100% centrifugal compressor plant.

Capacity Expansion Discussion

The initial design case for injection volume was defined as 200 MMscfd. Recognizing the need for redundancy and the inefficiency of the centrifugal at such low volume, this planned volume may be more suited to multiple-unit reciprocating than to centrifugal compression. However, as the volume assumption increases, the efficiency advantage of the reciprocating compressor diminishes.

The following sections evaluate characteristics of centrifugal and reciprocating compressors when the volume is increased to 450 MMscfd.

General Description – Alternate Case 450 MMscfd

Dresser Rand's sizing program provided a centrifugal design based on a two-casing compressor gear coupled in series to a gas turbine with 42,340 hp (32.2 MW) required. This would be a 1 x 100% installation. The PGT25-G4 mechanical drive gas turbine was selected which is the improved version of the PGT25 with increased output and improved heat rate.

The Dresser Rand reciprocating compressor design was based on the 50 MMscfd compressor units driven by 5000 hp electric motors as previously described. To attain the alternate case volume of 450 MMscfd, nine of these units would be required. This 9 x 11% installation requires 38,754 hp at the compressors, but due to electrical motor inefficiency and mechanical losses, continuous power generation was estimated to be 43,404 hp (32.4 MW). As before, inductance power requirements at startup of the electric motors would require an additional 1 MW of installed capacity. The total incremental power requirement of 33.4 MW could be met with the addition of five Solar Taurus 70 turbines rated at 7.5 MW each. The Solar Taurus 70 was selected consistent with the proposed balance-of-plant power generation units. At this level of generation, it would be prudent to consider a fewer number of larger, more efficient generating units.

Table 4 below summarizes some of the differences between the centrifugal and reciprocating compressors for the 450 MMscfd case. Again, the horsepower information for the mechanical drive centrifugal compressor has been converted to megawatt power units to aid comparison with the electric power requirements of the electric drive reciprocating compressors.

450 MMscfd Case		
General Description	**Centrifugal**	**Reciprocating**
Compressor Configuration	1 x 100%	9 x 11%
Compressor arrangement	Compressor gear coupled to gas turbine	Compressor with direct electric motor drive
Compressor Stages / Cases	2 - Case	2 - Stage
Drive type	Simple Cycle Mechanical Drive Gas Turbine	Electric Motor
Brake Horse Power at Compressor Shaft	~42,340 BHP	38,754 BHP
Efficiency Factor from Power Supply	1.02 (Mechanical losses in gear 2%)	1.12 (Electric Motor 10% loss, Mechanical losses 2%)
Total Continuous Power (BHP)	43,187 BHP	43,404 BHP
Total Continuous Power (MW)	**32.2 MW**	**32.4 MW**
Additional Startup Power Required	na	Inductance loading at start-up 25% of 1 compressor Oversize by 1 MW or supply from Power Grid
Required Gas Turbine Capacity	32.2 MW	33.4 MW

Table 4 – General Description of Centrifugal and Reciprocating Compressor Installations

Note that the continuous power requirements at this increased volume are now nearly identical. This is due to the improved efficiency of the centrifugal compressor at the larger volume.

Fuel Use and Emissions Comparison – Alternate Case 450 MMscfd

Either compressor alternative is ultimately driven by a gas combustion turbine, with assumed emission rates of 25 ppm for both NOx and CO. For the centrifugal compressor driver, the larger PGT25-G4 was selected to match the required load, which also has improved the heat rate to 8,277 btu/kWh. The reciprocating compressor's power requirements will be met with the addition of five Solar Taurus 70 units. At 10,100 btu/kWh, the smaller 7.5 MW units are less efficient than the large 34 MW PGT25-G4 unit.

Table 4 indicates that the continuous power requirement for either compressor type is nearly identical. Since the emissions in tons per year (tpy) are a function of fuel consumed to meet the load, the more fuel-efficient driver will produce fewer pollutants. Table 5 below summarizes the fuel use and emissions associated with the centrifugal and reciprocating compressor drivers. Note that emissions are calculated based on assumed pipeline quality natural gas. Actual emissions will vary based on fuel gas quality.

450 MMscfd Case		
Fuel Use and Emissions	**Centrifugal**	**Reciprocating**
Emissions rate (ppm)	25 ppm NOx, 25 ppm CO	25 ppm NOx, 25 ppm CO
Emissions rate (lb/mmBtu)	.1025 lb/mmBtu NOx, .0625 lb/mmBtu CO	.1025 lb/mmBtu NOx, .0625 lb/mmBtu CO
Fuel rate (mmBtu/hr)	266 mmBtu/hr	328 mmBtu/hr
Emissions (tpy)	120 tpy NOx, 73 tpy CO	147 tpy NOx, 90 tpy CO
CO2 Emissions (tpy)	155,070 tpy CO2	190,630 tpy CO2

Table 5 – Compressor Characteristics and Comparison

At the required power level of nearly 34 MW, consideration should be given to increasing the size of electric generating units for the reciprocating compressor alternative. Rather than install five Taurus units in addition to the balance of plant units, two larger units with more efficient heat rates could potentially reduce fuel use and resulting emissions of the reciprocating alternative. At the 450 MMscfd assumed volume level, the horsepower requirement is nearly identical for either the centrifugal or reciprocating alternative, therefore little difference in emissions will exist given similarly efficient gas turbine drivers

Compressor Footprint Required – Alternate Case 450 MMscfd

A significant footprint difference remains between the centrifugal and reciprocating compression plants. The centrifugal is a 1 x 100% mechanical drive unit that requires significantly less space than the 9 x 11% electric drive reciprocating installation. Table 6 summarizes the estimated footprint requirements of the two alternatives.

450 MMscfd Case		
Footprint	**Centrifugal**	**Reciprocating**
Compressor + Driver	2 compressor casings + PGT25G4 = 60' x 15'	2 stage + 5000 hp electric at 25' x 25' each x 9 units
	NA	10' between units for rod pull
	Electric Switchgear (module power)	Electric Switchgear (module power + 9 x 5000hp)
	Pipe rack for suction/discharge piping	Pipe rack for suction/discharge piping x 9
	Laydown space for maintenance	Laydown space for maintenance
	Control room	Control room
	TOTAL = 110' x 50' = 5,500 sqft	TOTAL = 190' x 140' = 26,600 sqft
Power Module (incremental)	NA	Taurus 70 (34' x 10') x 5 units
		Spacing + balance of plant
		TOTAL = 140' x 60' = 8,400 sqft
		Alternate Power Increment:
		LM2500 (60' x 15') x 1 units
		Spacing + balance of plant
		TOTAL = 110' x 50' = 5,500 sqft
TOTAL Footprint Required	5,500 sqft	~35,000 sqft

Table 6 – Estimated Footprint Required for Alternate Case 450 MMscfd

The reciprocating compression plant will require more space than the centrifugal installation to accommodate the 9 compressor/motor units, the header suction and discharge piping, and the switchgear

for starting the large electric motors. It was assumed maintenance space and control space are similar for each alternative.

The reciprocating compression plant will also require the generation of incremental electric power. As seen in Table 6, the footprint of the incremental power module for the Taurus option is now larger than that of the single mechanical drive turbine and centrifugal compressor.

It's worth noting that the footprint of the centrifugal installation did not increase due to an increase in gas volume. This is due to two factors: (1) the greater power capacity of the PGT25-G4 as compared to the PGT25, while occupying nearly the same skid size, and (2) the use of identical compressor casings for either volume scenario.

Installed Capacity Discussion

The design philosophy utilized by ExxonMobil is to build what is required for the 200 MMscfd base case volume with sufficient flexibility to accommodate unknown reservoir production and injection characteristics. ExxonMobile has also provided for expansion of production, gathering, and processing capacity as production is proven. Expansion plans for compression capacity is not known.

If complete condensate recovery over a shorter period of time is desired, an increase in gas production and reinjection volume is required. The larger volume assumption of the 450 MMscfd alternative case has eliminated the efficiency advantage the reciprocating compressor held at the 200 MMscfd level. However, at the 450 MMscfd volume level, two potentially significant differences exist between the centrifugal and reciprocating compressors: (1) turndown ability of the reciprocating installation is significantly better than the 315 MMscfd turndown limit of the centrifugal, and (2) the footprint of the centrifugal installation is significantly less than the reciprocating installation.

The alternative volume assumption of 450 MMscfd of initially installed compression capacity may be inconsistent with the planned drilling program timeline, and the uncertainties of actual reservoir characteristics. Specifically, the turndown limit of the 450 MMscfd 1 x 100% centrifugal installation is 315 MMscfd. A sufficient number of wells must be installed to ensure this level of production before any gas can be re-injected. Production well capacity for this volume may not occur for an extended period of time beyond the point at which production could occur under a reciprocating compressor installation (i.e. 50 MMscfd). In addition, reservoir information that could be obtained during early production under the reciprocating installation is precluded until at least 315 MMscfd of production is available.

As reservoir characteristics become better known, an increase in the gas injection rate above 200 MMscfd may be desired. The benefits of adding a large, base loaded centrifugal compressor operating under known gas composition and pressure requirements could be considered in conjunction with the existing reciprocating installation used for outage coverage, peak loads, or even additional base load capacity.

It may be beneficial to match the depletion of the condensate reserves with the installation of the natural gas transmission pipeline. This would enable the transition from a condensate-recovery-and-gas-reinjection operation to a gas-production-with-condensate-stripping operation. If condensate recovery occurs too slowly, or if the gas transmission pipeline is in-service earlier than expected, condensate could be stranded in the reservoir unless gas reinjection is mandated. If condensate recovery occurs too quickly, the field may reach the end of economically viable condensate recovery, at which time shutdown and potential decommissioning of surface equipment could occur.

There may be other considerations of which we are unaware. The tradeoffs listed above identify, at a very high level, the characteristics of centrifugal and reciprocating compressors.

POINT THOMSON PROJECT EIS

Memo

To:	Hank Baij, Corps of Engineers		
From:	Michael Allwright, HDR	Project:	Point Thomson Project EIS
CC:		Subject:	RFI#65b – Compressor Comparison
Date:	September 14, 2010	Job No:	123515

Purpose

HDR previously evaluated the characteristics of reciprocating and centrifugal compressors in application to the Point Thomson Project compression requirements. Memo RFI#65 – augmented, dated June 29, 2010, provides this information. The purpose of this memo is to investigate further the existence of in-service centrifugal compressors of a size commensurate with the compression requirements of the Point Thomson project.

Point Thomson Project's Purpose and Need

HDR understands that the purpose of the initially installed compressors is to re-inject dry gas back into the reservoir in order to maintain field pressure necessary to maximize production of condensate. While exploratory wells exist, there exists significant uncertainty concerning both reservoir characteristics and the gas/liquids separator performance. That uncertainty will not be resolved until steady state operation following initial production begins. Recognizing these uncertainties, and start-up problems likely to exist, the purpose and need for compression at the Point Thomson project is:

- Design compression capacity ~ 200 MMscfd
- Approximate suction pressure ~2,700 psi
- Approximate discharge pressure ~10,000 psi
- Start up by year end 2014
- Maximize use of proven technology and minimize in-field modifications
- Enable turndown operation of production and injection wells at variable volumes
- Design for multiple units to increase reliability and avoid total production and processing shutdowns
- Design for a range of operating conditions; optimizing can occur later
- Minimize environmental impact (air emissions, noise, footprint)

HDR has previously discussed the characteristics of reciprocating and centrifugal compressors, including the advantage held by the reciprocating compressor at the 200 MMscfd volume level. Advantages include lower emissions, lower fuel use, greater turndown capacity, increased redundancy, and increased operating flexibility. The only disadvantage is a slightly greater footprint requirement.

In the previous compressor analysis memo, HDR focused on the performance characteristics of each compressor type while recognizing the significant issues surrounding the installation of a single 200 MMscfd

centrifugal compressor (1 x 100% unit). HDR also pointed out that a 1 x 100% installation cannot meet the requirements for multi-unit redundancy, minimizing total outages, maximizing turndown and variable volume operation identified above.

The installation of additional units can mitigate the redundancy requirement. Any number of configurations, such as 2 x 100% or 2 x 50%, or any configuration in between can provide this redundancy. However, each configuration would need to be evaluated with respect to turndown volume identified as a requirement of early project development. In addition, recognizing the ever-increasing inefficiency of the centrifugal compressor at lower volumes, there is an increasing environmental cost associated with smaller capacity centrifugal units.

The gas turbine driver limits turndown capacity to approximately 70% without exceeding air emission permit limits. An increased turndown is possible, but requires the unit begin recycling the gas, essentially compressing the gas (to the 70% limit on the driver) and then dropping the pressure on that portion of the discharge volume that is not required, and recycling it back to the inlet of the compressor. This is very wasteful of fuel and unnecessarily increases air emissions.

Operating flexibility is inherently more restrictive in the design of the centrifugal than in the reciprocating compressor. This is not an issue when the operating characteristics are well known, and significant variation will not occur over time. This is not the case at Point Thomson, where much is unknown about the characteristics of the reservoir and the performance of the gas/liquids separator.

The issue of whether a small volume (i.e., 100 MMscfd), high pressure centrifugal compressor meets the proven technology requirement is further discussed below.

Installed Natural Gas Reinjection Centrifugal Compressors

HDR has further explored with GE Nuovo Pignone the existence of very high pressure (above ~8000 psia) centrifugal installations in either sweet gas or sour gas reinjection service. Table 1 below identifies the four projects and associated installed units that come closest to satisfying the very high discharge pressure required for Point Thomson.

Project	Location	Capacity MMscfd	Suction psia	Discharge psia	Power kW	Year Shipped
Pigap I	Venezuela	181	1114	9005	22,820	1995
Pigap I	Venezuela	181	1114	9005	22,820	1995
Pigap I	Venezuela	181	1114	9005	22,820	1996
Pigap I	Venezuela	181	1114	9005	22,820	1996
Pigap I	Venezuela	181	1114	9005	22,820	1999
Pigap I	Venezuela	181	1114	9005	22,820	1999
Pigap I	Venezuela	181	1114	9005	22,820	1999
Pigap I	Venezuela	181	1114	9005	22,820	1999
Pigap I	Venezuela	181	1114	9005	22,820	1999
Karachaganak	Kazakistan	231	1015	7975	26,770	2000
Karachaganak	Kazakistan	231	1015	7975	26,770	2000
Karachaganak	Kazakistan	231	1015	7975	26,771	2000
Tengiz	Kazakistan	204	848	9034	30,714	2003
Tengiz	Kazakistan	197	1189	9034	25,500	2005

Kashagan	Caspian Sea	316	1320	11020	35,500	2005

Table 1 – GE Nuovo Pignone High Pressure Centrifugal Compressor Installations

The information in Table 1 was provided by GE Oil and Gas Company – Nuovo Pignone (in metric units converted by HDR), and may differ from earlier publications or articles describing these projects. Nuovo Pignone has shipped approximately 200 natural gas reinjection units over the last 25 years. These four projects stretched the limits of technology at the time, and required a significant investment of time and talent to identify technology limitations and to design safe and reliable compressor units. Each of these installations represented a unique challenge: the Pigap project represented the first centrifugal to achieve 9,000 psi discharge pressure on sweet gas; Karachaganak was the first to compress sour gas to high discharge levels; Tengiz moved sour gas injection pressure to above 9,000 psi; and Kashagan has taken sour gas injection to above 11,000 psi.

The Point Thomson requirement is to compress 200 MMscfd from 2,700 psi suction pressure to 10,000 psi discharge pressure. While this appears to be generally in the range of existing installations (~200 MMscfd and 9,034 psi at Tengiz, 316 MMscfd and 11,020 psi at Kashagan), this application is certainly not "off-the-shelf" and would require that significant design considerations be addressed. However, as previously discussed, while a single 200 MMscfd unit satisfies the capacity requirements of Point Thomson it fails to meet the turndown, operating flexibility, and redundancy requirements of the project. A review of Table 1 illustrates the importance of redundancy, as a minimum of two compressor units exist at each of the four projects. Adding a second 200 MMscfd unit improves redundancy, but does nothing to improve turndown or operating flexibility, and doubles the Potential to Emit (air pollutants) due to the greater installed gas turbine capacity. It also requires additional footprint, reducing the only advantage the centrifugal compressor held over the reciprocating compressor.

Alternative multi-unit arrangements can examined as a way to improve reliability and increase turndown. ExxonMobil Technical Brief #2 has identified a 100 MMscfd unit as their method to meet the multi-unit redundancy requirement of the project. This 2 x 50% installation would address not only the redundancy requirement, but also enables turndown to a much lower level than the single 200 MMscfd unit would. However, operating flexibility of the centrifugal compressor is inherently more restrictive than the reciprocating compressor, no matter the configuration. A reciprocating compressor is better able to handle a wider range of suction and discharge pressure than the centrifugal compressor. A review of Table 1 indicates that capacity of 100 MMscfd is significantly below that of the four very high pressure installations to date. However, Nuovo Pignone recently delivered several 100 MMscfd units to Iran with a suction pressure of 1,030 psi and a discharge pressure of 7,580 psi. Design of such a unit with the required increase in discharge pressure would require careful consideration of all parameters that could affect safety, maintainability, reliability, and operations.

Summary

While neither design nor installation of the 200 MMscfd or the 100 MMscfd centrifugal compressors discharging at 10,000 psi has occurred, there are units of similar or greater capacity and similar or greater discharge pressure in service today. The required 200 MMscfd unit is "close" to the capacity of Tengiz, and less than the discharge pressure of Kashagan. However, the design of both Tengiz and Kashagan required a three casing arrangement due to their pressure ratios, while Point Thomson would require two casings. The gas composition of Tengiz and Kashagan are different from each other, and are certain to be different from Point Thomson. These site-specific design considerations will affect impeller number and sizing, casing design and pressure rating, seal method, and a myriad of other factors that cause the Point Thomson design to be unique.

All the above issues compound the design of the low volume 100 MMscfd units. Even if possible to develop a 100 MMscfd centrifugal compressor (in a 2 x 50% configuration meeting Point Thomson requirements) in

time to meet startup by year end 2014, it remains challenged in several other ways in comparison to the reciprocating compressor option. One of the most interesting issues is the air emissions penalty associated with this configuration. As indicated previously, not only does centrifugal compressor efficiency decrease as capacity decreases, but also the smaller gas turbine driver is typically less efficient than a larger gas turbine. These factors combine to result in an approximate 26% increase in fuel use over the reciprocating compressor option, leading directly to a similar increase in NOx, CO and CO_2 emissions.

Table 2 summarizes the characteristics of the three compressor options and their ability to meet project requirements.

Project Requirement	Reciprocal	Centrifugal	
	4 x 50 MMscfd	1 x 200 MMscfd	2 x 100 MMscfd
Capacity ~200 MMscfd	Yes	Yes	Yes
Suction 2,700 psi	Yes	Yes	Yes
Discharge 10,000 psi	Yes	Yes	Yes
Startup Year end 2014	Yes	Maybe	No
Proven Technology	Yes	Maybe	No
Turndown level (Lower is better)	~50 MMscfd	~140 MMscfd	~70 MMscfd
Reliability thru Multiple Units	Yes	No	Yes
Operating Flexibility	Yes	No	No
Environmental Impact - Air	Best	~10% higher	~26% higher
Environmental Impact - Noise	~Same	~Same	~Same
Environmental Impact - Footprint	~17,400 ft^2	~5,500 ft^2	~11,000 ft^2

Table 2 – Summary of Compressor Characteristics vs. Project Requirements

In HDR's memo *RFI#65a – Compressor Comparison*, it was noted that the reciprocating compressor installation was favored given the initial project requirements. This has not changed. Also noted was the following:

As reservoir characteristics become better known, an increase in the gas injection rate above 200 MMscfd may be desired. The benefits of adding a large, base loaded centrifugal compressor operating under known gas composition and pressure requirements could be considered in conjunction with the existing reciprocating installation used for outage coverage, peak loads, or even additional base load capacity.

ExxonMobil also noted in *Technical Brief #2 – Centrifugal Compressors (Rev 1)* that future project expansion could favor centrifugal compressors, as gas volume would likely be larger. In addition, the project would better understand operating parameters, gas composition, and reservoir characteristics, which would not be as variable as during initial project development.

POINT THOMSON PROJECT EIS

Memo

To:	Julie McKim, Corps of Engineers		
From:	Michael Allwright, HDR Alaska	Project:	Point Thomson Project EIS
CC:		Subject:	RFI#71 – Automated Production Process
Date:	May 5, 2010	Job No:	123515

Purpose

HDR was asked to evaluate the possible operation of the Central Processing Facility (CPF) and the compression facility from a remote location. Unknown is at what distance the operation staff would be located, but it is assumed to be at an existing facility, the closest of which is at a distance of approximately 25 miles to the west at Badami. This information request is to assist in developing a discussion of alternatives within the Point Thomson Project Environmental Impact Statement. This is, of necessity, a high level evaluation, as details of existing conditions and possible consequences could exist of which HDR Ann Arbor is unaware.

Concept Description

ExxonMobil's proposed design consolidates all Central Pad drilling, processing, compression, construction lay down, warehouse, maintenance and permanent and construction camp facilities at the expanded existing Central Pad (see Point Thomson Project Description Figure 5.3). The alternative concept involves relocating all personnel facilities to a remote location. The goal of this concept is to eliminate expansion of the Central Pad, and assumes sufficient pad space is available at the remote control site to install the operations and camp facilities.

Discussion of Remote Operation

Unattended operation of small oil and gas facilities is quite common where single well pumping or gas compression units are operated without staff. Typically, these units are visited each day by an operator who checks operating parameters, verifies that fluid levels are correct, and performs routine, daily maintenance activities. Regardless of whether the plant is operated locally or remotely, day-to-day maintenance activities will need to be performed.

Outside of day-to-day maintenance requirements, unmanned operation by remote control/monitoring of operating parameters is possible, either by phone line, satellite, or fiber optic communications. Remote operations staff can control and monitor the site while the onsite control system can sense unsafe conditions, including temperature, pressure, vibration or liquid levels, and take corrective action. If the automated corrective action fails to return the plant to a safe condition within a programmed time, an alarm would be issued to the remote monitoring facility.

After notification of a site alarm through the remote monitoring facility (or potentially from an auto dialer paging system) the plant operators could attempt to take corrective action. The response time for an operator to take corrective action will depend greatly on accessibility to the process site. Depending on the severity of the condition, production and processing could terminate, and the facility would be placed in a

prescribed safe shutdown condition. Depending on the programmed action, this may require the shut-in and depressurization (to the flare) of the entire plant.

Facility shutdown could be implemented remotely by operator action within the control system; however, most process and generation facilities also design a backup hardwired trip into their control and operating philosophy. This hardwired trip enables emergency plant shutdown when control systems are inoperable, which could be caused by either fiber communication failure or control system software malfunction. A hardwired trip is a safety precaution that would require that a separate copper line be installed between the process site and the remote control location in addition to control system fiber optic. It is assumed that control system fiber and backup hardwired trip copper cabling would share the same routing infrastructure. There is a potential risk that any damage to the routing infrastructure that would cause the failure of the fiber (and thus the control system) would simultaneously cause failure of the hardwire trip communications.

It is also worth noting that Ethernet based communications (the backbone of most modern control systems) which utilize fiber optics typically have distance limitations of 2 kilometers. The limitation can be overcome through the use of repeating stations; however, those stations require reliable power sources.

HDR has investigated utilizing a wireless control system on a facility of this size of that proposed for the Point Thomson Project. Non of the vendors contacted were aware of any facilities of this magnitude that have incorporated wireless technology for control. To date, wireless technology has been limited to remote alarm monitoring.

Typically, unattended operation is appropriate for smaller facilities that cannot justify the cost of a full-time operator. The cost of full-time staff must be weighed against the value of the lost production during automated shutdown conditions, as well as possible equipment damage and environmental consequences associated with liquid releases. In the case of Point Thomson, the value of the CPF and compression assets will be significant, as will the cost of lost production. The risk to the environment of unattended equipment failure is also significant. Automated systems can fail, and if personnel are located at a significant distance, or are unable to attend to the failure in person (e.g., due to weather conditions), undesirable consequences can result.

In any case, the proposed CPF and compression facility at Point Thomson will be operated by an automated control system. However, the control system actions of a fully staffed facility would be different than a facility that is unmanned. For example, the response to an alarm condition in a staffed operation could be to send an operator to investigate the cause of the alarm. In an unmanned operation, the response may have to be to shut down the plant to avoid damage to equipment or a release to the environment.

It is our opinion that due to the size and scale of the proposed processing facility, the goal of completely removing people from the central processing site is unrealistic. Camp facilities will be required to support the food and shelter needs of the daily operations and maintenance people required to maintain the CPF and associated equipment as well as of those personnel contracted to perform intermittent, major equipment maintenance activities. In addition, overnight accommodations when the staff is unable to leave the site due to weather conditions will have to be provided.

There may be other considerations of which we are unaware. The tradeoffs listed above identify, at a very high level, the possible consequence of remote operations.

POINT THOMSON PROJECT EIS

Memo

To:	Julie McKim, Corps of Engineers		
From:	Michael Allwright, HDR Alaska	Project:	Point Thomson Project EIS
CC:		Subject:	RFI#73 – Badami Power Capacity and Load
Date:	May 5, 2010	Job No:	123515

Purpose

HDR was asked to evaluate the power generation capacity of Badami, and whether excess generation capacity existed to support the power needs of Point Thomson.

Concept Description

If sufficient excess power was available at Badami, an electric transmission line could be installed along the export pipeline route to the Point Thomson site. This would avoid the installation of power generation capacity at Point Thomson.

Discussion of Badami Generation

The HDR team reviewed the air permit Emissions Unit Inventory of the Badami Production Facility. There appears to be four units for power generation with a total rated capacity of approximately 26 MW:

- Emission Units 420 and 421 are listed as Main Generators at 1855 hp each. These diesel fueled engines are likely backup generation units of approximately 1,300 kW each. As backup units, these cannot be considered as a full-time source of power generation.
- Emission Units 500 and 501 are listed as Solar Mars 90 combustion turbines rated at 11,862 kW each. These units are gas fueled turbines and are likely the source of prime power for the site.

HDR can only speculate as to the purpose of each of the listed units, since pertinent, site specific data has not been specifically obtained from BP Exploration Inc. who is the current owner of the facility. Informal contacts regarding the Badami site suggest that there is “not much” power generation capacity at Badami. HDR was unable to obtain Badami power consumption data to identify what portion of the generation might be considered as surplus capacity. However, even if on-site loads were 12 MW, half the available capacity, the need for a redundant power supply would preclude the sale of this “excess” power to Point Thomson. Furthermore, having experienced 12 to 13 years of operating service, the condition and reliability of these existing units is currently unknown.

Excluding the power required for natural gas compression, the power needs of Point Thomson peak at 20 MW (Point Thomson Project Description Section 7.3.7), which clearly can not be supported from Badami. As such, the proposed installation of multiple, redundant generation sources would generally be deemed prudent for the Point Thomson installation and would avoid any concerns with routing, installation, and reliability of a longer distance electrical transmission line in a severe environment.

There may be other considerations of which we are unaware. The information listed above identifies publicly available information, as current site-specific information was not obtained.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 75 No-Action Alternative

The EIS team is seeking clarity on ExxonMobil's level of activity and presence at Point Thomson if the federal action resulting from the EIS is to not issue a Corps permit. Provide a description of potential activity that might occur at Point Thomson if ExxonMobil was not allowed to place fill in association with the proposed project (or any major activity that would require fill in the Point Thomson area).

For example, in general, if the permit was denied:

- *ExxonMobil would discontinue existing activities and demobilize equipment and resources from Point Thomson.*
- *ExxonMobil would continue delineation activities on its existing PTU#3 and East Pad footprints.*
- *ExxonMobil would continue to delineate and could produce hydrocarbon liquids using the existing PTU#3 footprint.*

Date Received 4/26/10

Date of Response: 5/11/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

From: Peter Hanley, EIS SPOC

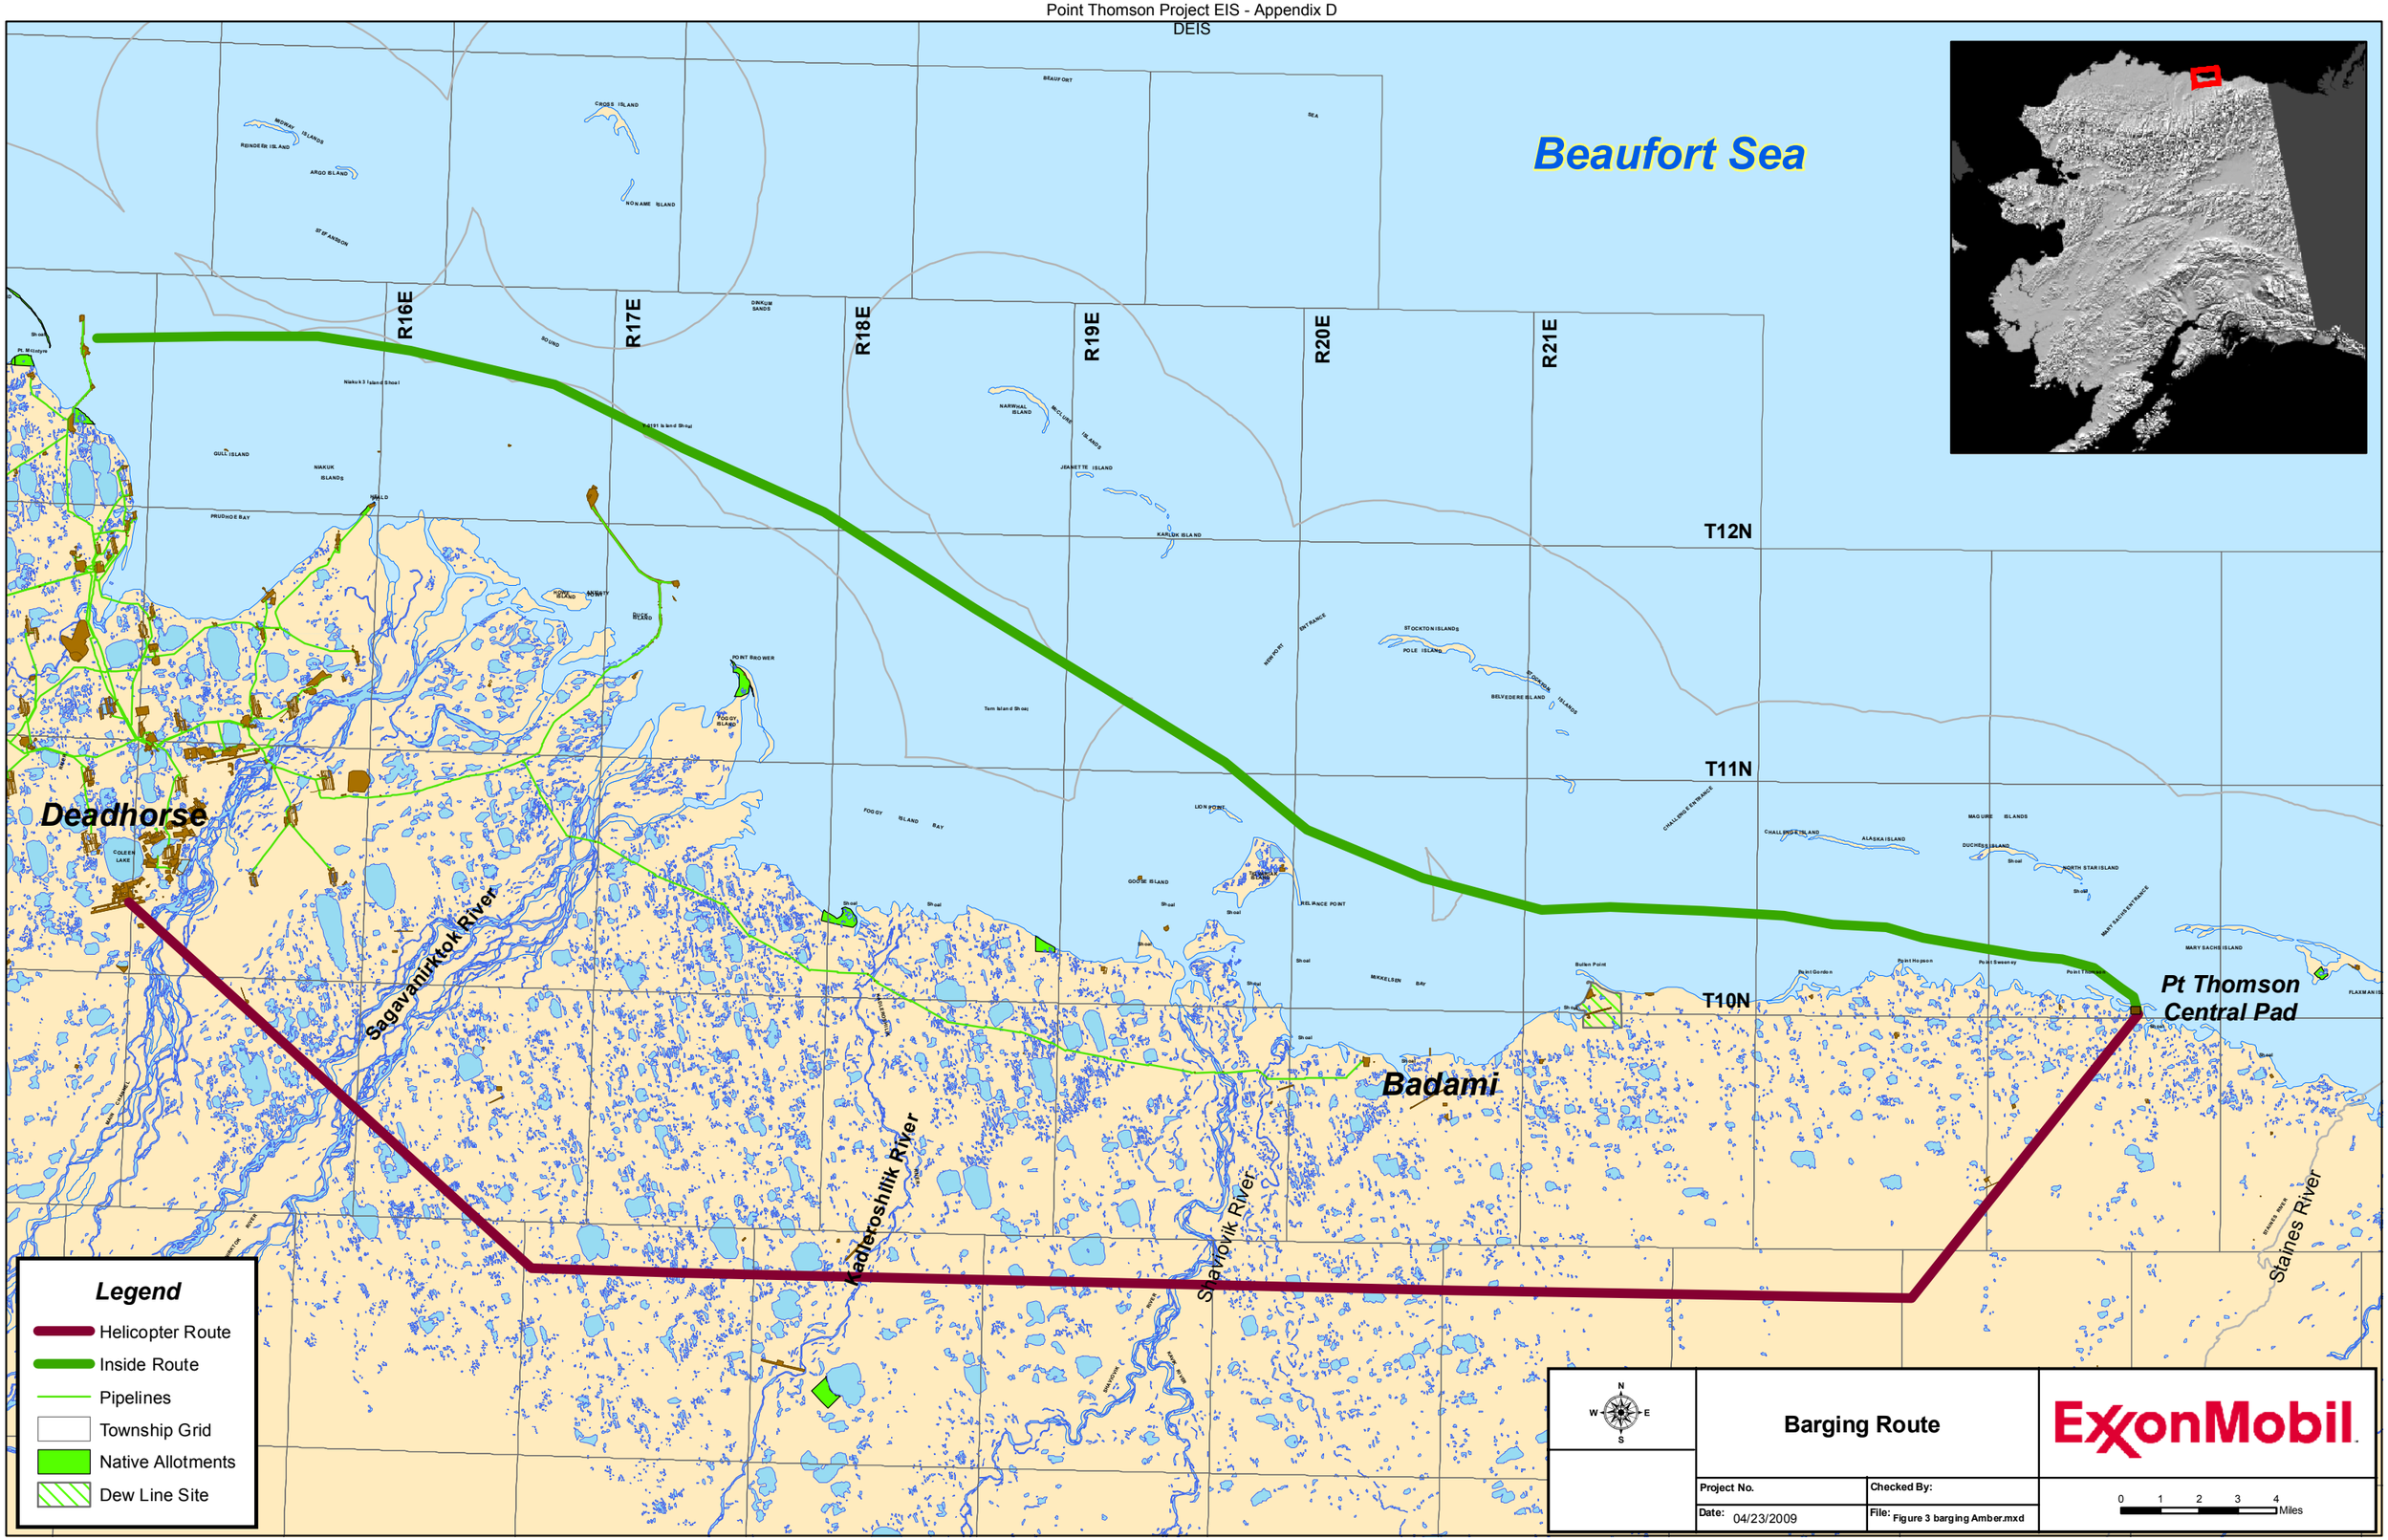
Response

ExxonMobil believes a No-Action Alternative would not be in the public interest or an appropriate outcome of the EIS process. ExxonMobil has incorporated multiple design elements and mitigation measures in the proposed action which provide for mitigation of environmental impacts. Additionally, there may be other practicable mitigating measures or alternatives developed via the EIS and permitting processes that would further mitigate or avoid impacts. ExxonMobil believes the environmental impacts from the proposed project are acceptable when compared to the public benefits that would be derived from implementation of the Project.

If the federal action is to not issue, e.g., deny, a Corps permit for gravel fill and other construction activities regulated by the agency under Section 404 of the Clean Water Act and Section 10 of the Rivers and Habors Act, then the Project could not proceed as described in the October 2009 Project Description and Project Environmental Report. At this time, it is not foreseeable how any project leading to production of the Point Thomson hydrocarbon resources could proceed in any reasonable timeframe without a Corps permit. Factors supporting these conclusions include:

1. There is insufficient space on the existing Central Pad for planned necessary

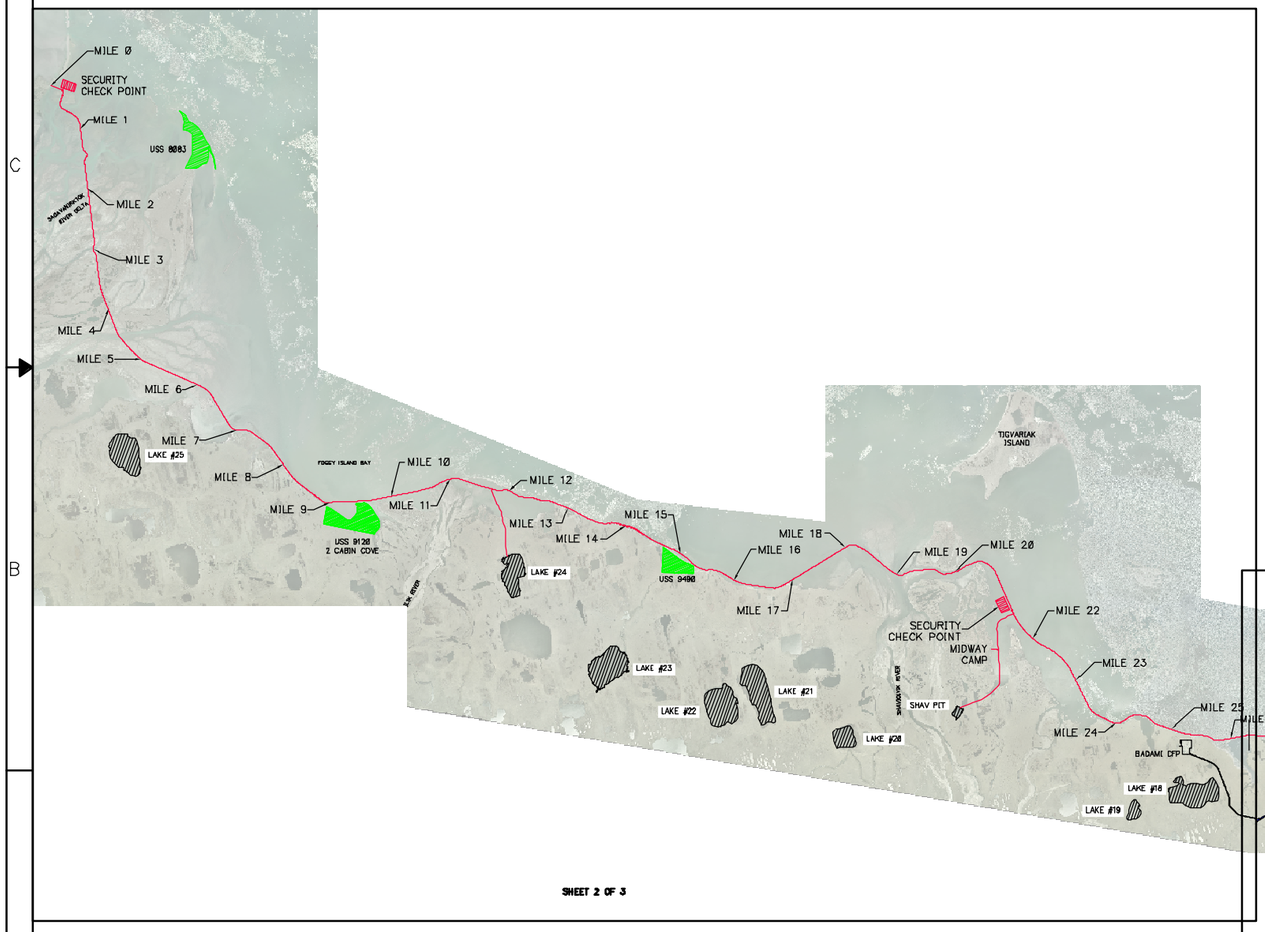
production facilities and related support infrastructure (this includes necessary safety separation of living quarters from those production facilities);



2. At a remote, isolated location such as Point Thomson, a production facility requires significant logistical support on a year-round basis, which is generally provided by infrastructure such as an airstrip, interconnecting road access and storage areas. Without the described logistical support or storage areas, it would be impractical or impossible to safely conduct hydrocarbon production operations compliant with applicable laws and regulations.
3. Installation of VSMs for the export pipeline system to transport production is a regulated Sec. 404 activity.

If the Corps permit were denied, current project engineering and planning for a smooth and efficient transition to construction and production operations would be suspended as the Company evaluates whether there are any potentially feasible options while adhering to accepted good engineering practices to provide a safe and compliant development.

Further drilling from the existing Central Pad and existing East Pad are included in the current development plans and potentially could be conducted under a no action alternative, although the availability of adequate space particularly at the East Pad would need to be determined. However, without a safe, viable and sustainable production scheme, further drilling would be questionable. Following suspension of the Central Pad wells and demobilization of the drilling rig, camp, equipment and supplies, ExxonMobil would continue to monitor the location.



Evaluation of the Thomson Sand and other hydrocarbon resources at Point Thomson is an integral component of the project scope. This process includes more than merely drilling; it requires necessary production facilities and support infrastructure to be installed, which can not be undertaken without a Corps permit. Consequently further evaluation of the hydrocarbon resources could not proceed as planned.

If evaluation and production of hydrocarbon resources at Point Thomson cannot proceed as planned, the public and private purposes and needs of the Project would not be achieved. These include creation of jobs, revenue for the North Slope Borough and the State of Alaska, additional throughput for the TransAlaska Pipeline System, and availability of Point Thomson hydrocarbon resources to help meet public demand, including potential delivery of natural gas from Point Thomson into a natural gas pipeline should one be constructed. ExxonMobil likely could not have first production by year-end 2014, as set forth in the Department of Natural Resources Commissioner's decision, impacting ExxonMobil and the other working interest owners' rights to develop the significant discovered hydrocarbon resources in the Point Thomson Unit.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 75 No-Action Alternative

The EIS team is seeking clarity on ExxonMobil's level of activity and presence at Point Thomson if the federal action resulting from the EIS is to not issue a Corps permit. Provide a description of potential activity that might occur at Point Thomson if ExxonMobil was not allowed to place fill in association with the proposed project (or any major activity that would require fill in the Point Thomson area).

For example, in general, if the permit was denied:

- *ExxonMobil would discontinue existing activities and demobilize equipment and resources from Point Thomson.*
- *ExxonMobil would continue delineation activities on its existing PTU#3 and East Pad footprints.*
- *ExxonMobil would continue to delineate and could produce hydrocarbon liquids using the existing PTU#3 footprint.*

Date Received 4/26/10

Date of Response: 5/11/10
Date of Addendum: 6/2/10 (in response to clarification of 5-17-10)

To: Tim Gallagher HDR Project Manager, Julie McKim USACE (Addendum to Hank Baij)

From: Peter Hanley, EIS SPOC

Response

ExxonMobil believes a No-Action Alternative would not be in the public interest or an appropriate outcome of the EIS process. ExxonMobil has incorporated multiple design elements and mitigation measures in the proposed action which provide for mitigation of environmental impacts. Additionally, there may be other practicable mitigating measures or alternatives developed via the EIS and permitting processes that would further mitigate or avoid impacts. ExxonMobil believes the environmental impacts from the proposed project are acceptable when compared to the public benefits that would be derived from implementation of the Project.

If the federal action is to not issue, e.g., deny, a Corps permit for gravel fill and other construction activities regulated by the agency under Section 404 of the Clean Water Act and Section 10 of the Rivers and Habors Act, then the Project could not proceed as described in the October 2009 Project Description and Project Environmental Report. At this time, it is not foreseeable how any project leading to production of the Point Thomson hydrocarbon resources could proceed in any reasonable timeframe without a Corps permit. Factors supporting these conclusions include:

1. There is insufficient space on the existing Central Pad for planned necessary production facilities and related support infrastructure (this includes necessary safety separation of living quarters from those production facilities);
2. At a remote, isolated location such as Point Thomson, a production facility requires significant logistical support on a year-round basis, which is generally provided by infrastructure such as an airstrip, interconnecting road access and storage areas. Without the described logistical support or storage areas, it would be impractical or impossible to safely conduct hydrocarbon production operations compliant with applicable laws and regulations.
3. Installation of VSMs for the export pipeline system to transport production is a regulated Sec. 404 activity.

If the Corps permit were denied, current project engineering and planning for a smooth and efficient transition to construction and production operations would be suspended as the Company evaluates whether there are any potentially feasible options while adhering to accepted good engineering practices to provide a safe and compliant development.

Further drilling from the existing Central Pad and existing East Pad are included in the current development plans and potentially could be conducted under a no action alternative, although the availability of adequate space particularly at the East Pad would need to be determined. However, without a safe, viable and sustainable production scheme, further drilling would be questionable. Following suspension of the Central Pad wells and demobilization of the drilling rig, camp, equipment and supplies, ExxonMobil would continue to monitor the location.

Evaluation of the Thomson Sand and other hydrocarbon resources at Point Thomson is an integral component of the project scope. This process includes more than merely drilling; it requires necessary production facilities and support infrastructure to be installed, which can not be undertaken without a Corps permit. Consequently further evaluation of the hydrocarbon resources could not proceed as planned.

If evaluation and production of hydrocarbon resources at Point Thomson cannot proceed as planned, the public and private purposes and needs of the Project would not be achieved. These include creation of jobs, revenue for the North Slope Borough and the State of Alaska, additional throughput for the TransAlaska Pipeline System, and availability of Point Thomson hydrocarbon resources to help meet public demand, including potential delivery of natural gas from Point Thomson into a natural gas pipeline should one be constructed. ExxonMobil likely could not have first production by year-end 2014, as set forth in the Department of Natural Resources Commissioner's decision, impacting ExxonMobil and the other working interest owners' rights to develop the significant discovered hydrocarbon resources in the Point Thomson Unit.

Addendum to RFI 75 – No Action Alternative

To facilitate an impact analysis of the No-Action alternative, ExxonMobil has been requested to provide more information on project activities in the event the Section 404/10 permit is denied upon completion of the EIS process. To predict project activities under such circumstances is highly speculative because the details and rationale for

such a regulatory action are unknown. This addendum describes a possible scenario based on the following assumptions:

1. The decision to deny the permit is made in the late summer of 2011;
2. The decision is unexpected;
3. There is no short term likelihood that issues surrounding the decision can be resolved consistent with the current project schedule (i.e., plans and early activities for the development project have not been adjusted).

At the assumed time of the decision on the permit (August 2011), the drilling rig, support equipment and drilling camp will have been demobilized. Fuel storage and water tanks will remain on the Central Pad to be available for future use.

Some initial preparations related to planned construction activities at the Central Pad will likely have been in place by late summer 2011 including mobilization of construction equipment, construction camps, and construction supplies for storage on the pad. These will likely have been fully mobilized to the location by the end of the summer 2011 open water season. Because there will be fuel, construction equipment and supplies on location, there will be personnel onsite for security and maintenance purposes.

Because of the assumed date of the "No Action" decision, few immediate actions could be taken onsite. ExxonMobil would likely make plans to demobilize all pre-staged equipment, camps, and fuel at the Central Pad as soon as practicable and cost efficiently. Previously installed camps would be utilized to house personnel conducting these demobilization activities. Helicopter support for personnel transfer would be required to support the demobilization activities. It is not possible to provide additional details of this demobilization. However, it would be expected that all equipment would be demobilized by the end of the 2012 open water season.

Following demobilization as described above, the drill site and the two wells drilled from the Central Pad will be monitored in accordance with Alaska Oil and Gas Conservation Commission regulations and prudent operator practices. This will involve periodic helicopter flights to the Central Pad.

Decisions regarding drilling or other development activities that might thereafter be undertaken at the Central Pad or elsewhere at Point Thomson cannot be predicted at this time. ExxonMobil would continue to evaluate actions which might be available, appropriate and reasonable to develop Point Thomson consistent with the limits of regulatory approvals. In no event would ExxonMobil abandon its interests in the Point Thomson Unit or leases and will continue to pursue all measures necessary to protect both its rights to and the value of these interests.

Information Needed:	Please supply information for the following: 1. The ER did not provide detailed information on the air quality emission units. Please provide information on the applicability of New Source Performance Standards (40 CFR 60) and National Emission Standards for Hazardous Air Pollutants (40 CFR 61, 63) that may be subject to the stationary source or equipment used during drilling/construction and operations. 1. The ER did not provide detailed information to determine the applicability of Compliance Assurance Monitoring (CAM, 40 CFR 64). CAM requirements apply to stationary sources that are equipped with post-process pollutant control devices, have pre-control device emissions equal to or greater than 100 percent of the major source threshold for a pollutant as defined in 40 CFR Part 70 and Part 71, and are subject to the Title V permit program. If any of the equipment used at the stationary source has a control device, please provide the pre-control device emissions to determine CAM applicability. 2. Will the project area store any hazardous materials subject to the Chemical Accident Prevention Provision/Risk Management Plan (40 CFR Part 68).
Level of Detail:	

Comments and Rationale:

This information was inadvertently omitted from RFI 51 and is requested in conjunction with that request. This information is necessary for determination of baseline AQ information and for analysis of potential impacts.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 77 – Project Emissions and Regulatory Applicability/Compliance

1. Please provide information on the applicability of New Source Performance Standards (40 CFR 60) and National Emission Standards for Hazardous Air Pollutants (40 CFR 61, 63) that may be subject to the stationary source or equipment used during drilling/construction and operations.

2. The ER did not provide detailed information to determine the applicability of Compliance Monitoring (CAM, 40 CFR 64). CAM requirements apply to stationary sources that are equipped with post-process pollutant control devices, have pre-control device emissions equal to or greater than 100 percent of the major source threshold for a pollutant as defined in 40 CFR Part 70 and Part 71, and are subject to the Title V permit program. If any of the equipment used at the stationary source has a control device, please provide the pre-control device emissions to determine CAM applicability.

3. Will the Project area store any hazardous materials subject to the Chemical Accident Prevention Provision/Risk Management Plan (40 CFR Part 68)?

Date Received: 4/30/10

Date of Partial Response (to Questions 1 and 2): 5/7/10
Date of Response to Question 3: 6/24/10

To: Tim Gallagher HDR Project Manager, Julie McKim USACE

From: Peter Hanley, EIS SPOC

Responses.

Response to No. 1

The stationary emission unit inventory for the drilling/construction and operations phases of the Point Thomson project has not been finalized. The emission unit inventory for the project will be finalized no later than June 30, 2010. ExxonMobil plans to install stationary turbines, engines, boilers, heaters, and incinerators during drilling/construction and operations. Based on the types of emission units planned to be installed and the expected date of construction of each emission unit at Point Thomson, the following New Source Performance Standards (NSPS) may be applicable to the equipment at the stationary source.

- Incinerators: 40 Code of Federal Regulations (CFR) 60 Subpart CCCC – Standards of Performance for Commercial and Industrial Solid Waste Incineration Units for Which Construction is Commenced After November 30, 1999 or Which Modification or Reconstruction is Commenced on or After June 1, 2001

- Engines: 40 CFR 60 Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines

- Turbines: 40 CFR 60 Subpart KKKK – Standards of Performance for Stationary Combustion Turbines

The stationary turbines at Point Thomson will not be subject to National Emission Standards for Hazardous Air Pollutants (NESHAPS) under 40 CFR 63 Subpart YYYY because the stationary source will not be a major source of Hazardous Air Pollutant emissions. The stationary engines at the source will not be subject to the requirements of NESHAPS under 40 CFR 63 Subpart ZZZZ because all stationary engines will be in compliance with 40 CFR 60 Subpart IIII, and therefore will be exempt from the requirements of 40 CFR 63 Subpart ZZZZ.

Response to No. 2

The requirements of 40 CFR 64 do not apply to equipment with emission limitations or standards proposed by EPA after November 15, 1990 pursuant to section 111 (NSPS, 40 CFR 60) or 112 (NESHAPS, 40 CFR 63) of the Clean Air Act (CAA). Equipment at Point Thomson that is subject to 40 CFR 60 Subpart CCCC, IIII, or KKKK is not subject to 40 CFR 64 because the emission standards are pursuant to Section 111 of the CAA and were proposed after November 15, 1990. All other equipment at Point Thomson will not be subject to 40 CFR 64 because the emission units will not use a control device to achieve compliance with any emission limitation or standard.

Response to No. 3

Based on preliminary design, the Point Thomson project currently includes processes (production/injection pipelines and processing facility) that contain a quantity of methane greater than the threshold amount of 10,000 pounds identified in Title 40 Code of Federal Regulations (CFR) Part 68 – Chemical Accident Provisions.

Other compounds identified in Tables 1 through 4 of 40 CFR Part 68 will also be present at the site; in the preliminary design, these are present in less than threshold quantities. The compounds include ethane, propane, butane, and pentane. The quantities of these compounds may change as process design progresses and will be evaluated for applicability when the design is final. A final 40 CFR 68 applicability determination for any other chemical compounds that are included as part of the process as process design progresses will be made after the final project design is completed. Based on the preliminary design, the Point Thomson project will be required to comply with the applicable provisions of Part 68 on the date the facility begins normal operation of the natural gas processing plant.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI No. 78 – Construction Methods

Information Needed

1. *Description of standard Alaska North Slope construction equipment and methods to be used in the construction of Point Thomson development components (as referenced in Chapter 8 of ExxonMobil's Project Description).*
2. *Temporary construction footprints for all components if different than final components footprints.*

Level of detail

Gravel Roads, ice roads, pads, export and infield pipelines, gravel pit, water lines, dock, airstrip, waste transportation, water source

Date Received 5/12/10

Date of Response: 6/9/10

To: Tim Gallagher HDR Project Manager, Hank Baij USACE

From: Peter Hanley, EIS SPOC

Response

The following general methods and techniques, including equipment types and use of temporary footprints, are proposed for construction of the Project.

1. Ice Pads.

Ice pads will be constructed from ice chips, snow and water. The process begins with surveyors marking the limits of the pad (limits of the permitted areas). Following the surveyors, the crews will prepack the snow with rollagons or other off-road vehicles to compact the snow and enhance the freezing process of the tundra. Water is then spread to form a frozen base upon which to build up the required thickness of ice. Build up will be accomplished by hauling ice chips and or snow in large dump trucks that is harvested from permitted sources with trimmers and loaders to the pad. The ice chips and snow are mixed with water that is hauled to the site by water tanker trucks in layers until the required thickness is achieved.

2. Insulated Ice Pads.

Insulated ice pads, if used, will be constructed from ice chips, snow, water, vapor barrier, insulation panels, and rig mats.

The initial construction process for the insulated ice pads is the same as other ice pads.

Once the ice has reached a thickness of 18 inches a vapor barrier will be placed over the entire pad. After the vapor barrier is installed, 4 inch thick foam insulation mats will be placed and then covered with rig mats.

3. Ice Roads

The process for ice roads (and pipeline work pads) is the same as for the uninsulated ice pads described above. The surveyors mark the limits of the ice road. The crews then prepack the snow. Then they will place water, ice chips and snow to build up the required width and thickness to support construction activities and equipment.

4. Export and Infield Pipelines

The Point Thomson Export export pipeline and the in field gathering lines will be constructed in similar manners. The process begins by first constructing an ice road or work pad to support the pipeline construction equipment.

The first major step in pipeline construction is installation of the Vertical Support Members (VSMs). After the ice road has been progressed to a point that there is a safe working distance between the different crews, the drill point for each VSM with be marked and augers (Watson Air drills) will drill the VSM holes to the specified depth. Plywood covers will be placed over the holes to prevent personnel from inadvertently falling in prior to placing the VSMs into the drilled holes.

The VSMs will be placed along the ice road next to the previously drilled holes using hydraulic forklifts or other mobile lifting equipment (rough terrain hydraulic cranes or side boom tractors). The Horizontal Support Members (HSMs) will be bolted to the pile cap. The assembly will then be place into the drilled holes and set to proper elevation and alignment. Angle iron jigs will be welded to the VSMs to hold the assembly in place until a sand slurry is poured into the annulus and frozen into place. The sand slurry will either be purchased from local pre-approved vendors or produced locally from the Point Thomson gravel mine and hauled in regular mixer tucks. All slurry will be tested to comply with ExxonMobil specifications and approved prior to placement.

Following a specified freeze back time, the HSMs will have the saddle assemblies attached to the upper flange of the beam.

The line pipe will then be placed along the ice road, welded into sections, and placed on wooden dunnage (pipeline skids). The field weld locations will be Non Destructively Examined (NDE'd) or X-Rayed, FBE coated (fusion bonded epoxy) per approved specification and insulated.

The pipeline will then be lifted into the elevated pre-positioned saddles using a combination of sideboom tractors, cranes and loaders.

The pipeline will contain expansion sections or Z-Loops to allow the pipeline to expand and contract during changes in temperatures.

When the export pipeline has been welded into a continuous section that extends from the Point Thomson Central Pad on the East end to the Badami tie-in location to the

West, cleaning and gauging equipment (pigs) will be pushed through the entire length of the pipeline with compressed air to evacuate any debris left behind from the construction process.

The summer after completion of pipeline construction, hydrotesting equipment will be transported via barge to both Badami and Point Thomson. At Badami, a pump will be set-up at the reservoir and a fast-line or hose will be run along the toe of the road from the reservoir to the end of the export pipeline, the line/hose will be connected to a temporary tank, and another pump will be located between the tank and the export pipeline. A test trailer will be set-up at Badami to monitor, record, and document the hydrotest. Water will be drawn through this system at Badami and the air will be displaced from the export pipeline by a displacement pig pushed by the water. Once the pipeline is filled and the temperature stabilized, a high pressure pump will pressure up the pipeline and will hold at the desired pressure for at least 8 continuous hours. Once the hydrotest is complete, an air compressor at Badami will push pigs to displace the water to Point Thomson where water settling tanks and carbon bed filters will be set-up. The water will be discharged to the tundra after passing through the water tanks and carbon beds to meet the discharge requirements of the General NPDES permit. If unable to meet the discharge permit standards, the hydrotest water will be displaced to tanker trucks at Point Thomson where it will be transported to a Prudhoe Bay or other disposal well.

At the completion of dewatering the pipeline, air compressors and dehydration equipment at Badami will dry the line to the project's dryness specification. Once the pipeline is dry, nitrogen will be pumped from Badami towards Point Thomson to fill with nitrogen to leave the pipeline inerted until start-up.

The infield pipelines will be constructed in a similar manner to the export pipeline.

Final clean up and inspection of ice roads will be conducted following construction and again during the following summer.

5. Mine Site Development

Prior to any work taking place the permitted limits will be surveyed and staked. The organic overburden layer will be removed using trimmers. The overburden will be pushed into piles and then loaded and hauled to the ice pad for storage. The inorganic overburden will be removed by the drill and shoot method. Air track drills will be used to drill the overburden after which the holes will be loaded with AN/FO (blasting agent) and the overburden will be shot. Dozers will push the overburden into piles and then it will be loaded and hauled to another ice pad for storage. The gravel will then be mined and removed by the same drill and shoot method.

During the blasting, each hole will contain approximately 100 pounds of AN/FO, a detonator and primer, tied into a network of boosters and surface relays. Each shot will contain approximately 325 holes and will yield approximately 21,000 cubic yards (65 cubic yards per hole). This work will be performed on a double shift basis, with loading and shooting occurring at the end of each shift.

After all of the gravel for the project has been removed from the mine site, the

overburden with be placed back into the pit per the mine site rehabilitation plan drawings and the stream diversion installed. The fresh water intake pipe will be installed into the mine site for use once the mine site fills up with water.

6. Gravel Roads & Pads

Prior to any work taking place the permitted limits of the gravel roads and pads will be surveyed and staked. Next all snow in excess of 4" in depth will be removed from the footprint of the road or pad and the gravel placement will commence. The gravel will be hauled in "B-70" haul units to the fill site and dumped. The B-70 haul units have a 70 ton articulated belly dump that allows them to operate within the permitted footprint. A fill dozer will then spread the material within the permitted footprint in one foot lifts. Each lift will be compacted with a minimum of five passes using a 10 ton vibratory roller traveling at less than 5 miles per hour. Traffic will be routed over the fill area to aid in the compaction effort. This activity will continue until the final elevation is achieved.

7. On-Shore Barge Abutment

Prior to any work taking place, the permitted limits of the abutment will be surveyed and staked. The surveyors will then survey and stake the bulkhead area and establish the starting point. Templates will be placed with a Manitowoc 999 crane and pin piles will be driven in the pockets on the template to prevent the template from moving while the sheet pile are being driven. Thermal modification of the soil will be necessary and this will be accomplished with a boiler unit and steam probes placed in pilot holes to thaw the soil where the sheets will be driven. The sheet pile will be lifted and placed against the template and stabbed into the ground. The sheet and anchor pile will be driven to the specified depth using an APE 200-6 vibratory hammer. Gravel fill will be placed around the sheet pile cells inside the bulkhead in a uniform manner to prevent distortion of the bulkhead. The fill will be placed in level lifts across the entire cell area, and the elevation of the fill between adjacent cells will not differ by more than three feet. The winter placed fill will be compacted with a 10 ton vibratory roller with the exception of the areas within five feet of the open cell bulkhead, which will be compacted with smaller hand compactors. Sheet pile cut-off and welding will occur after the summer compaction is complete in this area.

8. Dolphin Installation

Four barge dolphin consisting of 3 piles each will be placed in the water to assist in the barging effort. The 1st will be 150' from the dock face, and the 2nd will be 250' from the first. The remaining 2 will be placed at 400' intervals from the 2nd dolphin. The sea ice will be thickened and grounded around each location to keep the water out once the ice is cut. After the ice is grounded, it will be cut and removed from the dolphin location and stockpiled on the sea ice. The 3 piles for each dolphin will then be driven utilizing a Diesel Impact Hammer, the piles cut off to grade, and the pile cap installed tying all 3 piles together. Additionally the pile cap has a rubber fender for the barge to rest against and a bollard for tying the barge off to the dolphin.

9. Water Line

The water line between the new water source (gravel mine) and Central Pad will be a 4 inch diameter HDPE pipeline. It will be insulated with 4 inches of insulation yielding an

outside diameter of 12 inches. It will be installed on 12 x 12 timber supports, each 10 feet long and placed approximately 20 feet apart.

An ice road / working pad will be constructed adjacent to the water line route for the water line installation. The insulated HDPE water line will be fusion bond welded together using a McElroy TracStar pipe fusion machine. The pipe will be placed into the machine where it is bonded together. The bonded section will then be pulled ahead and the next joint added on. This process will continue until approximately a 1,000 feet pipe string has been welded and pulled out at which time the welding machine will move forward to the end of the pipe string and continue the process again. Once the next 1,000 feet pipe string is complete the two strings will be welded together. This will continue until the entire pipe has been welded together for the water line. All of the weld joint connections will be insulated with insulation kits and the line complete. The line will then be lifted into place on 12 x 12 timber supports place on the tundra and anchored down to the timber supports.

10. Airstrip

Construction of the gravel airstrip will be done in the winter in a manner similar to the gravel roads and pads. After the gravel has been placed for the airstrip, the piling for the navigational aides, approach lighting, and buildings will be installed. The piling hole will be drilled with a Watson drill. The pile will be placed in the hole, surveyed for proper alignment and elevation, and then sand slurried in place. Once proper freeze back of the sand slurry is achieved, the navigational aides, approach lights, and building will be set on the piles. The areas for approach lights will require an ice road to be constructed prior the pile installation. This ice road will also be used for the installation of the power cable and the lights. After breakup and the gravel has been conditioned and compacted, the power cables will be trenched into the gravel for the remaining facilities and the runway and threshold lights will be installed.

11. Waste Transportation

Refer to the response to RFI 67 – G&I Facility and RFI 69 - UIC Well.

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 84 – Logistics for Construction, Monitoring and Training Efforts

Date Received: July 1, 2010

Response Date Requested: July 9, 2010; Date of Response: July 28, 2010

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Information Needed:

What types of ongoing or regularly scheduled activities might occur throughout the life of the project that would require additional transportation of people and equipment not covered in the preliminary logistics plan?

Level of Detail

Frequency of monitoring trips, expected flight paths, additional infrastructure needs, and types of helicopters/planes/boats/ for the following (see response below):

Response:

1. *Crews and materials to the East, West pads from the Central pad for construction activities (and drilling and operations).*

A representative crew and equipment complement for initial construction of the East and West pads is shown in the Table 1. This level of activity would only be required during one construction season.

Table 1 - Representative Equipment List and Work Team
PTP Civil Infrastructure at East and West Pads

A representative crew and equipment complement for initial construction of the East and West pads is shown in the Table 1. This level of activity would only be required during one construction season.

Equipment	
988 Loader	2
D-10 Dozer	2
D-9 Dozer	1
Hitachi 1600 Shovel Loader	0
B-70 Dump Trucks	13
16G Motor Grader	2

Pickup	4
Compactor	1
Estimated Direct Equipment Cost for Task	
Personnel	
Operator Foreman	1
Teamster (truck driver)	13
Operator	8
Laborer	2

Pad maintenance at the East and West pads, the Airstrip, and the associated infield roads on an ongoing basis would typically involve a grader and compactor and would be done weekly or as needed during the summer season to maintain integrity. In addition, a snow blower and grader would operate as needed (estimated at approximately 31 days) to remove snow during the winter.

Significant logistical support will be required for drilling at the East & West Pads.

2. Environmental compliance monitoring: How would frequencies change seasonally and for different fauna?

Environmental compliance monitoring requirements are generally dictated by the conditions of the specific permits and are unknown at this time. Consequently, it is not possible to identify the specific programs, species, frequencies, etc.

3. Pipeline monitoring: Section 5.5, Production Gathering Lines, of the ExxonMobil's Project Description states that "Visual inspection of gathering lines will typically be performed on a weekly basis via aerial surveillance… or by ground-based operations". How often is it anticipated that this would be done aerially? Would this be done through road access during the ice road season and by air other times of the year? Please provide more details.

Export and infield gathering lines that are not in close proximity to roads will be monitored on a weekly basis using fixed wing or helicopters. In most cases, the aerial surveillance will occur on a year-round basis. The exception to this might be times when it is necessary or desirable to conduct on-the-ground inspections using off-road vehicles or ice roads in close proximity to the roads or pads. Such ground based inspections would not be expected to occur more than 1 or 2 times a year. To the extent feasible, the aerial surveys will be conducted as part of other regularly scheduled air travel to/from the Central Pad.

4. Spill response training: Frequency and types of boats and other equipment that will be mobilized.

Specific spill response training drills have not been designed. We would expect to conduct two deployment drills each August, one drill for each shift.

The drills will likely consist of a scenario where oil is leaked into the surrounding water. The Point Thomson Spill Response Team will mobilize and deploy on site resources, i.e. fastanks for storage and shore seal boom for containment. Two work boats will deploy containment boom. A skimming vessel located at West Dock or Central Pad may be deployed to recover the oil.

The drill will like involve onsite and offsite personnel, e.g., personnel from Point Thomson might be on the water deploying boom and on land setting up storage and shore seal boom. Additional personnel from West Dock deploying would be mobilized with an additional skimming system.

The drill may also include setting up a decontamination area for personnel and additional helicopter transportation.

5. Any other regularly scheduled monitoring efforts.

There will be numerous regularly scheduled monitoring efforts to support ongoing operations and compliance efforts. These will generally be performed by personnel that are based at the Project's facilities, however, and will not require specific or extra transportation to/from the Project area.

(continued on back side)

Information Needed:	1. Please provide the worst case release of "product" (defined as liquids that may include produced water, crude oil, gas condensate, etc.) from each of the gathering lines (East Pad to Central Pad and West Pad to Central Pad) as well as for the Export line from Central Pad to Badami. The worst case for each line should assume: • Complete and instantaneous break of the pipeline • Normal time for the SCADA system to shut down the valves along the line to isolate the break (with that time frame specified), after the break occurs • Passive drainage from the pipeline after valves are shut down, considering elevation changes in the pipeline that would prevent complete loss of fluid (if that is appropriate) • Summer conditions, when oil does not cool as quickly as in winter • All oil is lost before any containment can be mobilized and implemented • ExxonMobil's best estimate of the location of valves, elevations of the pipelines, and other features that may affect the amount of oil released (considering all presently proposed alternatives) • ExxonMobil's best estimate of the maximum volume of fluids that could be in the pipeline at the time of a break. 2. Please also provide the maximum volume of product that could be lost from a pipeline at or near the East and West Pads and the Central Pad for all alternatives.
Level of Detail:	Immediate priority is the estimate for each pipeline in gallons or barrels of fluid potentially lost following an instantaneous break. Provide the specific backup for the calculations so that an outside party could repeat the calculations if necessary. This backup can be provided as a secondary priority.

Comments and Rationale:

ExxonMobil has provided a worst case scenario for an blowout oil spill in their October 2008 version of the ODPCP. However there is no description for the worst case spill that could occur from the gathering lines or the export line. This is relevant because it sets a boundary for the largest spill that could occur (even if the likelihood is extremely low that it will occur). Also, given the current public climate regarding oil spill risk analyses, I believe we need to be explicit about the worst case as we see it.

I do not find a detailed elevation diagram for the 2 gathering lines or the export line so it is not practical for me to try to estimate the amount of oil that could be released, given info about the location of shut off valves, elevation changes that would slow or prevent passive drainage, or other factors that could limit the volume spilled in the event of a complete break in one of those lines. It seems unlikely that all the oil in 22+ miles of the export pipeline could be released but that would have to be the hypothetical worst case unless I have a better estimate.

Level of Priority:	☐ Low	☐ Standard	☒ High	☐ Extreme
Time Sensitivity:	☐ Low	☐ Standard	☒ High

Response to Request for Information

RFI 91 – Maximum Oil Spill Possible from Gathering Lines and from Export Line

Date Received: June 26, 2010

Response Date Requested: July 2, 2010; Date of Response: July 28, 2010

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Information Needed:

1. *Please provide the worst case release of "product" (defined as liquids that may include produced water, crude oil, gas condensate, etc.) from each of the gathering lines (East Pad to Central Pad and West Pad to Central Pad) as well as for the Export line from Central Pad to Badami.*

   The worst case for each line should assume:

   - *Complete and instantaneous break of the pipeline*
   - *Normal time for the SCADA system to shut down the valves along the line to isolate the break (with that time frame specified), after the break occurs*
   - *Passive drainage from the pipeline after valves are shut down, considering elevation changes in the pipeline that would prevent complete loss of fluid (if that is appropriate)*
   - *Summer conditions, when oil does not cool as quickly as in winter*
   - *All oil is lost before any containment can be mobilized and implemented*
   - *ExxonMobil's best estimate of the location of valves, elevations of the pipelines, and other features that may affect the amount of oil released.*
   - *ExxonMobil's best estimate of the maximum volume of fluids that could be in the pipeline at the time of a break.*

2. *Please also provide the maximum volume of product that could be lost from a pipeline at or near the East and West Pads and the Central Pad for all alternatives.*

Response:

1. An assessment of the pipelines was conducted to determine approximate liquids release volumes.

A. Export Pipeline Applicant's Base Case (same as Alternative 4)

The potential release volumes from the export pipeline as currently design (base case) were calculated assuming:

- Complete and instantaneous break of the pipeline (guillotine failure)
- Estimated time for leak detection system to indicate alarm of 30 minutes plus an estimated time shut down the system of 15 minutes
- Passive drainage from the pipeline after the system is shut down, considering elevation changes in the pipeline that would prevent complete loss of fluid
- Summer conditions
- All oil is lost before any containment can be mobilized and implemented
- Export pipeline will be installed on VSM with 7 ft clearance to tundra surface.

Best estimate of the maximum volume of fluids in the pipeline at the time of a break were also calculated.

Potential release volumes were calculated using the following formula:

$$Release\ volume = L \times C + FR \times (TD + TSD)$$

where:

C is the pipeline capacity per foot (0.14 barrels per foot for a 12.75 inch diameter line with a wall thickness of 0.406 inches);
FR is the design flow rate (while the export pipeline design flow rate is 10,000 barrels per day, a value of 12,000 barrels per day was used in the calculations to account for the possibility of fluctuations in production rate);
L is the segment length between hydraulic break points in feet;
TD is the estimated time to detect the break (30 minutes based on standard North Slope practices); and
TSD is the estimated time from detection to system shut down (15 minutes based on standard North Slope practice).

Results of the release volume calculations are presented in the following table.

Feature	Segment Length [ft]	(L - H) × C [bbl]	FR x (TD + TSD) [bbl]	Release Volume [bbl]
Central Pad	1,800	252	375	627
"C" Creek	5,500	770	375	1,145
"D" Creek	5,300	742	375	1,117
"E" Creek & Creek 18A	6,800	952	375	1,327
	4,500	630	375	1,005
"F" & "G" Creeks	12,200	1,708	375	2,083
"H" & "I" Creeks	12,200	1,708	375	2,083
"J" Creek	2,900	406	375	781
"K" Creek	13,000	1,820	375	2,195
"L" Creek	4,700	658	375	1,033
	5,100	714	375	1,089
"M" Creek	3,600	504	375	879
"N" Creek	3,900	546	375	921
	2,800	392	375	767
	2,350	329	375	704
"O" Creek	10,500	1,470	375	1,845
East Badami Creek	2,550	357	375	732
Middle Badami Creek	5,300	742	375	1,117
West Badami Creek	2,900	406	375	781
	5,200	728	375	1,103
Badami	3,800	532	375	907
Maximum Release Volume		1,820	375	2,195

The total length of the export pipeline is approximately 22.1 miles or 116,700 feet and has a total volume of approximately 16,400 barrels.

Calculations for Alternatives 3A and 3B cannot be completed without detailed alignment profile information. Calculations were not completed for buried cases based on lack of design definition.

B. East and West Gathering Pipelines

The potential release volumes for the east and west gathering pipelines as currently designed (base case) were calculated assuming:

- Complete and instantaneous break of the pipeline (guillotine failure)
- Estimated time for leak detection system to indicate alarm of 30 minutes plus an estimated time shut down the system of 15 minutes
- Contents in gas phase resulting in complete evacuation of the lines and discharge of entire equivalent liquid volume
- Summer conditions
- Shut-in conditions
- All oil is lost before any containment can be mobilized and implemented
- Both East and West Gathering pipelines will be installed on VSM with 7 ft

clearance to tundra surface.

Potential release volumes were calculated using the following formula:

$$Release\ volume = L \times C \times \frac{P_1 \times T_2}{T_1 \times P_2} \times \frac{FR}{GR} + FR \times (TD + TSD)$$

where:

C is the pipeline capacity per foot (0.27 cubic feet per foot for an 8.625 inch diameter line with a wall thickness of 0.812 inches);
FR is the design liquid flow rate (while the export pipeline design flow rate is 10,000 barrels per day, a value of 12,000 barrels per day was used in the gathering lines calculations to account for the possibility of fluctuations in fluid composition within the gathering pipelines that might result in a greater equivalent liquid content for brief periods of time);
GR is the design gas flow rate of the pipeline (200 million standard cubic feet per day);
L is the pipeline length in feet;
P_1 is the internal design pressure of the pipeline (8,815 psia);
P_2 is atmospheric pressure at standard conditions (15 psia);
T_1 is the fluid temperature (544.7°R equal to 85°F);
T_2 is the temperature at standard conditions (527.7°R equal to 68°F);
TD is the estimated time to detect the break (30 minutes based on standard North Slope practices); and
TSD is the estimated time from detection to system shut down (15 minutes based on standard North Slope practice).

<u>East and West Gathering Pipelines Applicant's Base Case (same as Alternative 4)</u>

The East Gathering Pipeline is approximately 25,700 feet in length (4.9 miles) with a total volume of 6,939 cubic feet. Converting this volume from shut-in conditions to standard conditions yields a total volume of gas of approximately 4.0 million standard cubic feet. Multiplying this volume by the ratio of 12,000 barrels per 200 million standard cubic feet yields an equivalent liquid content of 237 barrels. Adding the volume that would potentially enter the line in the assumed 45 minutes between rupture and system shut down of 375 barrels, yields a maximum equivalent volume if liquids that might be lost of 612 barrel.

Similar calculations for the West Gathering Pipeline with an approximate length of 25,300 feet (4.8 miles), yields a maximum equivalent volume of liquids of 609 barrels.

<u>East and West Gathering Pipelines Alternative 3A and 3B</u>

Lengths of proposed gathering line alignments for Alternative 3A and 3B can only be roughly approximated (~6 and 4 miles for the East Gathering Line and ~6 and 4 miles

for the West, for Alternatives 3A and 3B, respectively); therefore potential release volumes cannot be calculated with the same level of certainty as for the current base case design. However, based on these approximate lengths the potential liquids release volume for the alternative alignments of the East Gathering Pipeline would be roughly 667 barrels and 570 barrels for Alternatives 3A and 3B, respectively. While the potential liquids release volume for the West Gathering Pipeline would be roughly 570 barrels and 667 barrels for Alternatives 3A and 3B, respectively.

The proposed alternatives also would add approximately 2 miles of gathering line between the Central Well Pad and the relocated Central Processing Facility, which would have a potential liquids release volume of 472 barrels.

The proposed alternatives would also add approximately 2 miles of re-injection pipeline between the relocated Central Processing Facility and the Central Well Pad. However, this re-injection pipeline will be gas line with no liquid equivalent. Therefore no spill volume calculation is needed.

Calculations were not completed for the buried cases based on lack of design definition.

2. The maximum volume of liquids that could be lost at or near the East Pad, West Pad, and Central Pad were also calculated.

East Pad

The calculated maximum liquids release volume at the East Pad is 612 barrels for the applicant's base case and Alternative 4, roughly 667 barrels for Alternative 3A, and roughly 570 barrels for Alternative 3B.

West Pad

The calculated maximum liquids release volume at the West Pad is 609 barrels for the applicant's base case and Alternative 4, roughly 570 barrels for Alternative 3A, and roughly 667 barrels for Alternative 3B.

Central Pad

The calculated maximum liquids release volume at the Central Pad is 627 barrels for the applicant's export pipeline base case and Alternative 4. As stated above, the potential liquids release volume cannot be calculated for the export pipeline alternative due to the lack of alignment profile information.

The maximum potential liquids release at the Central Pad from either the East or West Gathering Pipeline is approximately 612 barrels for the applicant's base case and Alternative 4, and approximately 667 barrels for Alternatives 3A or 3B.

POINT THOMSON PROJECT EIS

Memo

To:	Michael Allwright		
From:	Peak Oilfield Service Company	Project:	Point Thomson Project EIS
CC:		Subject:	RFI 93
Date:	July 14, 2010	Job No:	123515

1. What alternatives are available for the following components and what are each of their optimal uses, advantages, and limitations:

a. Feasibility of using ice pads for well pads during operations

Utilizing ice pads for well pads during operations is feasible to some extent; however it is not standard practice on the North Slope.

Positives for using ice pads
In General constructing ice pads has less environmental impact than constructing a gravel pad.
The ice pad can be constructed in different locations each year as different areas of the pad are needed.
The initial construction may be cheaper depending on the thickness of the pad required.

Negatives for using ice pads
Depending on how many years a pad needs to be constructed, the cost can be more than installing gravel one time.
There could be a requirement after a couple of years to move where the ice pad is constructed to give the tundra a chance to recover. This is fairly typical as ice road alignments are often moved over the width of the road from previous years to allow for the tundra to recover.
If ice pads have to be constructed each year they could be subject to changes in environmental regulations, where as if gravel were installed up front the pad would be in place.
There would be no access to the pad over the summer unless an over summer pad were constructed.
Constructing multiyear over summer pads may have some adverse effects to the tundra causing damage.

Assuming ice pads were to be used in conjunction with gravel pads for the wells and well houses, the ice pads would have to be constructed to the same elevation of the gravel if drilling were to be from the ice pads. If drilling would be from the gravel, and the ice pad were for storage, ice pads may not be needed unless there were two rigs on the gravel pad. If over summer ice pads are planned, care should be taken when placing the insulation and rig mats. Each year the pads will require maintenance, ie the insulation will need to be removed, the pad brought back up to grade, holes filled and outer perimeter reconstructed. (see RFI 72 regarding insulated ice pads).

Generally speaking, ice pads are used for winter exploration activities when it is unknown if a field will go into production, or when additional pad space is needed during active winter seasons. Once a field goes into production, utilizing the gravel pads and roads provides better access year round for continuous operations.

Insulated ice pads are typically constructed when an exploration program is a multiyear program and are constructed to eliminate multiple mobilizations to the project.

b. Light-duty gravel roads

Constructing light duty gravel roads is feasible and would result in a lower initial per mile cost. Typically a light duty road would be constructed to a pad where there was no need for heavy loads.

There are several drawbacks to light duty roads. Light duty roads have less fill and may be narrower than a standard North Slope road. As a result, placing culverts in the road to allow for water flow and runoff becomes a problem. There is only a small amount of material placed over the culverts, which reduces the capacity of the culverts.

When discussing light duty gravel roads for access to drilling pads there are a number of drawbacks to the light duty road vs standard road, the greatest of which is the fact that heavy loads can't drive on the road. This severely limits drilling at the drill sites to only during the winter season and an ice road must still be constructed each year to access the pad with a drill rig and for drilling support equipment. This can extend the time it takes to complete the wells on the pad by many years, or would require an additional rig on site. In the event of a problem at the well during the summer, there would be no way to move equipment to the well site to respond.

Light duty roads may also require more maintenance than a regular duty road.

The difference between the environmental impact of a light duty road vs a standard road seems to be very little. In either case there is a gravel road across the tundra. An extra few feet of fill and five or ten feet of width doesn't seem like it would create a much larger impact. If the intent is to drill year round a standard North Slope would make more sense than a light duty road.

c. Reduced-length airstrip with seasonal ice component

Constructing a reduced length airstrip with an ice component is feasible. Utilizing a reduced length airstrip could be practical if large aircraft support is only needed during the winter when the ice component of the airstrip is constructed.

The advantages to the reduced length airstrip is that there is less lasting environmental impact, and if the ice component is only needed certain years it may be less expensive to construct.

The disadvantages to constructing a reduced length airstrip are the limited access to the site for large aircraft during breakup, summer and fall, until the airstrip extension is complete. The schedule for completing an extension is weather dependent every year. A gravel road or an ice road would need to be constructed to the water source lakes. Water and ice volumes would have

to be permitted for the duration of the project and would have to be available in adequate quantities. At times there are warming trends in the winter where the temperatures can reach freezing or above. This could limit the use of the ice extension. The electrical systems and lights for the ice airstrip would probably be temporary and would need to be able to interface with the permanent lights for the gravel runway. Utilizing temporary lights with electrical wires run along the edge of the airstrip can create additional maintenance and can cause tripping hazards. Another factor to consider is that if an ice pad or ice road has been constructed in the same place for a number of years, the agencies may request that the road or pad be moved slightly to give that tundra a chance to recover. In the case where an airstrip extension is constructed, moving the ice extension might not be an option. As a result there is a possibility that the extension could not be built in some years, or if the pad is not moved there is the potential for permanent damage. If there is permanent damage a the extension might as well have been constructed from gravel.

If the purpose of the airstrip is to allow for heavy aircraft support when Point Thomson does not have other means of support, ie ice road or barges, then a reduced length airstrip with the seasonal extension does not make sense. If the requirement for heavy aircraft support is only during the winter, and for a short number of seasons, the reduced length option could make sense. Another consideration is the need to be able to support heavy aircraft in the event that another area on the slope needs assistance (a example could be assisting another company or village with spill cleanup equipment or material).

d. Descriptions of construction efforts for ice airstrip extension, ice airstrip on freshwater body (lake), and ice strip on sea ice.

Construction of an ice airstrip on the tundra is similar to constructing an ice pad or ice road. The existing snow is packed down and then ice aggregate (chips) are saturated with water and spread out where the runway is staked. If an airstrip is all ice, it is typically constructed to six inches in thickness. During the summer months a location for the airstrip would have been found that is mostly flat. If the area for the strip is not flat it will take considerably more time and resources to construct.

In the case of an airstrip extension, the same techniques are utilized; however the ice is built up in six inch lifts until it is level with the existing gravel airstrip.

Ice airstrips on lakes or sea ice have different construction methods depending on the design parameters for the airstrip and on the depth of water in the lake or sea. If the airstrip to be constructed is in water deep enough that the airstrip is floating, then pumping units can be used to free flood the area for the airstrip. This continues until the ice is to the design thickness. If it is a sea ice airstrip the surface is capped with freshwater. If the airstrip is planned on ice that is not grounded, but that will ground out when the airstrip is constructed to the designed thickness, construction starts with pumping units and when the pumping units can no longer pump, the construction techniques switch to conventional ice road and pad construction, which is used to finish grounding out the airstrip. In the event that an airstrip is planned to be constructed on an area where part of the airstrip is floating and part of it is grounded, the airstrip must be designed with this in mind and extra care must be taken during construction and use of the strip.

e. Feasibility of placing pipelines in roads (infield or and export lines).

This is not Peak's area of expertise. The question should be posed to an engineering company that designs pipelines or a contractor with experience installing pipelines.

2. What maintenance is required for both full size and light-duty gravel roads, and gravel airstrips in winter on the North Slope? Plowing, sanding?

Maintenance of gravel roads on the North Slope is similar to any gravel road. Pot holes and washboard develop over time depending on the amount of use. On the North Slope the spring breakup is typically the worst. Utilizing a motor grader to flatten the rough areas is a common maintenance practice. Depending on the severity of the potholes, rough sections or washout of roads, hauling additional gravel or surface course may be required. The other part of summer maintenance includes dust control. This is achieved by watering the gravel roads.

In the winter the majority of gravel road maintenance consists of clearing snow from the roads and pads when it is snowing or the wind is blowing enough to move the snow. On the roads and on open pads this is achieved with a motor grader and snow blower. The motor grader uses its blade to make a windrow down the middle of the road. The snow blower follows behind the motor grader and blows the snow away. On pads, where there are obstructions a loader may be used to remove snow from around the obstructions and to pile it where it can be blown away. The other general practice for removing snow from pads is to push it off the pad onto the tundra. Care must be taken to not push any gravel with the snow onto the tundra. When developing a snow removal plan the prevailing wind must be taken into account when deciding where snow piles can be placed and how the snow will be pushed there. As snow piles build up over the course of the winter, the piles are kept smooth with no berms and with relatively low slopes to prevent drifting. This is achieved with a dozer.

Gravel roads with no nearby obstructions tend to drift less than ice roads because they are elevated from the tundra, where as ice roads typically only have six inches of fill. If pads are constructed in areas where drifting snow is a problem, snow fences can be constructed away from the pads. The snow fences collect the snow and reduce some of the maintenance costs associated with clearing snow from pads.

The other winter maintenance that can take place is to water the roads. This serves two purposes. The first purpose is that as the water freezes it fills in any washboard or potholes and creates a smooth surface for driving. The second purpose is that it keeps the gravel frozen in to the road so that when the motor grader and snow blower clear snow the gravel is not scraped up and blown off.

(continued on back side)

Information Needed:	• Data or substantive text discussing the likelihood that the oil rim will be viable for production. Please also define "viable" and the threshold at which the oil rim becomes viable. • The Applicant's anticipated date/target year when viability of oil rim will be known • If the oil rim is not viable, how, if at all, will the Applicant use the East and West pads. Is there any possibility that ExxonMobil would abandon or demobilize East and West Pads as part of this project if the oil rim is not viable for oil rim production? • If the oil rim is not viable, would the infield pipelines still be constructed as part of this project (for instance as part of gas cycling and condensate recovery)? If not, would infield pipeline construction then be envisioned as part of a future gas production project (reasonably forseeable future action)?
Level of Detail:	Text, graphs, or data that will allow the EIS team to adequately describe the anticipated oil rim and gas reservoir delineation efforts at the East and West pads and the anticipated activities should the oil rim be determined not viable. Response should include any changes to infrastructure (roads, kinds of pipelines required, facilities changes) that would be required if East and West pads are used to produce hydrate instead of oil as part of the currently proposed project.

Comments and Rationale:

The Applicant's Project Description for Alternative 2 notes that

> Wells drilled from the East and West Pads would be designed to penetrate and evaluate the oil rim to determine if production from the oil rim is viable. If the oil rim is determined to be viable, the infield gathering pipelines would connect the East and West Pads to the Central Processing Pad, and would deliver the produced hydrocarbon stream to the Central Processing Facility (CPF). (1-4 para. 3)

This wording seems to imply that the need for infield gathering pipelines is contingent upon the viability of the oil rim. On page 3-2 of the Project Description, the wells are described as being

> Designed to penetrate the oil rim. This zone will be evaluated, sampled, and tested, as appropriate. If production from the oil rim is viable, the well(s) will be tied into the CPF. Producing these wells would allow additional dynamic reservoir performance data to be collected across the eastern or western portions of the field and they could be used for subsequent development activity.

Again, the wells themselves are assumed necessary for exploration and testing of the resource, but the tie-in is contingent upon the viability of oil rim production.

Understanding when the Applicant expects to know whether the oil rim will be viable, and whether the project will use East and West Pads for condensate production and therefore require infield gathering lines or whether the pads will not be used and not require gathering lines, will allow the Alternatives team to understand better the Applicant's anticipated facility needs. The additional understanding will also enable us to accurately evaluate the benefits and deficits of full gravel-pad build vs. gravel/ice-pad construction for development of Alternatives.

Level of Priority:	☐ Low	☒ Standard	☐ High	☐ Extreme
Time Sensitivity:	☐ Low	☐ Standard	☒ High	

ExxonMobil Point Thomson Project
Response to Request for Information

RFI 95 – Contingency for Infrastructure if Oil Rim is Nonviable

Date Received: July 1, 2010

Response Date Requested: July 7, 2010; Date of Response: August 27, 2010

To: Tim Gallagher HDR Project Manager

From: Peter Hanley, EIS SPOC

Information Needed:

- *Data or substantive text discussing the likelihood that the oil rim will be viable for production. Please also define "viable" and the threshold at which the oil rim becomes viable.*
- *The Applicant's anticipated date/target year when viability of oil rim will be known*
- *If the oil rim is not viable, how, if at all, will the Applicant use the East and West pads. Is there any possibility that ExxonMobil would abandon or demobilize East and West Pads as part of this project if the oil rim is not viable for oil rim production?*
- *If the oil rim is not viable, would the infield pipelines still be constructed as part of this project (for instance as part of gas cycling and condensate recovery)?*
- *If not, would infield pipeline construction then be envisioned as part of a future gas production project (reasonably forseeable future action)?*

Level of Detail

Text, graphs, or data that will allow the EIS team to adequately describe the anticipated oil rim and gas reservoir delineation efforts at the East and West pads and the anticipated activities should the oil rim be determined not viable. Response should include any changes to infrastructure (roads, kinds of pipelines required, facilities changes) that would be required if East and West pads are used to produce hydrate instead of oil as part of the currently proposed project.

Response:

Wells drilled from the East and West pads will provide additional information about the reservoir, including the oil rim to the extent encountered. The value of this information has been explained in RFI 52- Natural Gas Production and ExxonMobil comments on Purpose and Need.

If the well data warrants further evaluation with regard to oil rim viability, the initial East and West Pad wells could be tied-in to gain long term production information to further assess oil rim viability. Timing for gathering line installation would be after drilling of the East and West pad wells is completed and well test data indicates the oil rim may be viable. This would be after the Central Processing Facility is commissioned.

If the oil rim is not viable or the well encounters a developable gas interval, the East and West Pad wells could be sidetracked or completed to access gas cap resources. In this case, the gathering lines may be installed to cycle gas to test reservoir connectivity and evaluate condensate recovery. The gathering lines could also provide service for gas production and/or expanded cycling.

As discussed in RFI-52, the East and West Pads are integral not only for an initial determination of oil rim viability but also are strategically located to support expected future gas production wells.

RFI 106 – Dredged Materials Disposal Location

Date Received: April 7, 2011

Date of Response: April 29, 2011

To: Tim Gallagher and Michael Allwright, HDR and Hank Baij, USACE

From: Steve Calder, ExxonMobil

Information Needed:

Provide a specific location for placement and disposal of dredged materials.
Provide the basis for selection of the disposal site and evidence that the disposal location avoids and minimizes impacts to coastal resources.

Level of Detail

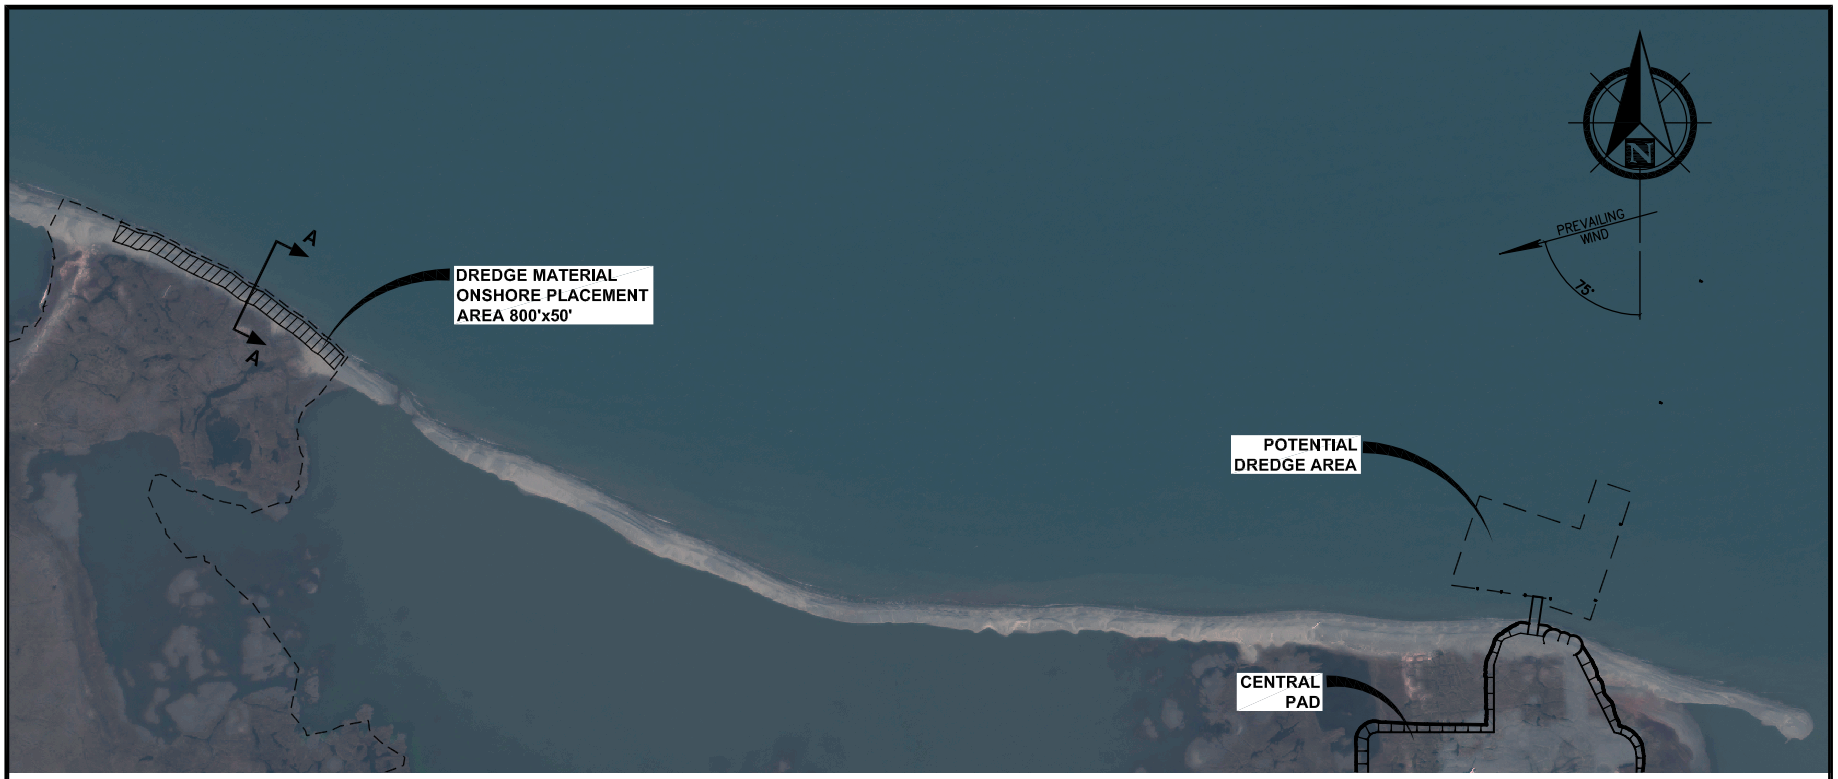
Please provide GIS data specifically identifying the dredged material disposal site.
Discuss the basis for selection of the disposal site. Include geotechnical borehole data from the dredging area and the results of chemical and physical testing of materials at both the dredging and disposal sites.

Please discuss the pros and cons for of the placement and use of dredged materials in alternative locations.

Response:

Location and Rationale for the Placement of Dredged Spoils

The dredged material will be placed on the mainland coast above Mean High Water on a stretch of beach approximately 3/4 miles west of the area to be dredged. The spoils would be placed within an area 50 feet wide by 800 feet long (see attached Figure 20-5A). The composition of beach material in this area is typical non-vegetated sand/gravel lens overlying a tundra base (also characterized as a "chenier" beach).



The primary considerations for selecting this location are:

- The selected location is far enough away from the barge offloading area so that a westerly storm would not refill the dredged area.
- Historically, westerly storms have occurred less often than easterly storms so locating the spoils on the west side of the area to be dredged is preferred.

- The proposed placement site is in a relatively stable location even though active sediment transport does occur in the area. Specifically, the spit to the west of the spoils placement area and the spit to the east of the dredge area have been forming and retracting over the last 50 years based on a review of available data. Given such conditions, the dredge spoils are expected, over time, to contribute a small amount of material to the formation of these local sand spits.

Subject: Sampling/testing of sediments at Point Thomson - data available (UNCLASSIFIED)

Classification: UNCLASSIFIED
Caveats: NONE

Hi Steve,

Unless there have been any incidents of fuels, chemicals, solid materials, etc., spilled or discharged into the marine waters and sediments, I do not have a strong reason to believe there is contamination at the barge landing facility at Point Thomson. I understood Exxon Mobil was planning to test the sediments to confirm no sediment contamination and gather background data for future use, not knowing this had been done previously. You might check with Javier. I noted the request for testing in the RFI. I did hear sediment core sampling for engineering purposes (physical properties for dredging, pile supports, etc.) had been completed, assuming it was recent for the engineering plans.

If I have the sediment quality data in our old (2003) file, I am unaware of it. So, please send it all to me. It may be sufficient so further testing is unnecessary. I will have a look at it with one of the contractor SMEs.
After that, I can tell you whether sediment sampling will be necessary for the Guidelines (404(b)(1). Someone needs to contact the State DEC to see if they have marine sediment standards established yet.

Since we just spoke on the phone, I recommend you summarize the types of activities Exxon Mobil has conducted at the marine barge landing area to date. This will establish the presence/absence of incidents/contamination, types of materials delivered, containers, off-loading operations, etc.

Thanks, Hank

Subject: Sampling/testing of sediments at Point Thomson in the proposed screeding/dredging area

Dear Hank,

I'd like to follow up on our discussion at the March 29, 2011 project update meeting regarding the need for sampling/testing of sediments at Point Thomson in the area proposed for dredging and screeding activities.
To confirm, your direction is that such sampling/testing is not currently required, although it may be recommended to establish baseline conditions.
Note that sediment samples were collected and tested in connection with the 2002/2003 Point Thomson project proposal in the general area and that data is available. The data indicated no contaminants of concern.

Because the 404 (b) (1) Guidelines can be interpreted to require such sampling/testing, please confirm if my interpretation above is correct.
However, if sampling/testing is needed, please advise when it would need to be done.

Regards,
Steve Calder

Information Needed:	Provide updated or revised design plans for the water supply pipeline infrastructure planned between the Central pad and the C-1 water source.
Level of Detail:	Include specific details regarding location of the pipeline relative to the airstrip access road, the height of the support timbers, diameter of the pipeline, and any design measures included to minimize impacts to caribou. Please provide a figure of the water pipeline design in section as well as updated GIS data.

Comments and Rationale:

Understanding the details of the updated water supply pipeline design between the Central Pad and the C-1 freshwater supply site is necessary for the analysis of potential impacts to caribou resulting from this component. Evaluation of the pros and cons of the updated design is also needed for the development of reasonable alternatives for Alternatives C, D, and E.

Response to Request for Information

RFI 111 – Updated Air Quality Data

Date Received: 4/27/2011

Date of Response: 5/13/11

To: Tim Gallagher, HDR Project Manager, Michael Allwright, HDR Associate Vice President

From: Vitaly Aizenbergy, ExxonMobil E&R

Note: Response to this RFI is based on application for Prevention of Significant Deterioration (PSD) Air Quality Permit that is currently being prepared by the Applicant. Although the Applicant is transmitting this RFI response in the interest of time, the Applicant has not yet completed the comprehensive review of the contents of the PSD Application. The information provided in this RFI response is from the relevant sections of the draft PSD permit application which has not been submitted to the Alaska Department of Environmental Conservation (ADEC). All emission unit inventories or their specifications are subject to change as detailed design work proceeds. Results of emission model and related calculations are also subject to change as the Applicant progresses preparation of the PSD Application. If material changes to numerical results contained in the transmitted documents occur, the Applicant will endeavor to notify HDR as soon as practicable.

Request No. 1

Emission calculation spreadsheets for both modeled and non-modeled pollutants. Please include:

- an updated emissions spreadsheet for criteria pollutants from construction and operation sources (including stationary equipment, mobile equipment, and transportation equipment). Existing spreadsheet is RFI 57 Rev 2. Add HAP emissions calculations to each equipment type.
- an updated emissions spreadsheet for GHGs from construction and operation sources (including stationary equipment, mobile equipment, and transportation equipment). Existing spreadsheet is RFI 30 Rev 2.
- an updated emissions spreadsheet for fugitive emissions, if changes occurred. Existing spreadsheet is RFI 100.

Response to Request No. 1

The response to Request No. 1 is separated into four sections below:

- Potential Total Emissions (PTE);
- Hazardous Air Pollutants (HAP);
- Greenhouse Gases (GHG); and
- Fugitive Emissions.

No changes have been made to mobile equipment or transportation units. Emission calculations for mobile equipment and transportation units received as responses to RFIs 30, 57, and 100 should be considered current.

Potential Total Emissions

Point Thomson Project air pollutant emissions are emitted by stationary emission units and non-road engines. Summaries of the potential total emissions from the Point Thomson during operations of the

production facility with drilling activities, construction of the production facility with drilling activities, and construction of the production facility including the overlap of starting up the production facility as construction comes to an end are provided below.

Total Potential Emissions from Point Thomson – Operations with Drilling

Description	Potential Emissions (tpy)					
	NO_X	CO	$PM_{2.5}$	PM_{10}	VOC	SO_2
Total Potential Emissions	219.2	442.6	15.6	17.1	48.2	24.9
Total Potential Emissions (excluding Non-road Engines)	162.1	118.8	13.1	14.5	30.8	24.3

[1]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway.

Total Potential Emissions from Point Thomson – Construction with Drilling

Description	Potential Emissions (tpy)					
	NO_X	CO	$PM_{2.5}$	PM_{10}	VOC	SO_2
Total Potential Emissions	203.3	1,148.0	21.4	23.2	115.3	21.8
Total Potential Emissions (excluding Non-road Engines)	145.6	818.2	18.8	20.6	97.6	21.1

[1]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway.

Total Potential Emissions from Point Thomson – Construction Overlap with Operations

Description	Potential Emissions (tpy)					
	NO_X	CO	$PM_{2.5}$	PM_{10}	VOC	SO_2
Total Potential Emissions	242.9	592.8	17.5	17.8	56.6	24.3
Total Potential Emissions (excluding Non-road Engines)	242.9	592.8	17.5	17.8	56.6	24.3

[1]Non-road engines are portable and transportable engines that remain at any single location for 12 months or less and otherwise meet the non-road engine criteria in 40 CFR 89.2. An engine used to propel a motor vehicle is a motor vehicle engine, not a non-road engine. A motor vehicle is a self-propelled vehicle designed for transporting persons or property on a street or highway.

The actual emissions for the combined construction and drilling activities will likely be much less than the potential emissions. The lower actual emissions are likely because any period of simultaneous construction and drilling will be less than one year. The actual emissions for the combined construction and production activities are likely to be much less than the potential emissions. The lower actual emissions are likely because the potential emissions are based on annual operation, while the transition period and the end of construction and the start of production is schedule to be much shorter.

The total potential emissions for were calculated using vendor data, U.S. Environmental Protection Agency (EPA) AP-42 emission factors, mass balances, and New Source Performance Standards

(NSPS) for reciprocating internal combustion engines. The total potential emissions were calculated assuming that each emission unit operates continuously (8,760 hours per year) at maximum load except for those emissions units that will be subject to owner requested operating restrictions. The potential emissions for restricted emission units were calculated assuming those emission units were operated at the maximum permitted load for the maximum allowed hours per year.

The detailed total potential emission calculations for Point Thomson are provided in the attached document, *Point Thomson Project RFI 111 PTE*.

Hazardous Air Pollutants

A summary of the total hazardous air pollutants during operations of the Point Thomson production facility with drilling activities are listed below.

Total Hazardous Air Pollutants from Point Thomson – Operations with Drilling[1]
Stationary Emission Units

Hazardous Air Pollutant	Total HAP Emissions (tpy)
Acetaldehyde	9.64E-02
Acrolein	1.42E-02
Benzene	6.98E-02
1,3 Butadiene	3.67E-03
Ethylbenzene	8.88E-02
Formaldehyde	1.29E+00
HCl	7.01E+00
n-Hexane	7.98E-04
Naphthalene	7.02E-03
Polycyclic Organic Matter	2.14E-02
Propylene Oxide	4.44E-02
Toluene	2.32E-01
1,1,1-Trichloroethane	4.70E-04
Xylenes	1.12E-01
Arsenic Compounds	6.78E-03
Beryllium Compounds	8.44E-04
Cadmium Compounds	1.32E-02
Chromium Compounds	1.15E-02
Lead Compounds	2.37E-01
Manganese Compounds	6.68E-02
Mercury Compounds	7.05E-03
Nickel Compounds	9.79E-03
Selenium Compounds	6.16E-03
Total	**9.35**

Total Hazardous Air Pollutants from Point Thomson – Operations with drilling[1]
Non-Road Engines

Hazardous Air Pollutant	Total HAP Emissions (tpy)
Benzene	3.14E-01
1,3 Butadiene	2.73E-03
Formaldehyde	1.08E-01
Polycylic Organic Matter	7.98E-02
Toluene	1.19E-01
Xylenes	8.19E-02
Total	**0.78**

The HAP emissions for were calculated using EPA AP-42 emission factors. The HAP emissions were calculated assuming that each emission unit operates continuously (8,760 hours per year) at maximum load except for those emissions units that will be subject to owner requested operating restrictions. The HAP emissions for restricted emission units were calculated assuming those emission units were operated at the maximum permitted load for the maximum allowed hours per year.

The detailed total potential emission calculations for Point Thomson are provided in the attached document, *Point Thomson Project RFI 111 HAP*.

Greenhouse Gases

Point Thomson Project GHG emissions of carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) result from combustion of fuel gas, diesel, and municipal solid waste. Methane emissions from natural gas extraction and natural gas liquids processing are negligible because the process occurs in a closed system. A summary of the estimated GHG emissions from the Point Thomson Project are below:

Greenhouse Gas Emissions from Point Thomson – Operations with Drilling

Description	Potential Emissions (tpy)			
	CO_2	CH_4	N_2O	CO_2e
Total Potential Emissions	301,829	8.662	1.398	302,444
Total Potential Emissions (excluding Non-road Engines)	237,662	6.059	0.878	238,061

*CO_2 Equivalent (CO_2e) is the total global warming impact and includes CO_2 emissions and the equivalent CO_2 global warming potential impact from CH_4 and N_2O. Per the 40 CFR 98 calculation requirements, CH_4 has a global warming impact 21 times greater than CO_2. Per the 40 CFR 98 calculation requirements, N_2O has a global warming potential of 310 times greater than CO_2.

Greenhouse Gas Emissions from Point Thomson – Construction with Drilling

Description	Potential Emissions (tpy)			
	CO_2	CH_4	N_2O	CO_2e
Total Potential Emissions	298,837	11.442	2.158	299,747
Total Potential Emissions (excluding Non-road Engines)	233,515	8.792	1.629	234,204

*CO_2 Equivalent (CO_2e) is the total global warming impact and includes CO_2 emissions and the equivalent CO_2 global warming potential impact from CH_4 and N_2O. Per the 40 CFR 98 calculation requirements, CH_4 has a global warming impact 21 times greater than CO_2. Per the 40 CFR 98 calculation requirements, N_2O has a global warming potential of 310 times greater than CO_2.

Greenhouse Gas Emissions from Point Thomson – Construction Overlap with Operations

Description	Potential Emissions (tpy)			
	CO_2	CH_4	N_2O	CO_2e
Total Potential Emissions	302,771	8.791	1.413	303,394
Total Potential Emissions (excluding Non-road Engines)	302,771	8.791	1.413	303,394

*CO_2 Equivalent (CO_2e) is the total global warming impact and includes CO_2 emissions and the equivalent CO_2 global warming potential impact from CH_4 and N_2O. Per the 40 CFR 98 calculation requirements, CH_4 has a global warming impact 21 times greater than CO_2. Per the 40 CFR 98 calculation requirements, N_2O has a global warming potential of 310 times greater than CO_2.

The methods for estimating GHG emissions for fuel combustion sources are applied in accordance with the guidance provided in Subpart C of the Mandatory Reporting of Greenhouse Gases Rule (40 Code of Federal Regulations Part 98) for Tier 1 units. The CO_2, CH_4, and N_2O emission estimates are calculated for all stationary emission units on an individual basis using Equation C-1 from 40 CFR 98 and then converted to tons per year from tones per year.

$$CO_2, CH_4, N_2O = 1 \times 10^{-3} * Fuel * HHV * EF \text{ (Equation C-1)}$$

Where:
CO_2, CH_4, N_2O = mass of GHG, tonnes per year
Fuel = Volume of fuel combusted per year
HHV = Default high heat value of the fuel from Table C-1, 40 CFR 98
EF = Fuel-specific default emission factors from Table C-1, 40 CFR 98

The per-equipment volume of fuel combusted is determined by assuming continuous operation at the equipment's maximum capacity, or according to any federally enforceable restrictions limiting the unit's annual operation.

The default factors From Table C-1 of 40 CFR 98 used to estimate GHG emissions from the Point Thomson project are:

Default Factors Used to Estimate GHG Emissions

Fuel Type	High Heat Value	CO_2 Emission Factor	CH_4 Emission Factor	N_2O Emission Factor
Distillate Fuel Oil No. 2	0.138 MMBtu/gallon	73.96 kg CO_2/MMBtu	3.0×10^{-3} kg CH_4/MMBtu	6.0×10^{-4} kg N_2O/MMBtu
Pipeline Natural Gas	1.028×10^{-3} MMBtu/scf	53.02 kg CO_2/MMBtu	1.0×10^{-3} kg CH_4/MMBtu	1.0×10^{-4} kg N_2O/MMBtu
Municipal Solid Waste	9.95 MMBtu/short ton	90.7 kg CO_2/MMBtu	3.2×10^{-2} kg CH_4/MMBtu	4.2×10^{-3} kg N_2O/MMBtu

The detailed total potential emission calculations for Point Thomson are provided in the attached document, *Point Thomson Project RFI 111 GHG*.

Fugitive Emissions
Fugitive VOC emissions from equipment leaks were estimated using current facility design data and the standard procedures prescribed in EPA's *Protocol for Equipment Leak Emission Estimates*. The fugitive VOC emissions were estimated at 50.5 tpy. Detailed calculations are provided in the attached document, *Point Thomson Project RFI 111 Fugitive VOC emissions*.

Requests No. 2, 4, 5, and 6

- No. 2 – Listing of emission sources/names/description corresponding to model input IDs as reflected in the AERMOD dispersion model input files.
- No. 4 – Contour plots with modeled design concentrations (e.g., 98th percentile 1-hour NO_2) overlain on aerials showing geographic location and facility layout with property boundaries.
- No. 5 – Tabular summaries of modeled output concentrations with comparison to applicable significant impact levels (SILs), PSD increments and AAAQS/NAAQS (the background concentrations should be shown in the AAQS tables).
- No. 6 – Dispersion model protocol or methodology.

Response to Requests No. 2, 4, 5, and 6
The responses to Requests No. 2, 4, 5, and 6 are attached. Please see the following attachment:

- *Point Thomson Project RFI 111 Air Quality Modeling and Impact Assessment*

Request No. 3
AERMOD model input and output files for each pollutant modeled, and meteorological input files.

Response to Request No. 3
The AERMOD model input and output files for each modeled pollutant along with the meteorological files are provided electronically under separate cover

Request No. 7
Provide an explanation of the PSD permitting plan for the construction/operations phases and the transition from the minor permit.

Response to Request No. 7
A PSD applicability analysis demonstrates that the Point Thomson Project triggers PSD requirements for nitrogen oxide (NO_X), carbon monoxide (CO), and fine respirable particulate matter ($PM_{2.5}$), and GHG. No current plans exist for the transition from the minor permit because ExxonMobil has asked

that Minor Permit, No. AQ1201MSS01, Revision 1, be rescinded effective May 25, 2011. Please refer to the Tables below for more details.

Point Thomson - Production Facility Minor Permit Applicability Analysis

Pollutant	Total Potential Emissions	Minor Applicability Threshold	Minor Applicable[1]
NO_X	162.1 tpy	40 tpy	Yes
CO	118.8 tpy	N/A	No
PM_{10}	14.5 tpy	15 tpy	No
$PM_{2.5}$	13.1 tpy	N/A	No
VOC	31.0 tpy	N/A	No
SO_2	24.3 tpy	40 tpy	No

Point Thomson - Production Facility PSD Permit Applicability Analysis

Pollutant	Total Potential Emissions	PSD Applicability Threshold	PSD Applicable
NO_X	162.1 tpy	250 tpy	No
CO	118.8 tpy	250 tpy	No
PM	14.5 tpy	N/A	No
PM_{10}	14.5 tpy	250 tpy	No
$PM_{2.5}$	13.1 tpy	250 tpy	No
VOC	31.0 tpy	250 tpy	No
SO_2	24.3 tpy	250 tpy	No
GHG[3]	237,669 tpy	250 tpy	Yes
CO_2e[4]	238,061 tpy	100,000 tpy	

Point Thomson - Production Facility PSD Permit Applicability Analysis if PSD Applicability Triggered for One Pollutant

Pollutant	Total Potential Emissions	PSD Applicability Threshold	PSD Applicable
NO_X	162.1 tpy	40 tpy	Yes
CO	118.8 tpy	100 tpy	Yes
PM	14.5 tpy	25 tpy	No
PM_{10}	14.5 tpy	15 tpy	No
$PM_{2.5}$	13.1 tpy	10 tpy	Yes
VOC	31.0 tpy	40 tpy	No
SO_2	24.3 tpy	40 tpy	No
CO_2e	238,061 tpy	75,000 tpy	Yes

Notes:
1. The permit applicability analyses are based on total potential emissions during operation.
2. A minor permit is not required because a PSD permit is required for this pollutant.

3. GHG is the sum of the GHG emissions on a mass basis (no global warming potentials applied).

4. CO_2e is the CO_2 equivalent emissions applying the global warming potential for each GHG from Table A-1, 40 CFR 98.

Subject: Fugitive Emissions

Dear François:

Fugitive volatile organic compound (VOC) emissions from equipment leaks were estimated using current facility design data and the standard procedures prescribed in the U. S. EPA's "Protocol for Equipment Leak Emission Estimates" (EPA-453/R-95-017, November 1995) (Protocol).

Pending the establishment of an Inspection and Maintenance Program to perform leak detection monitoring, the "Average Emission Factor Method" is used to estimate fugitive VOC emissions from equipment components such as valves, flanges, connectors, etc., at an Oil and Gas Production facility.

For each component in the current design, data were collected on the type of service (gas, light oil, etc.) and specific fluid in the component, based on the facility design. In accordance with the prescribed procedure, it is necessary to first estimate total organic compound (TOC) emissions. VOC emissions are then derived based on the ratio of the weight percentages of VOC to TOC, as explained in detail below.

The TOC emission factor from Table 2-4 "Oil and Gas Production Operations Average Emission Factors (kg/hr/source)" was obtained from the Protocol for each component, as a function of the planned service and anticipated fluid-type.

The table presents the TOC emission factors used for those components and types of service at the proposed facility. (Data are not presented for heavy oil service, as there will be no heavy oil in any of the lines. Similarly, data for connectors are not presented because all fittings will be welded. There will be no open-ended lines and data are not presented for this type either.). Data for the "other" equipment type is applied for equipment types other than connectors, flanges, open-ended lines, pumps, or valves. The "other" emission factor set was derived from compressors, diaphrams, drains, dump arms, hatches, instruments, meters, pressure relief valves, polished rods, relief valves, and vents.

Equipment Type	Service	TOC Emission Factor (F_A) (kg/hr)
Valves	Gas	4.5E-03
	Light Oil	2.5E-03
	Water/Oil	9.8E-05
Pump seals	Gas	2.4E-03
	Light Oil	1.3E-02

	Water/Oil	2.4E-05
Others	Gas	8.8E-03
	Light Oil	7.5E-03
	Water/Oil	1.4E-02
Flanges	Gas	3.9E-04
	Light Oil	1.1E-04
	Water/Oil	2.9E-06

Based on the current design, there are projected to be 3,962 components in service. These are comprised of 1,202 valves, 27 pump seals, 650 "others", and 2,083 flanges; mostly in gas and light oil service, as presented in the table:

Equipment Type	**Number In Gas Service**	**Number In Light Oil and Water/Oil service**	**Total Count**
Valves	480	722	**1,202**
Pump seals	0	27	**27**
Others	383	267	**650**
Flanges	917	1,166	**2,083**
Total	1,780	2,182	**3,962**

Based on the anticipated fluid-type, the weight-percentage of TOC and VOC was determined for each component. Hourly emission rates for TOC and VOC were calculated using the formulas:

$E_{TOC} = F_A \times WF_{TOC} \times N$

Where:

E_{TOC} = Emission rate of TOC from all equipment in the stream of a given equipment type (kg/hr)
F_A = Applicable average emission factor for the equipment type
WF_{TOC} = Average weight fraction of TOC in the stream
N = Number of pieces of equipment of the applicable equipment type in the stream

The weight fraction of TOC was calculated considering the expected contents of inorganics and water in the stream, in accordance with the Protocol.

And;

$E_{VOC} = E_{TOC} \times (WP_{VOC}/WP_{TOC})$

Where:

E_{VOC} = VOC mass emissions from the equipment (kg/hr);
E_{TOC} = TOC mass emissions from the equipment (kg/hr) calculated from the average emission factor,
WP_{VOC} = VOC Concentration in the equipment in weight percent;
WP_{TOC} = TOC concentration in the equipment in weight percent.

The resulting VOC hourly emission rates were then summed and the total converted to an annual rate, in pounds, and tons per year (tpy) assuming 24/7/52 service, for a total of **101,000 lb/year, or 50.5 tpy**. Detailed calculations are presented in the accompanying Excel spreadsheet.

The technical information included in this memo was provided by Joel Reisman in our Sacramento office. Please contact me if you have any questions and I can direct these to Mr. Reisman as well.

Kindest regards,

Marie Cardona
Interface Manager, Point Thomson Project

Notes:

1. Although the average emission factors are in units of kilogram per hour per individual source, it is important to note that these factors are most valid for estimating emissions from a population of equipment. The average factors are not intended to be used for estimating emissions from an individual piece of equipment over a short time period (i.e. 1 hr).
2. The "other" equipment type was derived from compressors, diaphrams, drains, dump arms, hatches, instruments, meters, pressure relief valves, polished rods, relief valves, and vents. This "other" equipment type should be applied for any equipment type other than connectors, flanges, open-ended lines, pumps, or
3. Connectors are threaded fittings like pipe couplers, reducers, unions, wye connectors, tees, crosses, etc.
4. Control valves will be catgetorized as Valves.
5. Blinds will be considered as Flanges.
6. Assumed every pump has a pump seal. Pump counts are based on equipment list. Spare pumps are counted and makes up 30% of the total pump count..
7. Valves, blinds, and flange counts are from MTO of 3D model by system provided by piping group.
8. Instrument, meter and pressure relief valve counts are from instrument count by system provided by I&C group.
9. Compressor counts are based on equipment list.

* Wet fraction based on wet basis

Notes:

1.Water/Oil emission factors apply to water streams in oil service with a water content greater than 50%, from the point of origin to the point where the water content reaches 99%. For water streams with a water content greater than 99%, the emission rate is considered negligible.

2.These factors are for total organic compound emission rates (including non-VOC's such as methane and ethane) and apply to light crude, heavy crude, gas plant, gas production, and off shore facilities. "NA" indicates that not enough data were available to develop the indicated emission factor.

3.The "other" equipment type was derived from compressors, diaphrams, drains, dump arms, hatches, instruments, meters, pressure relief valves, polished rods, relief valves, and vents. This "other" equipment type should be applied for any equipment type other than connectors, flanges, open-ended lines, pumps, or valves.

4. Control valves will be catgetorized as Valves.

5. Blinds will be considered as Flanges.
6. Connectors are threaded fittings like pipe couplers, reducers, unions, wye connectors, tees, crosses, etc.

Although the average emission factors are in units of kilogram per hour per individual source, it is important to note that these factors are most valid for estimating emissions from a population of equipment. The average factors are not intended to be used for estimating emissions from an individual piece of equipment over a short time period (i.e. 1 hr).

AIR QUALITY MODELING AND IMPACT ASSESSMENT

1 Dispersion Modeling Overview

ExxonMobil is required to submit an ambient air quality (dispersion modeling) analysis of the Point Thomson Project to demonstrate compliance with all applicable National and Alaska Ambient Air Quality Standards (AAQS) and PSD Class II increment limits. This assessment of ambient air quality impacts must be based on current EPA-approved models and methodologies.

As of July 1, 2011, the Point Thomson Project is subject to PSD applicability requirements for greenhouse gas (GHG) emissions. The Point Thomson Project GHG potential to emit (PTE) will exceed the PSD permit applicability thresholds of 250 tpy and 100,000 tpy for GHG (by mass) and GHG (by CO_2 equivalent (CO_2e)), respectively, triggering the requirement that an air quality analysis be conducted for each regulated New Source Review (NSR) pollutant emitted in a significant amount (40 CFR 52.21(m)(a)). Because potential NO_X, CO, and $PM_{2.5}$ emissions exceed the 40 tpy, 100 tpy, and 10 tpy PSD applicability thresholds, respectively, these emissions are subject to PSD review under 18 AAC 50.306. Ozone (O_3) impacts were not included in the air quality analysis because the increase in potential VOC emissions is less than the 40 tpy PSD applicability threshold and less than the 100 tpy modeling applicability threshold. SO_2 impacts were not included in the air quality analysis because potential SO_2 emissions do not exceed the PSD applicability threshold, of 40 tpy nor the minor air quality permitting requirement threshold of 18 AAC 50.502.

Permitting under the PSD regulations requires a demonstration that emissions will not interfere with the attainment or maintenance of the AAQS. In the case of a PSD assessment, the demonstration must also include an assessment of increment consumption.

Because this demonstration is required, ExxonMobil has compiled a dispersion modeling analysis following the procedures described in subsequent sections. The results of the analyses demonstrate that ambient impacts due to emissions from the Point Thomson Project will not interfere with the maintenance of National and Alaska AAQS or adversely affect PSD increment compliance.

2 Meteorological Data

Following EPA guidance (40 CFR Part 51, Appendix W), a single year (September 1, 2009 through August 31, 2010) of site specific meteorological data collected at Point Thomson were used with AERMOD to estimate pollutant impacts. AERMET requires a minimum of hourly surface observations of wind speed, wind direction, temperature, and cloud cover and corresponding twice-daily upper air meteorological soundings. ADEC reviewed the Point Thomson meteorological data set and determined the data to be PSD-quality on April 21, 2011.

DRAFT

Hourly site-specific surface meteorological data collected at the Point Thomson Project location were used with corresponding upper air meteorological data collected at Barrow, Alaska. Coincident hourly surface meteorological data collected at the National Weather Service (NWS) Automated Surface Observation System (ASOS) station at the Deadhorse, Alaska Airport were used to substitute any missing hourly wind, temperature, and cloud cover data in the site-specific meteorological data set. Table 6-1 provides the hourly site-specific meteorological data capture statistics for the monitoring year used for the dispersion modeling demonstration.

Figure 6-1 depicts a wind rose of the site-specific wind data collected during the monitoring year and shows the predominant winds are from the west-southwest, east-northeast, and east. This wind pattern facilitates the transport of emissions to the northeast and southwest edges of the proposed Central Pad and Ice Pad, respectively.

AERMET (version 11059) uses the upper air and surface meteorological data with site-specific geophysical inputs to calculate the atmospheric boundary layer parameters supplied to AERMOD for use in the air dispersion model algorithms. The geophysical input parameters are albedo, Bowen ratio, and surface roughness length. The procedures used to determine these input parameters are outlined in the EPA *AERMOD Implementation Guide* (Revised March 2009) and the ADEC *AERMET Geometric Means, How to Calculate the Geometric Mean Bowen Ratio and the Inverse-Distance Weighted Geometric Mean Surface Roughness Length in Alaska*, (Revised June 2009). The recommendations for determining the geophysical input parameters summarized below.

Albedo is based on a simple unweighted arithmetic mean for a representative domain defined by a 10 kilometer (km) by 10 km grid with a resolution of 1 square kilometer (km^2) and centered on the surface measurement site.

Bowen Ratio is based on simple unweighted geometric mean for the same representative domain as used to define the site-specific albedo.

Surface Roughness Length is based on an inverse-distance weighted geometric mean for a default upwind distance of one km relative to the surface meteorological measurement site. Surface roughness length may be varied by sector to account for variations in land cover near the measurement site. However, the sector widths should be no smaller than 30 degrees.
In addition to dependency on land-use classifications, the AERMET geophysical parameters are also seasonally dependent. AERMET uses a definition of monthly composition of seasons that is much different than that experienced on Alaska's North Slope. Therefore, the AERMET geophysical parameters were supplied to AERMET on a monthly basis to reflect more representative seasonal patterns for Point Thomson. The following monthly definitions of the seasons are based on climate records for Deadhorse, Alaska and have been approved by the Alaska Department of Environmental Conservation (ADEC) for prior air permit activities:

- Summer (June through September): vegetation is emerging or partially green, the period when the mean daily high temperatures rise above 32 °F.

- Winter (October through May): mean daily high temperatures rarely exceed 32 °F and the surface is covered with snow and ice.

Table 6-2 provides geophysical parameters segregated by season for meteorological stations located on the North Slope Coastal Plain and the Beaufort Sea.

Figure 6-2 depicts the one hundred km^2 grid superimposed over an aerial photograph and centered over the Point Thomson meteorological monitoring station location. Figure 6-2 shows the land use classifications for the on km^2 sections within the one hundred km^2 domain.

Figure 6-3 depicts the 3.14 km^2 circular area superimposed over an aerial photograph and centered over the Point Thomson meteorological monitoring station location. Figure 6-3 also provides assigned sector numbers used to determine the surface roughness length input parameters.

Table 6-3 provides the AERMET geophysical parameters used in AERMET for processing the Point Thomson Project site-specific meteorological data. The latest version of AERMET includes the requirement to specify a secondary set of surface characteristics used when NWS winds are substituted for missing site-specific hourly wind data. This is done to ensure that appropriate geophysical surface parameters will be used with the referenced wind data. Table 6-4 provides the AERMET secondary geophysical parameters used in AERMET for processing the Deadhorse NWS ASOS wind data.

3 Emission Unit Descriptions and Locations

The Point Thomson Project emission unit inventory consists of emission units for the operation of the production facility, emission units associated with drilling, workover and miscellaneous support, and emission units associated with the construction of the production facility.

The emission units for the operation of the production facility consist of two fuel gas-fired turbines, two dual fuel-fired turbines, two waste incinerator, four reciprocating engines driving standby generators, two reciprocating engines driving fine water mist pump engines, and two flares. Three scenarios were modeled:

- Operations with drilling, which represents the permanent stationary source;
- Construction with drilling: and
- The transition from construction to operations, during which some of the construction and operations emission units will be running simultaneous.

All stacks will be vertical and uncapped, so information regarding stack orientation is not included in those tables.

Other emission unit inventory information involving the dispersion modeling is provided below. Specifically, the dispersion modeling:

- Does not include the Emission Units 209, 210, 221, and 222, which will be located on the C-1 pad during construction because these small emission units are located approximately 3.2 km (2 miles) from the Central Pad;
- Does not include Emission Units 107 through 111 because these emission units are emergency engines that do not operate more than 100 hour per year, each;
- Does not include Emission Units 25 through 27 and 30 through 35 because these small portable heaters are intermittently used oil field service equipment; and
- Includes well test equipment at annualized emission rates in accordance with EPA guidance regarding intermittently used equipment.

4 GEP and Downwash

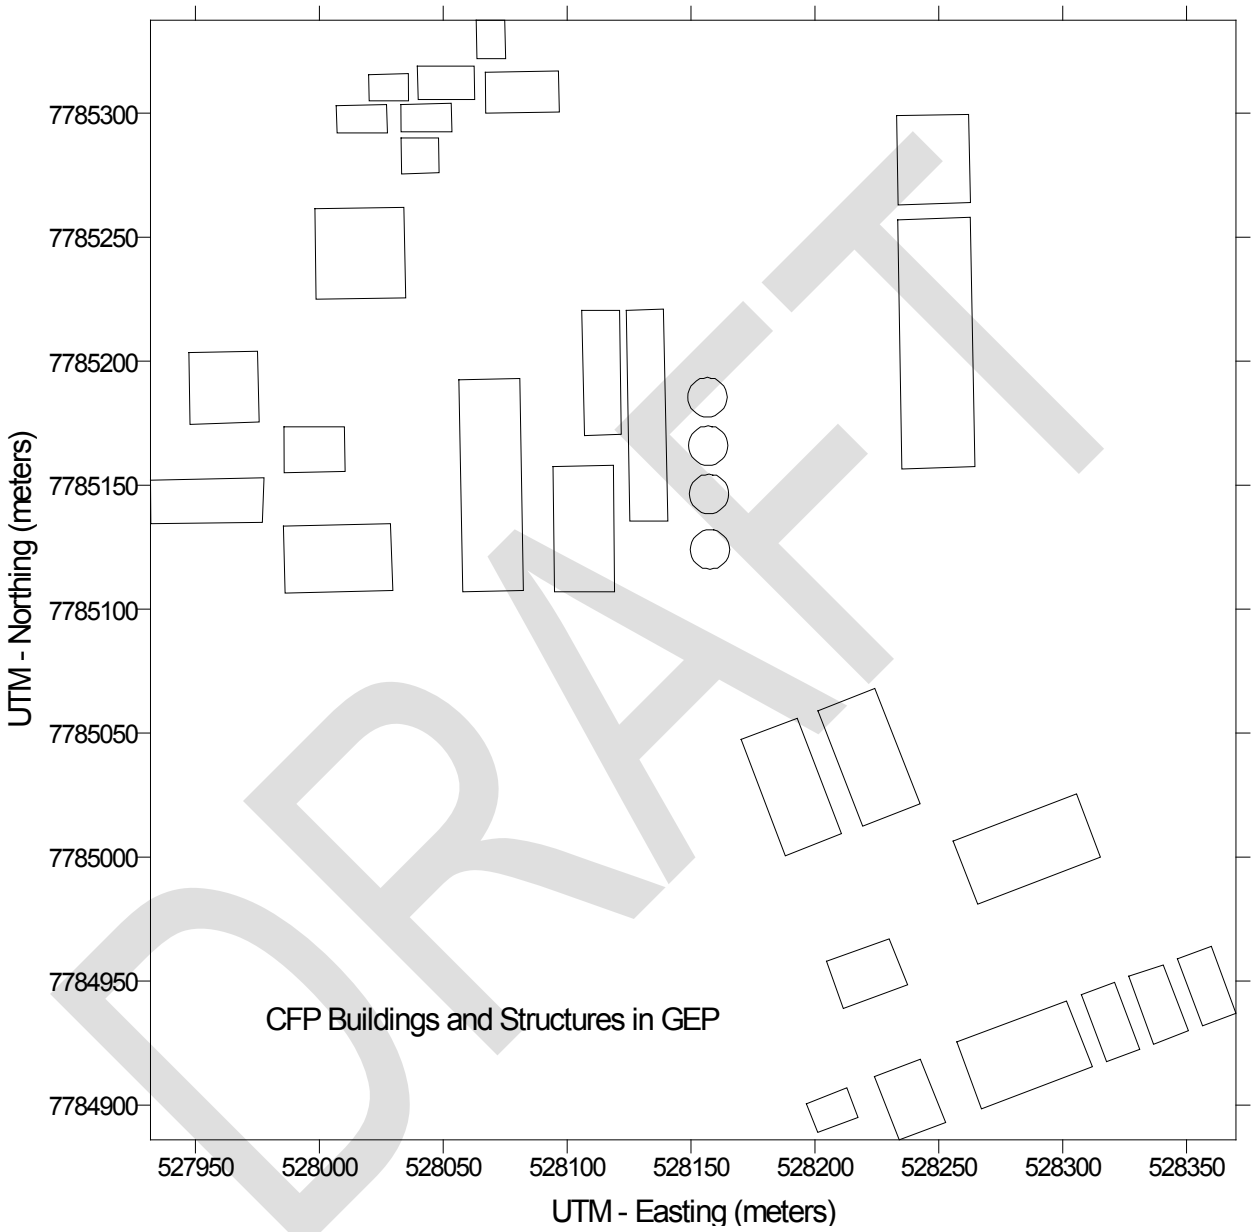
A good engineering practice (GEP) stack height evaluation following the procedures consistent the EPA *Guideline for Determination of Good Engineering Practice Stack Height* (EPA-450/4-80-023R, June 1985) was conducted to determine the potential for building wake effects.

GEP stack height (H_{GEP}) as defined in 40 CFR Part 51 is expressed as:

$$H_{GEP} = H_b + 1.5L$$

where:

H_b = the building height



L = the lesser of the building height or maximum projected width (where maximum projected width may be regarded as the greatest horizontal distance covered by the building when viewed from any angle).

This formula defines the stack height at which building wake effects on the stack plume may be considered insignificant. If the actual stack height is less than GEP stack height (H_{GEP}), then the proximity of the stack to surrounding structures (horizontal location) is evaluated to determine if wake effects are applicable. A building or structure is considered sufficiently close to a stack to cause wake effects when the minimum distance between the stack and the building is less than or equal to five times the lesser of the height or projected width of the building (5L). This distance is commonly referred to as the building's region of influence.

Direction-specific building downwash dimensions were calculated using the Building Profile Input Program, PRIME version (BPIP PRIME), version 04274. Building coordinates and heights for each structure that could influence a modeled emission unit were entered into BPIP PRIME and the output dimensions were used to ensure that no stack exceeds good engineering practice (GEP) stack height and to provide direction-specific downwash dimensions to the AERMOD model. The buildings and structures used in the downwash analysis are denoted in Figures 6-6 and 6-7 along with the emission unit locations.

DRAFT

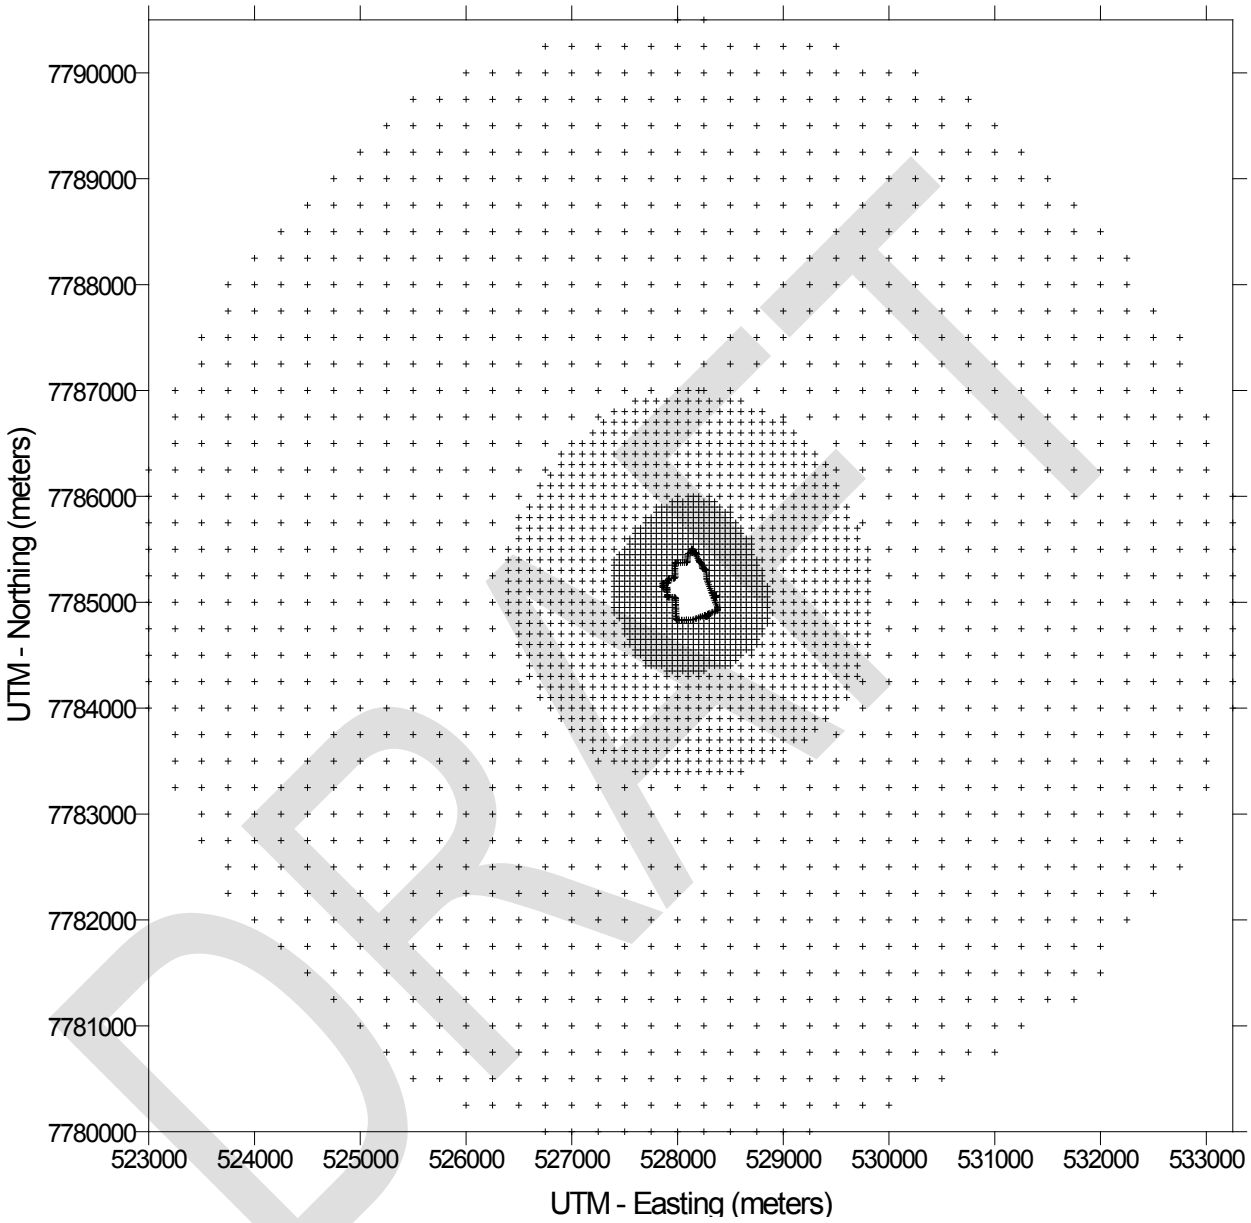
5 Model Receptors



The Point Thomson Project will be completed in a number of steps, including the complete removal of all facilities from the Central Pad to enlarge the Central Pad to accommodate the planned production facility. Figure 6-5 depicts the extent of Central Pad upon completion of construction of the Point Thomson Project production facility.

EPA defines ambient air as that portion of the atmosphere, external to buildings, to which the general public has access. For the purpose of modeling source emissions, the area to which ExxonMobil controls public access is not ambient air. Therefore, model receptors were placed only along and outside of the pad edges to represent the ambient air quality boundary. In addition, no receptors were placed over worker housing or camp areas since all workers are active and "on-call" at all times.

Figure 6-8, show receptor grids for the Central Pad. Near grid receptors were spaced at 20 m intervals along the pad edges and outward to a distance of 500 m at 50 m intervals. Beyond the near grid, receptors were placed outward to 1,500 m from pad edge at 100 m intervals to comprise a middle grid. Beyond the middle grid, a far grid was used comprised of receptors placed outward to 5,000 m from pad edge at 250 m intervals. The AERMOD terrain data processor, AERMAP, was not used to calculate discrete receptor elevations and hill height scales, because the area surrounding the proposed project is the Beaufort Sea and North Slope coastal plain and can be appropriately be modeled as flat terrain.

DRAFT

Figure 6-8. Point Thomson – Central Pad Receptor Grid

DRAFT

6 Selection of Rural Dispersion Coefficients

AERMOD includes an urban option to account for the dispersion of pollutants during night-time convective conditions that occur due to “urban heat island” effects. 40 CFR Part 51, Appendix W, Section 7.2.3 provides the basis for determining whether the source is classified as an urban or rural area. Specifically, a circular area (A_o), circumscribed by a 3 km radius circle about the source is used for the determination and either the land use or population density within A_o is used to determine the urban or rural classification. The area, A_O, circumscribing the Point Thomson Project almost entirely consists of open water and undeveloped land. Therefore, rural dispersion coefficients were used in the modeling demonstration.

7 Conversion of NO_X to NO_2

To demonstrate compliance with the ambient NO_2 standards, the Plume Volume Molar Ration Method (PVMRM) approach was used in accordance with EPA guidance. The March 1, 2011 EPA guidance memo regarding modeling of NO_X emissions to comply with the newly-promulgated NO_2 1-hour NAAQS outlines a three-tiered approach. Tier 1 assumes full conversion of NO to NO_2. Tier 2 multiplies the Tier 1 predicted concentration by empirically derived NO_2/NO_X ratio, with 0.75 as the national default ratio. The Tier 3 approach outlines detailed screening methods that may be considered on a case-by-case basis with the Ozone Limiting Method (OLM) identified as the screening technique for point sources. Another screening method that can also be used is PVMRM. According to the EPA guidance memo, both options account for ambient conversion of NO to NO_2 in the presence of ozone.

Unlike OLM, PVMRM allows for the oxides of nitrogen and ozone interactive chemistry within the downwind plume by computing the number of moles of available O_3 allowed to react with the number of moles of available NO and form the regulated pollutant NO_2. PVMRM has the capability to perform the calculation for multiple plumes accounting for aggregate conversion downwind from all modeled sources simultaneously.

Because of the robustness of the NO_X reactive chemistry algorithm, ExxonMobil applied PVMRM to the modeled NO_X emissions to calculate short- and long-term NO_2 concentrations for comparison to ambient air quality values. The PVMRM algorithm requires in-stack ratios of NO_2/NO_X emissions as well as background ozone concentrations.

Prior application of PVMRM at Point Thomson has invoked default and ADEC-approved values of 0.1 and 0.3 depending on the type of emission unit and fuel fired. While guidance suggests a higher default value to capture all possible emission unit types, in-stack ratio data from EPA Region 9 indicates that the emission unit types at Point Thomson should have ratios of less than 0.1. Based on this guidance, a PVMRM in-stack ratio value of 0.1 was applied for this analysis as had been done in prior analyses submitted to and reviewed by the ADEC. Further, the default value of 0.9 is used as the ambient NO_2/NO_X equilibrium ratio.

DRAFT

The ambient ozone concentrations needed to perform the PVMRM reactive chemistry calculations are provided to AERMOD in an attendant hourly background concentration file. This background ozone data was developed from the onsite monitoring data set. Missing periods from the hourly ozone data were interpolated or filled with monthly average values determined from valid periods in the ozone record. More specifically, periods of missing values were filled with average ozone concentration values occurring during that month at that time period.

The monitored ozone values were measured at Point Thomson and were influenced by pad operations, including drilling that was conducted at Point Thomson during the monitoring period (September 1, 2009 – August 31, 2010). The ozone monitoring record is fairly complete with only 1,099 hours of missing periods of data. These missing periods were filled by applying the monthly average ozone concentrations as shown in Table 6-8.

Table 6-8. Point Thomson – Hourly Ozone Data

Month	Average Hourly Ozone Value (ppb)
September 2009	26.7
October 2009	24.2
November 2009	30.2
December 2009	27.9

April 2010	19.8
May 2010	20.5
June 2010	28.0
July 2010	17.7
August 2010	15.9

DRAFT

8 Ambient Monitoring Data

To demonstrate compliance with the AAAQS, ambient background data is required to be added to form an aggregate impact. The ambient data obtained at Point Thomson is current and representative of the site and therefore appropriate to be used. The background concentrations are summarized in Table 6-9, with the exception of the 1-hour NO_2 data.

Because of relevancy and proximity, the background NO_2 data can be paired in time and space with the modeled concentrations to better examine combined impacts. This approach, which is allowed by EPA, was used to form aggregate NO_2 concentrations for that portion of the data that is overlapping. For the non-coincident portion, the monthly average values were used to demonstrate compliance.

This methodology required the comparison of same time modeled concentrations with same time monitored concentrations on a daily basis and the adding of the 8th highest daily impacts together with the background values. The values to derive the combined impacts were based on the most recent AERMOD output options utilizing the post processing capabilities in producing the highest-eighth highest values for use in the analysis.

The hourly monitored NO_2 data were previously submitted to ADEC and are again provided electronically with this application

9 Modeling Results

In addition to the existing annual NO_2 and 1- and 8-hour CO ambient air quality standards, EPA has recently promulgated new AAQS for NO_2 and $PM_{2.5}$. ADEC recently adopted the $PM_{2.5}$ ambient air quality standards, and so a demonstration of compliance with these new ambient standards is required. ADEC has not yet adopted the ambient 1-hour NO_2 standard. However, a demonstration of compliance with this ambient standard is provided because ADEC is expected to adopt the standard before issuing the Point Thomson final PSD permit. A summary of the various significant impact levels (SILs), AAQS, increments, and ambient significant monitoring levels is provided in Table 6-9.

The model results for ambient air quality are reported in Table 6-10. Isopleths showing the 1-hour average NO_2 impacts for operations with drilling are shown in Figure 6-9. Isopleths for the annual $PM_{2.5}$ and 24-hour $PM_{2.5}$ are provided in Figures 6-10 through 6-11.

The ambient air quality modeling results do not include impacts from other stationary sources because no other stationary sources exist or are planned for the Point Thomson vicinity. The nearest existing stationary source is the Badami Development Facility (Badami), located approximately 30 miles (48 km) west of the Point Thomson Central Pad. The nearest exploration block unit for the planned Shell Kulluk Drilling Unit (Kulluk) program in the Beaufort Sea is approximately 20 miles (32 km) north of the Point Thomson Central Pad. Both Badami

DRAFT

and Kulluk are located far outside the Point Thomson significant impact area.

The model results for increment are reported in Table 6-11. An increment has not yet been promulgated for 1-hour ambient NO_2. Increments have been established for annual and 24-hour $PM_{2.5}$, but ADEC has not yet developed the procedures for examining those increments. Lacking an approved mechanism, an examination of $PM_{2.5}$ increment has not been provided. Increment isopleths for the annual NO_2 are provided in Figure 6-12.

Table 6-9. Pollutant SIL, AAQS, PSD Class II Increments, and *De Minimis* Levels

Pollutant	Averaging Period	SIL ($\mu g/m^3$)	AAQS ($\mu g/m^3$)	PSD Class II Increment ($\mu g/m^3$)	Significant Monitoring Level ($\mu g/m^3$)
Nitrogen Dioxide, NO_2	Annual	1.0	100	25	14
	1-Hour[1]	NA[2]	188[3]	NA[4]	NA[4]
Carbon Monoxide, CO	8-Hour	500	10,000[5]	NA[6]	575
	1-Hour	2,000	40,000[5]	NA[6]	NA[6]
Particulate Matter, $PM_{2.5}$	Annual	0.3	15[7]	4	NA[8]
	24-Hour	1.2	35[9]	9	4

[1] EPA announced a new 1-hour NO_2 NAAQS on January 22, 2010. Alaska has three years after the effective date to submit a revised SIP that addresses the 1-hour NO_2 standard.
[2] No SIL for the 1-hour NO_2 standard has been promulgated. EPA has recommended the use of an "interim" one-hour NO_2 SIL of 7.6 $\mu g/m^3$, which is 4 percent of the one-hour NO_2 NAAQS.
[3] To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 100 ppb (188 $\mu g/m^3$).
[4] Not Applicable. No PSD Increment or monitoring *de minimis* levels have been promulgated for the one-hour NO_2 averaging period.
[5] Not to be exceeded more than once each year.
[6] Not Applicable. PSD increments have not been established for CO. No monitoring *de minimis* levels have been established for the 1-hour CO averaging period.
[7] To attain this standard, the 3-year average of the weighted annual mean $PM_{2.5}$ concentration must not exceed 15.0 $\mu g/m^3$.
[8] Not Applicable. A monitoring *de minimis* level has not been established for the annual $PM_{2.5}$ averaging period.
[9] To attain this standard, the 3-year average of the 98th percentile of 24-hour concentrations must not exceed 35.0 $\mu g/m^3$.

Note:

1. CO_2e is the CO_2 equivalent emissions applying the global warming potential for each GHG from Table A-1, 40 CFR 98. Global warming potentials are:
   Carbon Dioxide: 1
   Methane: 21
   Nitrous Oxide: 310
2. The PSD applicability threshold is in units of short tons per year (tpy) opposed to metric tons per year (tonnes/yr).
3. Potential CO_2e, CO_2, CH_4, and N_2O emissions from dual fired turbines in $SoLoNO_X$ mode and non-$SoLoNO_X$ mode are the same.

Table 2. Point Thomson Production Facility - Stationary Equipment Potential CO_2 Emissions

Emission Unit		CO_2 Emission Factor		Maximum	Maximum Operation			Potential CO_2 Emissions	Potential CO_2 Emissions	Potential CO_2 Emissions
No.	Identification	Reference		Heat/Fuel Consumption	Construction and Operations	Construction and Drilling	Operations and Drilling	Construction and Operations	Construction and Drilling	Operations and Drilling

				Total Potential CO_2 Emissions for All Emission Units				302,771.1 tpy	298,837.1 tpy	301,829.1 tpy

Notes:
1. Distillate No. 2 default high heat value: 0.138 MMBtu/gallon
2. Pipeline natural gas default high heat value: 1.028E-03 MMBtu/scf
3. Municipal solid waste default high heat value: 9.85 MMBtu/short ton
4. Potential CO_2 emissions from dual fired turbines in SoLoNO$_X$ mode and non-SoLoNO$_X$ mode are the same.

Table 3. Point Thomson Production Facility - Stationary Equipment Potential CH_4 Emissions

Emission Unit		CH_4 Emission Factor		Maximum	Maximum Operation			Potential CH_4 Emissions	Potential CH_4 Emissions	Potential CH_4 Emissions
No.	Identification	Reference		Fuel Consumption	Construction and Operations	Construction and Drilling	Operations and Drilling	Construction and Operations	Construction and Drilling	Operations and Drilling

					Total Potential CH_4 Emissions for All Emission Units			8.791 tpy	11.442 tpy	8.662 tpy

Notes:
1. Distillate No. 2 default high heat value: 0.138 MMBtu/gallon
2. Pipeline natural gas default high heat value: 1.03E-03 MMBtu/scf
3. Municipal solid waste default high heat value: 9.85 MMBtu/short ton
4. Potential CH_4 emissions from dual fired turbines in $SoLoNO_X$ mode and non-$SoLoNO_X$ mode are the same.

Table 4. Point Thomson Production Facility - Stationary Equipment Potential N_2O Emissions

Emission Unit		N_2O Emission Factor		Maximum	Maximum Operation			Potential N_2O Emissions	Potential N_2O Emissions	Potential N_2O Emissions
No.	Identification	Reference		Fuel Consumption	Construction and Operations	Construction and Drilling	Operations and Drilling	Construction and Operations	Construction and Drilling	Operations and Drilling

Notes:
1. Maximum capacity of the turbines is the nominal capacity at ISO conditions.
2. Dual fired turbines are restricted to 1,000 hr/yr while firing on ULSD, and unrestricted operation while firing on fuel gas.
3. ULSD = Ultra Low Sulfur Diesel
4. Solar 70 Taurus Turbine operation in non-SoLoNOx mode is limited to 500 hr/yr, total for all four turbines.

				Total Potential NO_X Emissions Excluding Non-road Engines				242.9 tpy	145.6 tpy	162.1 tpy
				Total Potential NO_X Emissions for All Emission Units				242.9 tpy	203.3 tpy	219.2 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. NSPS Subpart IIII emission standard for fire water pump engines.
3. NSPS Subpart IIII NO_X + NMOC emission standard for the fire water pump engines and Tier 3.
4. Drill rig heaters and boilers vendor data is for Low NOx Burners, with a guaranteed NOX emission concentration of 25 ppm or less when firing ULSD, equivalent to a NOX emission rate of 0.027 lb/MMBtu.
5. Inlet air heating on combustion turbines.
6. Higher potential NO_X emissions result from dual fired turbines firing 500 hr/yr on ULSD in $SoLoNO_X$ mode, than firing 500 hr/yr ULSD in non-$SoLoNO_X$ mode.

			Total Potential CO Emissions Excluding Non-road Engines					592.8 tpy	818.2 tpy	118.8 tpy
			Total Potential CO Emissions for All Emission Units					592.8 tpy	1,148.0 tpy	442.6 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. Inlet air heating on combustion turbines.
3. Each turbine has catalytic oxidation which controls 90 percent of CO emissions.
4. Highest potential CO emissions result from turbines firing 500 hr/yr on fuel gas in non-SoLoNO$_X$ mode.
5. Catalytic oxidation controls 85 percent of potential non-SoLoNOx mode emissions.

			Total Potential PM/PM_{10} Emissions Excluding Non-road Engines					17.8 tpy	20.6 tpy	14.5 tpy
			Total Potential PM/PM_{10} Emissions for All Emission Units					17.8 tpy	23.2 tpy	17.1 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. NSPS Subpart IIII emission standard for fire water pump engines.
3. Potential PM emissions from dual fired turbines in $SoLoNO_X$ mode and non-$SoLoNO_X$ mode are the same.
4. Fuel factor for waste is 9,570 dscf/MMBtu.

Table 5. Point Thomson Production Facility - Potential $PM_{2.5}$ Emissions

Emission Unit		$PM_{2.5}$ Emission Factor		Maximum	Maximum Operation			Potential $PM_{2.5}$ Emissions		
No.	Identification	Reference		Capacity	Construction and Operations	Construction and Drilling	Operations and Drilling	Construction and Operations	Construction and Drilling	Operations and Drilling

				Total Potential $PM_{2.5}$ Emissions Excluding Non-road Engines				17.5 tpy	18.8 tpy	13.1 tpy
				Total Potential $PM_{2.5}$ Emissions for All Emission Units				17.5 tpy	21.4 tpy	15.6 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. NSPS Subpart IIII emission standard for fire water pump engines.
3. Potential $PM_{2.5}$ emissions from dual fired turbines in $SoLoNO_X$ mode and non-$SoLoNO_X$ mode are the same.
4. $PM_{2.5}$ emission factors are used where available.

Table 6. Point Thomson Production Facility - Potential VOC Emissions

Emission Unit		VOC Emission Factor		Maximum	Maximum Operation			Potential VOC Emissions		
No.	Identification	Reference		Capacity	Construction and Operations	Construction and Drilling	Operations and Drilling	Construction and Operations	Construction and Drilling	Operations and Drilling

	Fugitive emissions from equipment leaks	EPA's Protocol for Equipment Leak Emission Estimates			N.A.	N.A.	N.A.	N.A.	N.A.	50.5 tpy
			Total Potential VOC Emissions Excluding Non-road Engines					56.6 tpy	97.6 tpy	31.0 tpy
			Total Potential VOC Emissions for All Emission Units					56.6 tpy	115.4 tpy	98.9 tpy

Notes:
1. Fuel gas has a heat content of 1,020 Btu/scf.
2. Inlet air heating on combustion turbines.
3. Higher potential VOC emissions result from dual fired turbines firing 8,760 hr/yr on fuel gas, than firing 1,000 hr/yr on ULSD and 7,760 hr/yr on fuel gas.
4. Each turbine has catalytic oxidation which controls 72 percent of VOC emissions.
5. Highest potential VOC emissions result from dual fired turbines firing 500 hr/yr on ULSD in non-SoLoNO$_X$ mode.
6. Catalytic oxidation controls 68 percent of potential non-SoLoNOx mode emissions.

Notes:
1. Diesel fuel is assumed to have a sulfur content of 15 ppmw (0.0015 wt. pct.) and a heat content of 137,000 Btu/gal.
2. Diesel engine heat rate assumed to be 7,000 Btu/hp-hr.
3. High pressure fuel gas has a heat content of 1,020 Btu/scf and H_2S of 100 ppmv.
4. Low pressure fuel gas has a heat content of 1,020 Btu/scf and H_2S of 300 ppmv.
5. The Solar Taurus 70 turbine has a heat rate of 10,318 Btu/kW-hr.
6. Higher potential SO_2 emissions result from dual fired turbines firing 8,760 hr/yr on fuel gas, than firing 1,000 hr/yr on ULSD and 7,760 hr/yr on fuel gas.
7. Higher potential SO_2 emissions result from dual fired turbines firing 500 hr/yr on ULSD in $SoLoNO_X$ mode, than firing 500 hr/yr ULSD in non-$SoLoNO_X$ mode.

Conceptual Scenarios for Alternatives 3a (C), 3b (D), and 4 (E)

Practicability of Point Thomson Draft EIS Alternatives
ExxonMobil Technical Brief #1 – Well Pad Locations

As described in the response to RFI 52, a key purpose of the Project is to provide the necessary footprint for Project operations that will accommodate currently envisioned future development options to accomplish full field development with the least overall environmental impact.

From a reservoir development perspective, the optimal sites for the well surface locations would be offshore because the Thomson Sand reservoir is predominately located offshore and drilling vertical wells into the reservoir is less complex. However, drilling from manmade or natural offshore islands was not pursued due to the impact such activities would have on the environment. The proposed onshore well pad locations, positioned near the coastline, allow wells to be drilled that will adequately develop the reservoir while reducing environmental impacts. This configuration, however, already involves several significant trade-offs for the Project and Point Thomson development:

- Full development of the field relies on being able to reach bottomhole targets located offshore from these well pad locations to effectively delineate and develop the Thomson Sand reservoir
- Drilling from onshore well pads makes it necessary to drill wells with longer horizontal departures from the surface location (throw) and greater measured depth, increasing the potential that wells may not be able to reach their targeted bottomhole locations and increasing the cost of and complexity of drilling the wells.
- The current pad locations will provide adequate access to necessary bottomhole locations to develop the Thomson Sand, given the 13,000 ft technical limit for drillwell throw.

Although there is good quality seismic data and numerous wells have been drilled (16 historical and 2 recent) that define the location and areal extent of the reservoir, there will always be some uncertainty in the interpretation and definition of the reservoir, in both structure and quality, and this requires retaining flexibility in placing well bottomhole targets.

- Preserving maximum lateral and offshore reach is necessary to allow for full investigation of the extent, nature and connectivity of the reservoir.
- The reservoir understanding should be expected to change as additional wells are drilled, more information gathered, and the reservoir interpretation refined as a result of new information. Potential changes in the reservoir understanding and subsequent changes to bottomhole targets can be managed by maintaining access to as much of the reservoir area located offshore as possible. Onshore and nearshore bottomhole targets alone would not accommodate potential changes in the reservoir understanding.
- Pad location further inland from the coast will increase the throw on all wells and potentially preclude the ability to reach portions of the reservoir necessary for full field development. This may lead to additional pads being needed in the future to reach bottomhole targets that cannot be reached from a pad that has been located further inland.

The East and West pad have been located to access bottomhole targets for current development of the Thomson Sand reservoir and potential future development plans (gas sales or expanded gas cycling).

- The East Pad has been moved west to the North Staines area compared to the earlier 2002 work plans which located the East Pad closer to ANWR. The current East Pad location incorporates an existing gravel pad into the Project plan to reduce new footprint and environmental impacts.
- The West Pad has been shifted east to provide as much coverage of the field as possible within the 13,000 ft throw technical drilling limit.
- These current pad locations allow access to the Thomson Sand reservoir for gas/condensate development, without requiring additional pads for Thomson Sand gas sales development.

Practicability of Point Thomson Draft EIS Alternatives
ExxonMobil Technical Brief #2 – Centrifugal Compressors (rev 1.)

August 20, 2014

Summary

There are two gas compression technologies that can be considered for the gas injection application required at Point Thomson, reciprocal and centrifugal. Both compression technologies were carefully evaluated to ensure that the equipment selected met the Project's technical and performance requirements. The reciprocating compressors were determined to be the sole choice that meets the Project's purpose and need; they are the only proven technology available meeting the Project's design flow rate, extremely high pressure requirements, and range of operating conditions this facility may be required to contend with due to uncertainties in reservoir performance and high pressure gas/liquid separation performance.

Centrifugal compressors are not considered practicable in this application and do not meet the Project's purpose and need because they are not available in industry at the size required for the Project. Additionally, centrifugal compressors do not satisfy the operating flexibility requirements driven by reservoir and high pressure separation performance uncertainty. A compressor technology qualification program would be required, with no certainty of success, before centrifugal compressors could be used for the combined low flow and high pressure operating conditions. Even assuming this could be completed successfully, the time frame to complete this technology qualification program would prevent the Project from meeting its YE2014 start-up commitment.

In addition, there does not appear to be a clear advantage to either technology in terms of environmental impacts. In this regard, it is important to appreciate that either the selected reciprocal or potential centrifugal compressors would require the use of gas turbines, either to drive generators supplying power to the electric motors driving the reciprocating compressors, or to directly drive the centrifugal compressors. Thus, the overall air and noise emissions would likely be fundamentally comparable.

Comparison of Reciprocating Versus Centrifugal Compressors for the Point Thomson Project Injection Compressors

As noted above, both reciprocating and centrifugal compressors were carefully considered for the Point Thomson Project. This section provides a comparison of the two types of compressors in terms of proven technology, operating characteristics, and potential environmental impacts with respect to the proposed Project. These provide an understanding of the basis for selecting reciprocating units for Point Thomson. The primary reason for choosing reciprocating compressors for the Point Thomson Project was their proven capability to meet the required Project operating conditions as further explained below.

1. Importance of Proven Technology

A key requirement for the Point Thomson Project is to utilize proven technology wherever possible. This is critical for the following reasons:

- To achieve the objective of obtaining reservoir and facility performance data to facilitate appropriate process and equipment selection and design for any subsequent development phase
- To meet Project timeline requirements (technical design, permitting, and execution) for start-up by the end of 2014 and reliable operation for the life of the Project.
- High cost for re-design and retrofit after equipment is installed at a facility sited at a location that is severely challenged by logistics (remote, arctic such as Point Thomson) demands use of proven and robust designs and the need to minimize the technology step-outs wherever possible.

The elimination of technical risk is a key project objective given the large investment involved, particularly in a remote and hostile environment.

a. Reciprocal Compressors

The advantages for reciprocating compressors in this application include, but are not limited to, the following:

- Proven and available design at required operating conditions
- Availability of compressor units in the desired capacity range
- Flow rate insensitive to discharge pressure changes
- Ability to vary suction and discharge pressures over a range of operating conditions
- Less sensitive to changes in gas molecular weight and average gas properties
- Higher overall efficiency (especially at higher compression ratios)
- Lower discharge temperature due to higher efficiency and jacket cooling

b. Centrifugal Compressors

By contrast, centrifugal compressors do not constitute proven technology at the required operating conditions for the Point Thomson Project. The key disadvantages of centrifugal compressors for the Point Thomson Project include:

- Centrifugal compressors are not proven and there is no current design available at required operating conditions
    - It is impractical to rely upon a single compressor for a major operation such as Point Thomson, so it would be necessary to use multiple compressors (e.g., each capable of 100 million scfd) to meet the capacity requirements.
    - No manufacturer can respond (i.e., demonstrate) that they have a centrifugal compressor that has been designed, built and operated satisfactorily which meets, or is close to, the required flow rate and injection pressure (e.g., each compressor capable of 100 Million scfd) and 10,000 psi discharge pressure).

- The low flow rate and high discharge pressure results in no proven or available centrifugal compressor design. For example, the centrifugal compressors designed and operating on the Tengiz SGI project, which have been referenced in discussion with HDR, had a ~2.5X higher capacity. Larger compressors in the range of the application at Tengiz do not meet the Project's purpose and need.

- Even if a manufacturer claimed that a centrifugal compressor is available that might meet Point Thomson's need, a technology qualification process would be required and this would require 2+ years to be completed and a successful outcome could not be predetermined.
  - The use of centrifugal compressors at Point Thomson would require additional qualifications of technology to determine whether the design considerations listed below are adequately addressed:
    - Turndown / Operating range
    - Capacity control method
    - Surge control
    - Thermodynamic performance
    - Aero component experience
    - Rotating stall
    - Rotor dynamics / Fulton Diagram
    - Case discharge temp
    - Casing flanges size
    - Casing design (rating)
    - Impeller stresses
    - Impeller shrink fit stresses
    - Impeller torque transmission
    - Shaft end sealing
    - Journal bearing size
    - Shaft end coupling connections

- The uncertainty of the technology employed by centrifugal compression is not appropriate for application to a gas cycling project that has as much uncertainty in operating conditions as exists for the Point Thomson project
  - There is significant uncertainty in reservoir performance due to limited available reservoir performance and producing and injection test data.
  - There is significant uncertainty in high pressure gas/liquid separation performance

2. Point Thomson Project Operating Requirements

The Point Thomson Project will initially have a single production and a single injection well. Uncertainty and some variation in well production and injection performance is to be expected. In a development with a larger number of production and injection wells, the uncertainty and variation are more easily accommodated as the individual well performance is only a portion of

the total well flow. In that case, a change in a performance parameter (e.g. composition or injectivity) from one of a number of wells has a less significant impact to the parameter after mixing with other wells. A temporary or permanent decrease in injectivity for the single injection well at Point Thomson would have a direct proportional impact on facility production.

The compressors may be required to operate over a range of conditions due to:

- Variations in suction pressure resulting from high gas/liquid separation performance
- Variations in discharge pressure resulting from well injectivity performance. It should be noted that well injectivity can and does vary over time due to a number of factors.
- Variations in gas composition as a result of reservoir and production well performance

a. Variations in suction pressure

Peformance data for gas/liquid separation at planned Point Thomson operating pressures of 2700 psi does not exist. The facility may be required to lower the operating pressure of the separator to achieve the necessary liquids removal from the gas stream. Incomplete removal of liquids from gas will result in severe damage to a compressor. Alternatively, improved separator performance may be realized, and the operating pressure can be increased resulting in additional facility throughput capability. Suction pressures may vary from 2200 to 3000 psi depending on high pressure separation performance.

b. Variations in discharge pressure

The required discharge pressure is a function of the reservoir rock quality and the gas injection rate. For a given rock quality, higher injection rates require higher discharge pressures and lower rates can be accomplished with lower discharge pressures. Reciprocating compressors can take advantage of the lower discharge pressures and reduce the power demand while maintaining operating efficiency. Centrifugal compressors have a more narrow operating range and are designed to operate continuously at or near the maximum discharge pressure required, and may not be able to take advantage of lower than design injection pressures since their operating map is much more restricted. The parameters discussed in Section 2, (and others) in combination, are the operating conditions that a compressor must be designed to operate within and is called an operating map.

If the well injectivity is better than expected, the reciprocating compressors would operate at a reduced pressure thereby saving fuel and reducing maintenance. In this case, the centrifugal compressors would operate at the higher design pressure, consuming more fuel per unit of gas compressed.

If the well injectivity is worse than expected, then the required discharge pressure at a given injection rate will be higher. This would reduce the throughput on the centrifugal machine, impacting production. However, the reciprocating machines would be able to operate at somewhat higher injection pressures if the power is available. In this case, production would not be impacted.

Well injectivity has significant uncertainty as no injection test data are available. Data available include well logs, reservoir cores, and seismic surveys. These data highlight uncertainty in reservoir connectivity across the field, which could impact the ability to efficiently cycle gas between the producer and the injector. Analysis of the limited available data indicate that discharge pressures may vary from 9,500 to 10,500 psig.

c. Variations in gas composition (molecular weight)

Varying inlet composition is also a condition that favors the reciprocating compressor since this is a positive displacement machine meaning that a specific volume of gas is drawn into the compressor chamber where it is trapped, compressed and discharged. A centrifugal machine is a dynamic type of compressor where the increase in pressure is accomplished by dynamic (or motion related) energy from the rotor to the gas. For these dynamic machines, more head is required for low molecular weight gas than for a higher molecular weight gas.

Maintaining a narrow band on gas composition allows a centrifugal compressor to stay within its operating map. Changing the inlet composition by reducing the molecular weight requires more power for the same discharge pressure. Changes in gas molecular weight could arise from changes in reservoir composition over time and the result of varying the inlet separator pressure. A centrifugal machine will need to be designed and operated in this future mode so that it can cover the entire range over the operating life. As a result, the design flexibility is reduced, and it may be more difficult to accommodate the range in operating conditions. In fact, it may be necessary to design at the maximum anticipated discharge pressure for the lowest molecular weight gas. This would require that the unit initially operate in partial recycle during the early field life, impacting fuel efficiency and increasing air emissions.

Centrifugal compressors, being dynamic machines, have a much more restricted operating map than a reciprocating compressor. A centrifugal compressor must be operated within a "safe range" to prevent dynamic instabilities such as compressor "surge" and "stall" which have the potential to result in significant equipment damage. To prevent this, the systems use anti-surge devices to ensure that the machine always stays in the safe part of the operating map. This operating map does not always provide the design flexibility to vary the suction and discharge pressures.

For Point Thomson, the selected 2-stage reciprocating compressors offer a much wider operating map. If the discharge pressure is lower or higher than expected, the compressors have the flexibility to adapt to the change without compromising the operating integrity of the machines. In fact, since there are two stages, each with relatively low compression ratios, the cylinder size and inter-stage pressure can be re-configured to optimize the energy requirements and more closely fit the required operating conditions dictated by the reservoir and injection well performance.

3. Environmental Impacts

As noted above, while it is difficult to precisely compare characteristics of proven and available reciprocating compressors with those of potential centrifugal compressors which have not been designed, built and qualified, there does not appear to be a significant advantage to either compressor in terms of environmental impacts. Although the compressors have somewhat

different operating parameters and characteristics, because the power system would be the same in either application, there does not appear to be a significant difference in terms of noise or air emissions.

The centrifugal and injection compressors are not anticipated to be appreciably different in noise emissions (i.e. sound power level). In either case, the compressors are located within an enclosed building which provides a further limited noise abatement. The reciprocating machines do operate at a much lower speed than centrifugals and thus generate noise at a lower frequency which transmits farther distances and is harder to attenuate. However, the largest continuous noise contributors at the facility are the gas turbines providing power to the electric motors driving the compressors. The noise emissions from a gas turbine are in a lower frequency range and are similar to the reciprocating compressor. Their higher noise power levels will dominate the far field noise transmission and thereby mask the noise contribution from the reciprocating compressors. Also, gas turbines would be used to drive centrifugal compressors.

The power requirements would not be significantly different for reciprocating compressors versus the centrifugals, although probably higher for the centrifugal compressors due to the centrifugal's reduced design flexibility and resulting less efficient performance at non-design conditions. The project would likely incur increased fuel consumption and increased air emissions with centrifugals.

It is possible that a centrifugal compressor, depending upon qualification and actual design, might have a slightly smaller system footprint than using a reciprocating compressor. However, the reduced compressor footprint would be offset by increases in other system equipment and piping. This is because of the lower compression efficiency and resulting higher power requirements that transmits more heat into the gas thus increasing gas cooling duty (heat that must be released to the environment). However, any potential difference is unlikely to be significant on an overall project basis. For the Point Thomson Project, the Central Pad footprint is primarily dimensioned by the drilling rig, drilling support equipment, construction laydown area, camps, buildings and most importantly, the safety spacing between the processing modules and the high occupancy buildings (i.e. the operations camp and Central Control Room). As an example, a difference of 10,000 sf in the compression module translates into a 0.5% impact to a nominal 45 acre site.

4 Future Development

Full development and depletion of the Point Thomson reservoir could encompass a gas sales project or a future gas cycling phase(s). The use of reciprocating compressors for this Project will not affect or compromise the ability to use centrifugal compressors in any future development phase.

For a gas sales project, centrifugal compressors would likely be used as they are proven technology at the expected operating conditions for a gas sales project and the current Project will provide performance data to properly design centrifugal compressors.

For a future gas cycling expansion, the operating parameters that have a key impact on centrifugal compressor design may have been established with sufficient confidence to consider use of centrifugals. A key consideration for using centrifugal compression technology will be the

improved certainty regarding reservoir and high pressure separation performance obtained from the proposed project.

A future gas cycling expansion will likely entail larger design capacities to improve project viability. As discussed previously, larger flow rates favor centrifugal compressors. For any potential future development phase of the Project the centrifugal compressor industry will have had additional time to advance technology development and perhaps realize proven and available designs. If market forces have not led to a proven centrifugal compressor design that can meet Point Thomson requirements at that time, then a compressor technology qualification program would be necessary before centrifugal compressors could be considered.

Conclusion

For the Project design throughput and high operating pressures, and associated low flow rate, the only proven technology is the reciprocating compressor. In addition, the flexibility and range of operating conditions provided by reciprocating machines is much better suited to the Project, which may need to operate at conditions that vary from any fixed design point. This is due to the uncertainty of the reservoir performance, producing and re-injecting, reservoir performance under a gas cycling operation, and high pressure gas/liquid separation. Reciprocating compressors do not present unacceptable project risk, as do centrifugal compressors, and enable the project to meet the YE2014 production commitment

Centrifugal compressors do not meet Project practicability and purpose and need requirements because they are not proven, qualified or available with performance characteristics and size necessary for the Project as designed. In addition, in part because they would be driven by gas turbines, they do not provide any significant advantage in terms of environmental impacts.

ExxonMobil Technical Brief #3

Analysis of Proposed "Light Duty" Road

INTRODUCTION

The current road design for Point Thomson consists of a minimum 5-foot, non-insulated fill section with a driving surface width of 32 feet. Concepts to provide thinner and narrower roadway sections for the Point Thomson Project are examined in this document. The goal of the minimization is to provide reduced footprint on the natural tundra. The primary consideration related to reduced fill height relates to thermal issues and maintaining the frozen subgrade below the fill section, although vehicle loads also have an effect. Roadway width will primarily be controlled by operational issues. This document has been prepared to summarize general efforts associated with the design issues and does not include detailed analyses of the current project or presented concepts.

THICKNESS ANALYSIS

The absolute minimum thickness of gravel fill and insulation over the natural tundra in order to maintain thermal integrity is approximately 2.5 feet of insulated section (reference Figure 1). This thickness recommendation is based upon previous studies of determining the thickness of gravel required to maintain a frozen subgrade beneath the gravel fill. The thickness also requires thickening wherever culverts are required for established stream channels or for cross drainage. Typically, culverts will need to be placed at approximate 500-foot intervals, so this cover fill will likely result in a much thicker section in order to avoid severe vertical ups and downs within the road alignment.

The proposed minimum fill section for thermal considerations is shown below in Figure 1. Uninsulated gravel roads on the North Slope can typically experience a minor amount of thaw beneath the fill section during abnormally warm years without adverse impacts as long as the road is maintained. However, for the insulated, minimum fill section, it will be imperative that the subgrade is maintained in its frozen state. The integrity of the insulation must be maintained in order for the insulation to perform adequately. Differential settlement beneath the insulation, which could occur at polygonal ice wedges, could break and compromise the insulation. Considering these issues, it could also be expected that maintenance costs will be higher and there is potential for greater long-term environmental impact for insulated road sections, particularly at the edges where it is likely insulation will not hold up to the environment and degradation may occur.

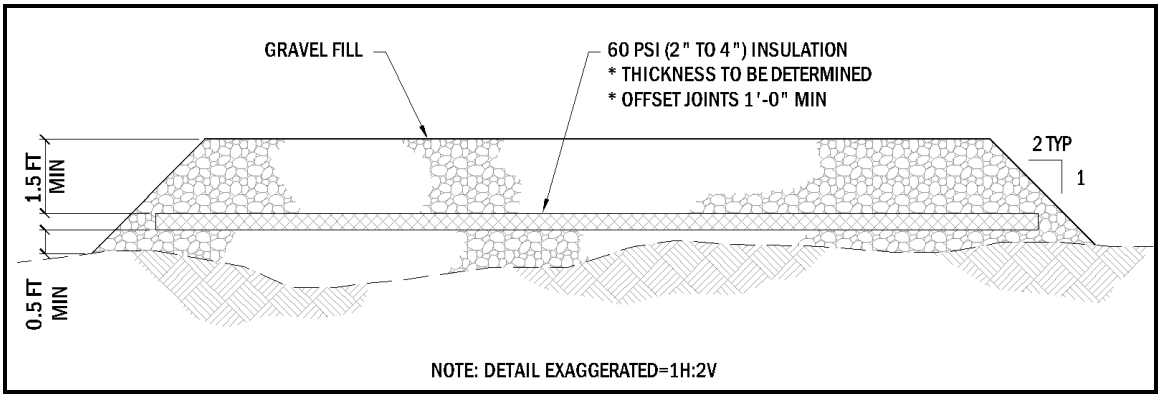

Figure 1 – Minimum Thickness Insulated Road Section

The minimum required road section at culverts is shown in Figures 2 and 3. Insulation must be placed above the culvert in order to position the culvert at grade, while maintaining the integrity of the tundra mat beneath the culvert and at the inlet/outlet. As previously mentioned, this thickened section will be required approximately every 500 feet (based upon historical construction) and would result in a "roller coaster" road alignment if the minimums are maintained. A typical minimum thickness road profile considering culverts spaced at 500 feet on center is depicted in Figure 4. This up and down road alignment is not conducive to efficient vehicular travel and a smoothed out road surface would be more desirable. It should also be noted that the section at culverts is very near the minimum uninsulated thickness of 5 feet for even the smallest proposed 24-inch culverts.

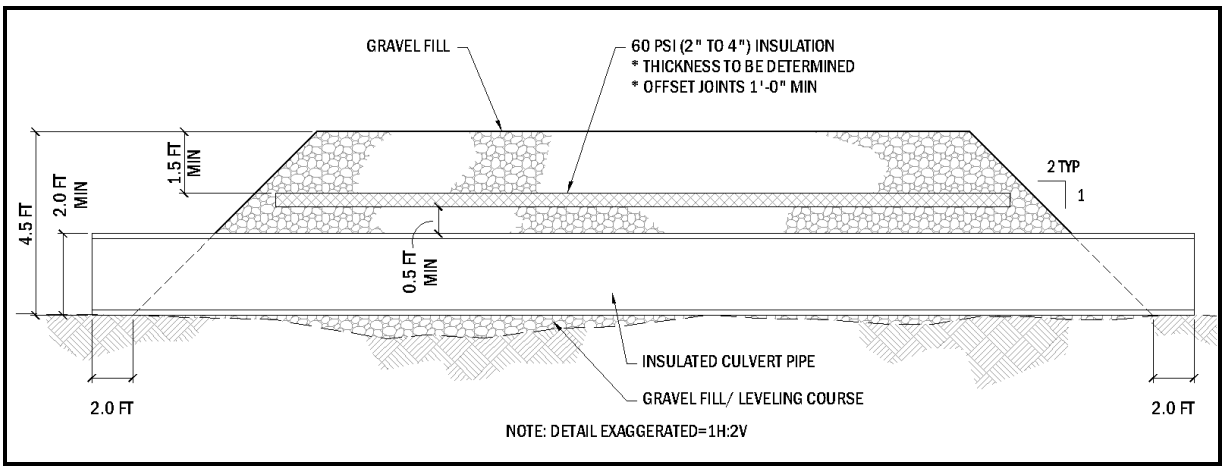

Figure 2 – Insulated Road Section at Culvert

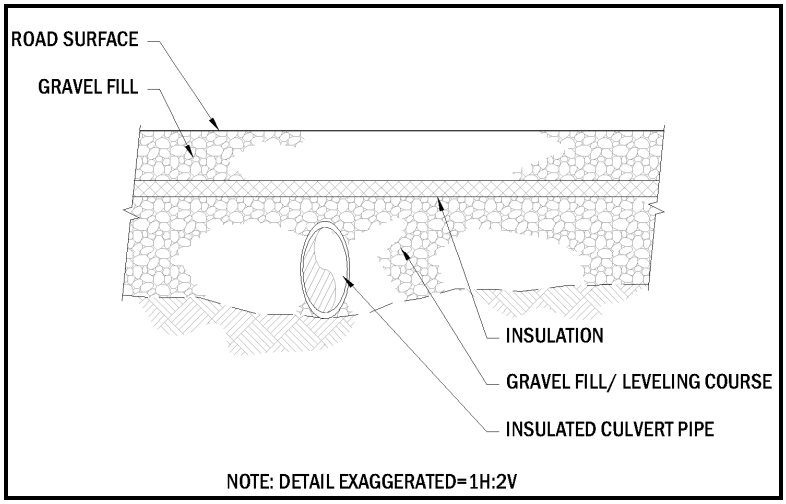

Figure 3 – Culvert Profile for Insulated Road

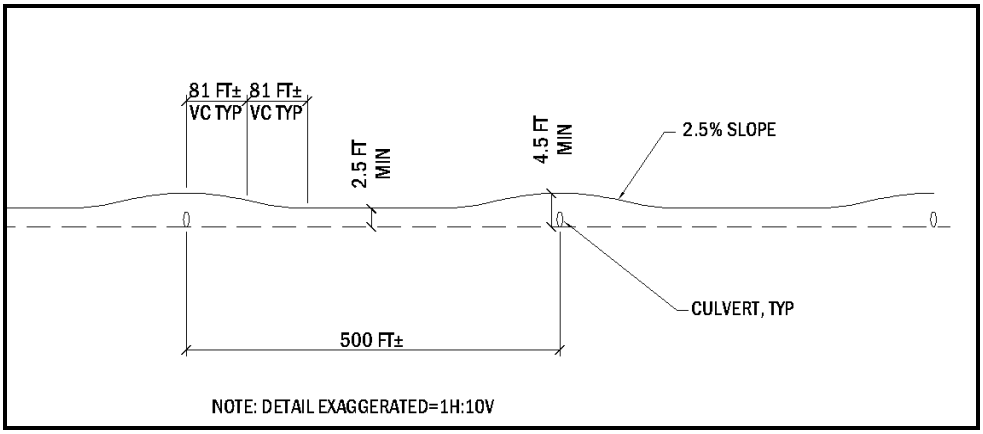

Figure 4 – Typical Insulated Road Profile

Gravel fill thickness was also reviewed considering the maximum anticipated vehicle loads on the road surface. The controlling detail with regard to vehicle loading is the pressure on the insulation. Excessive pressure from heavy vehicles could crush the insulation severely reducing the insulative values and resulting in thermal degradation. Minimum thicknesses for various vehicle loads are presented in Table 1.

Table 1 – Fill Thickness Requirements

Vehicle	Required Fill Thickness Over 60 psi Insulation Board
Standard Highway Truck	18 inches
Coil Tubing Unit / Vac Truck	25 inches
Drill Rig	64 inches

Insulation utilized in the analysis represents maximum strength practically available. Some manufacturers have advertised availability of insulation with 100 psi ultimate strength, but inquiries into availability indicate that the material is difficult to procure, requires the use of higher safety factors (thereby reducing the benefits of the higher strength) and is very costly. The 60 psi ultimate strength insulation represents the strongest practical alternative.

The required depth of fill depicted in Table 1 indicates that insulated road sections are not practical when utilized by drill rigs. The necessary depth of cover exceeds the standard uninsulated thickness of 5 feet. Additionally, the only vehicle loads acceptable for travel on the minimum sections identified above (2.5 feet nominal thickness with thicker sections at culverts) would be standard highway vehicles. Standard oil field vehicles, such as Vac trucks and coil tubing units would require approximately 6 inches greater thickness than the minimum.

WIDTH ANALYSIS

Road width can be reduced if access is limited to trucks and passenger vehicles (i.e. modules and drill rigs cannot utilize the gravel roadway). The absolute minimum recommended width for a single lane, one-way road is 18 feet. Many standard vehicles on the North Slope are 12 foot wide and, considering safety issues with maneuverability, blowing snow and low visibility, a 3-foot shoulder width is most applicable.

A single-lane road could have significant effect on operations and construction. Passing zones and pull outs would be required periodically to allow two-way traffic. 1,000-foot spacing is recommended for these pull outs unless procedures were implemented to coordinate the direction of traffic. Construction would be affected in that a separate ice road would be required for maneuverability of the gravel haul trucks. The narrow road width is not sufficient to allow for truck turnaround and, thus, a parallel ice road would be required to accommodate construction.

Alternatively, a narrower two-lane road could also be constructed if drill rig and module access were restricted. Standard lane widths for two-lane traffic are 12 feet, which would result in a total width of 24 feet. However, two lane roads are also normally constructed with shoulders, which would result in a total width of 28 feet.

CONCLUSION

The minimum thickness road profile, as depicted in Figure 4, is controlled by requirements to protect against thermal degradation and to provide cross drainage for surface water runoff. This alignment is not practical for vehicle use and the optimized smooth road surface results in minimal reduction of fill height (approximately 6 inches in lower road elevation) over the tops of the culverts. Although culverts will likely be at lower elevations and some benefit can be realized from this, the overall reduction in fill height is not likely to be more than 1.5 feet. Furthermore, the insulated section has much greater susceptibility to damage and degradation if warmer than expected temperatures occur, which would require greater safety margins in design development.

Road width can be reduced up to 18 feet with reduced operations capability. The minimum road width would provide single lane traffic and would not allow access by drill rigs or modules.

ExxonMobil Technical Brief #5

Buried Pipelines on the North Slope

Potential issues for buried pipelines on Alaska's North Slope

A number of significant issues must be addressed when designing, constructing, and operating belowground pipelines transporting warm fluids on the North Slope including:

- Thaw / differential settlement
- Impacts to surface drainage
- Thermokarsting
- Upheaval buckling
- Corrosion protection

All examples given in the following discussion are taken from information readily available in the public domain.

Thaw settlement

When ice-rich permafrost thaws, settlement occurs as the soils consolidate. The amount of soil consolidation depends on the soil type but is generally high for ice-rich silts, a common soil type on the North Slope. The resulting soil consolidation is known as thaw settlement and is most commonly associated with pipelines operating at temperatures above that of the surrounding soil which is the typical condition for pipelines operating in the gathering systems of the North Slope. Thaw settlement may also occur as the result of ponding, thermokarsting, or other surface disturbance that thaws the underlying permafrost.

Thaw settlement may result in significant differential movement of the pipe that can generate excessive stress and strains on the pipeline; this may cause failure of the pipeline.

Thaw settlement of the Trans Alaska Pipeline System's mainline has occurred in several locations and led to two pipeline failures shortly after start-up (http://www.alyeska-pipe.com/Pipelinefacts/Chronology.html). The Norman Wells Pipeline in Canada has also experienced thaw settlement (http://www.ogj.com/ogj/en-us/index/article-tools-template.articles.oil-gas-journal.volume-99.issue-20.transportation.permafrost-pipelining-1-northern-canadian-pipeline-deals-with-effects-of-soil-movement.html)

Thaw settlement of a portion of the Trans Alaska Pipeline System's Fuel Gas Line that runs from Pump Station 1 to Pump Station 4 was identified in 1985 (Alto and McDevitt 1989) and subsequently repaired. While this case did not result from burial of a heated pipeline, it points out that buried pipelines can be affected by thaw settlement caused by the presence of a nearby

road. The construction and presence of a road changed the natural thermal regimes of the soils and this combined with hydrologic and geotechnical factors, such as the depth of the active layer and presence of near surface ground water, to cause erosion and thaw settlement which in turn affected the fuel gas pipeline.

Impacts to surface drainage

Where buried lines cross a natural drainage it is important to ensure the drainage pattern is not changed resulting in diversion of water flow – either longitudinally or transversely to the pipeline. Should this occur the results may be significant erosion (both through hydraulic and thermal action on the surrounding soil), exposure of the line, or thawing of the soil supporting the pipeline.

All of these issues have been experienced on the Trans Alaska Pipeline System's Fuel Gas Line (Alto and McDevitt 1989).

Hydraulic and thermal erosion of the ground surface over or near the Badami pipelines river crossings has also been observed. At least one area was the result of impacts to surface drainage.

Thermokarsting

Thermokarst is a land surface characterized by very irregular surfaces of marshy hollows and small hummocks formed as ice-rich permafrost thaws. Surface disturbances caused by installation of a buried pipeline or thawing caused by the pipeline itself may lead to development of thermokarst, which in turn may lead to ponding of surface water. Ponding may lead to additional thawing and further subsidence.

Some of the issues observed on the Trans Alaska Pipeline System's Fuel Gas Line and the Badami pipelines river crossings may have been caused by thermokarsting.

Upheaval buckling

Upheaval buckling of buried pipelines normally occurs where the soils above the pipeline cannot provide sufficient restraint to prevent lateral buckling of the pipeline due to thermal expansion. This is a particular concern on buried pipelines installed in the winter when the soils being backfilled into the pipe ditch are frozen in non-cohesive segments, and/or mixed with snow and ice which may seriously impact the ability to achieve adequate compaction.

Similar to thaw settlement, upheaval buckling may result in significant differential movement of the pipe that can generate excessive stress and strains on the pipeline, which may cause failure of the pipeline.

Upheaval buckling has been observed on the Trans Alaska Pipeline System's Fuel Gas Line and the Norman Wells Pipeline.

Corrosion protection

Cathodic protection systems are typically required on buried pipelines. It has been noted that these systems do not function efficiently, if at all, in frozen ground, especially should the pipeline be insulated due to the high resistivity of frozen soils and the shielding offered by some insulation and coating systems.

External corrosion issues have been documented at cased crossings and other buried pipe locations operated by BP Exploration, Alaska (Coffman 2005). In 2004 BPXA conducted 623 inspections in 45 excavation sites on buried pipes in the Milne Point Unit (Coffman 2005).

Insulation integrity

Should insulation of the buried pipeline be required, a suitable waterproof barrier must be designed and installed. Water stops may be required at the end of the insulation to prevent water from migrating from a field joint into or under the insulation surrounding the pipe and degrading the thermal properties of the insulation or causing external corrosion of the pipe. The water stop may consist of a barrier sealed to both the pipe coating and waterproof barrier installed over the mainline insulation or an extension of the waterproof barrier over the end of the insulation where it would be sealed to the pipe coating.

Most corrosion of buried pipelines occurs at the field joints. Care must be taken to clean the pipeline prior to application of coatings to ensure proper adherence. Injection of a rigid elastomeric polyurethane insulation may be considered for filling joint cavity. Particular attention must be given to ensure that the waterproof jacket (e.g., heat shrink sleeve) around the field joint properly adheres and seals to the adjacent waterproof barrier to ensure water tightness. A waterproof tape should not be used at the field joints due to probable water leakage at the seams.

Monitoring, Maintenance, and Repair Considerations

Access and logistics for both planned and unplanned maintenance of a buried pipeline on the North Slope can be somewhat problematic particularly due to the need to excavate the soil over and around the pipe.

Where there is no access road, access for maintenance of a buried pipeline would typically be facilitated in the winter using ice roads. Winter repairs can be successfully completed with the use of conventional types of equipment used for pipeline construction along with low ground pressure transportation vehicles. The use of low ground pressure vehicles on frozen ground would eliminate the need for an ice or snow road.

The summer, however, offers generally better and safer work conditions and higher production rates for hand labor around pipelines. Ground travel in summer can only be used for short distances and only when other options are not available. Tundra that is traversed using tracked

or low impact rubber tired equipment may require remedial work upon completion of the repair. Also, access permits may not allow summer ground travel.

In general, any work done on a buried pipeline in the summer would likely require equipment and manpower to be transported by helicopter or low ground pressure equipment. Equipment such as backhoes and bulldozers must be small enough that they can be easily broken down, transported to the site, and reassembled.

The pipelines will be equipped with a leak detection system that will alert operators in cases where anomalous pipeline pressure changes reach the detection threshold. However, these systems are not failsafe; visual monitoring of pipelines on VSMs provides the advantage of a second means to monitor and discover pipeline leaks. Should a pipeline leak occur, the amount of oil that leaks from a buried pipeline could be much larger than from an aboveground pipeline depending on the leak rate and detection time.

Summary

Documented information on warm pipelines buried in ice rich permafrost clearly shows that thawing and settlement can occur. Insulation slows, but does not stop heat transfer to surrounding soils and these soils, if not thaw stable, will experience settlement. Geotechnical considerations identified in this brief are additional considerations that can affect pipeline integrity. All these issues, individually or collectively, pose potential increases in operating risk, especially over the long term life of the pipelines.

ExxonMobil Technical Brief #6

Point Thomson Runway Design

The Point Thomson airstrip consists of a 5000’ x 150’ gravel runway, with additional 25’ shoulders and 300’ safety zones at either end of the runway. The total gravel footprint of the airstrip is 5600’ x 200’.

This runway length and the runway shoulder dimensions are governed by the requirements of the expected Lockheed L-100 (382) Hercules cargo aircraft operator, Lynden Air Cargo. Runway width is determined by the FAA recommendations for the Hercules and similar size aircraft.

The runway safety areas provide support for aircraft and rescue equipment in the event of a short landing or an aircraft overrun. These safety areas follow FAA standards for the aircraft that are expected to be routinely transporting personnel to and from the facility (airframes smaller than the Hercules). In addition to the identified safety areas at the runway ends, the FAA also specifies a safety area width standard of 150’ (centered along the length of the runway) for routine air traffic; the project is exceeding this standard by using the criteria for the Hercules noted above. Potential routine air traffic consists of de Havilland Twin Otters, Beech 1900D Airliners, or other similar aircraft.

The attached drawings show the runway and safety areas, and runway lengths specified for airframes that are planned to provide service to the Project.

ExxonMobil Technical Brief #7

Buried Pipelines in Gravel Roads on the North Slope

Introduction

The main risks with installation of a buried pipeline in the Arctic flowing warm product within or beneath a road are similar to those associated with buried pipelines in the tundra (see ExxonMobil Technical Brief #5). One quote from an Alyeska paper on the integrity of belowground segments of TAPS following the 2002 Denali Fault earthquake summarizes the effects of buried pipelines on the permafrost and is referenced at the end of this Technical Brief. The complete paper is also attached. The paper notes that "except for a relatively short (6-km) portion of the buried pipeline where a specially insulated and refrigerated system keeps the foundation frozen" the warm buried pipeline thawed most permafrost along the right-of-way (where permafrost was initially present within 35-50 m below pipe). The problems experienced by Alyeska would expect to be more significant at Point Thomson where permafrost is present to within 1 m of the surface.

The decision to bury warm pipelines in frozen ground must be made on a case-by-case basis with consideration of local environmental conditions, permitting requirements and constructability and operational considerations. Generally, it is a technically feasible option only after investigation of the thaw stability and frozen state of the subsurface soil, accompanied with an estimation of the effect of operational conditions on these in-situ conditions during the design life.

The soils in the Point Thomson area are ice rich and thaw stability with a warm pipeline is very unlikely. Insulation of the buried pipelines may prove effective in limiting the thaw to acceptable limits, although ensuring the long-term effectiveness of buried insulation is problematic. If insulation alone is not capable of preventing thaw, a refrigeration system along the pipeline would be required.

Potential issues for buried pipelines on gravel roads on Alaska's North Slope

While it is known that at least a few pipelines on the North Slope have been installed within or beneath roads, detailed information within the public domain was unable to be located. Risks are further increased due to the possible loss of soil cover above the pipe during normal road usage and road maintenance activities. Loss of cover may expose the pipe to vehicular damage or reduce the capability of the surrounding soils to restrain pipe movement resulting in upheaval or lateral buckling of the pipe. In summary, the issues that must be addressed are:

- Thaw settlement resulting in detrimental differential movement of the pipe

- Upheaval or lateral buckling of the pipe due to insufficient soil restraint
- Corrosion protection (due to increased potential for moisture to migrate under pipe insulation and its protective jacket)
- Corrosion monitoring due to limited ability to access pipe for external inspections
- Mechanical damage due to vehicles

There are two main concepts for burying pipelines within or beneath a road:

- Bury the pipeline within the road prism. Here the pipelines are above the tundra but contained within the road prism. Mechanical damage from vehicular traffic is a major concern, and sufficient cover over the pipe must be maintained. Culvert installation becomes problematic with pipelines in the road prism.
- Bury the pipeline below the road prism. Here the pipeline is trenched into the tundra and a gravel road is constructed over the top. Danger from vehicular traffic is reduced and issues with cross drainage culverts are not as problematic. Thermal stability of the permafrost is difficult to maintain with warm pipelines. Thawing of the permafrost causes instability of the pipeline foundation. Typical fine grained North Slope soils are prone to thawing problems and the ice rich soils found at Point Thomson are especially prone. Pipe and possible ditch insulation / refrigeration requirements will be challenging compared to the in-the-road-prism concept.

Design Considerations

Design of pipelines buried within the prism or below the prism of a gravel road must consider:

- Heat transfer from the pipeline into the surrounding environment;
- The potential for thermal buckling and the corresponding civil design of the gravel fill with respect to compaction and restraint of pipeline movement;
- Protection of the pipelines, pipeline insulation, and waterproof jackets from damage due to vehicular traffic;
- Corrosion protection with special consideration given to the relative ineffectiveness of cathodic protection on buried insulated pipelines;
- Monitoring for pipeline corrosion, position and geometry defects over the life of the project;
- Road maintenance with periodic surveys to assess the relative orientation of the pipelines within the road prism to ensure the prescribed fill contours are maintained to protect and restrain the pipelines; and

- Leak detection and regulatory compliance.

To ensure an acceptable design for a buried pipeline the following items would be required during design:

- Geotechnical Program - A thorough investigation will be required to provide geotechnical soil properties and thermal regime properties.
- Geothermal Criteria - Geothermal modeling will be required to ensure configurations are stable for (1) historic and projected climate conditions and (2) the range of expected pipe insulation properties and operating conditions. An additional focus must be placed where culverts are placed through the roadway.
- Pipe Stress - A number of design considerations for buried pipelines are not applicable to aboveground pipelines and vice versa. Considerations include: overburden loads; surface loads; relative pipe-soil displacement; and upheaval buckling.
- Mechanical-Thermal Interaction – The pipeline operational thermal loads due to high operating conditions must be considered, especially in conjunction with potentially low installation temperatures. Buried pipelines must accommodate these loads by developing sufficient frictional resistance between the surrounding soil and the pipe to restrain thermal growth which results in an axial compressive force within the pipe. If not adequately restrained through placement and compaction of sufficient fill, the pipe will undergo Euler buckling (typically upheaval buckling since resistance in the upward direction is normally lower than the other directions). Alternatively, if combined stresses due to higher than normal axial compressive stress exceed allowables, belowground expansion loops will be required. The use of belowground expansion loops is rare in the industry and they would require large buried vaults. These would need to be sealed from near surface water intrusion, a very difficult design feature given the need for axial pipe expansion into the vault.
- Erosion Control - Sediment production, transport, and deposition related to pipeline construction must be minimized. Disturbance of natural drainage and thawing effects on permafrost caused by ponding or flowing water must also be minimized. Flowing water in the pipe trench, especially the first year of operation can cause issues with pipe stability.
- Pipeline Insulation and Field Joints - Insulation of buried pipelines must be carefully considered as without insulation the pipeline will thaw surrounding soils. Thawing of ice-rich soils must be minimized to prevent excessive settlement of the pipeline. However, insulation properties are severely impacted should water saturate the insulation.

Maintaining the integrity of any waterproof barrier, especially at field joints, is always an issue with buried insulated pipelines.

- Culvert Crossings - Drainage structures are typically installed periodically beneath roads to accommodate cross flow of water. Consideration of these structures must be included in the design to ensure adequate vertical separation from the pipe and to ensure adequate cover depth is maintained over the pipe. Construction installation methods will also need to be considered.

Operational Considerations

Operational considerations that may be required to ensure localized conditions are maintained to design limits include:

- External Corrosion - Use of external coatings and cathodic protection systems will be required. Effectiveness of cathodic protection systems is inhibited, if not effectively blocked or shielded by pipe insulation and its protective jacket.
- Pipeline Monitoring - In addition to the typical monitoring performed on aboveground pipelines, buried lines will likely require position monitoring via inertial measurement using in-line inspection tools to detect pipeline displacements caused by thaw settlement or Euler buckling. Results of inertial position monitoring would be compared with road surface surveys to ensure adequate cover depth is maintained as road maintenance may tend to remove fill over the pipeline. In addition, ground temperature monitoring to verify that ice-rich soils beneath the pipeline remain frozen should be conducted.
- Leak Detection - Leak detection can be accomplished via internal or external methods. Internal methods are essentially the same as those implemented for aboveground pipelines though without the added benefit of routine visual surveillance. External methods include vapor-permeable diffusion systems, electrochemical sensing systems, and optical fiber systems.

Maintenance and Repair Considerations

Maintenance and repair issues associated with a warm, buried pipeline in an arctic environment include:

- Thaw Settlement Remediation - When ice-rich soils beneath a warm pipeline thaw, settlement will occur and may result in excessive strains in the pipe, which may in turn require remediation to relieve the strains and return the pipeline to its original orientation.
- Excavation - a buried pipeline will likely need to be periodically exposed to perform detailed inspections, to repair defects or damage, or to relieve strains. Prior to

excavation, detailed analysis of the pipeline should be conducted to ensure the length exposed will not cause excessive pipe strains or deformations.

- Maintenance of Gravel Roads Containing Buried Pipelines - The gravel road in which pipelines are buried serves to restrain the pipelines from thermal buckling and protects the exterior of the pipelines from damage. The pipelines and the roads in which they are buried are considered as a single system and operated accordingly. Proper road construction and maintenance is crucial to ensure the long-term integrity of the pipelines.

ASSESSMENT OF THE BELOW-GROUND TRANS-ALASKA PIPELINE FOLLOWING THE MAGNITUDE 7.9 DENALI FAULT EARTHQUAKE

Elden R. Johnson[1], Michael C. Metz[2] and David A. Hackney[3]

Approximately 75 percent of the 1,287 km TAPS route was originally underlain by permafrost, necessitating a unique above-ground design in many places to accommodate potentially unstable, ice-rich permafrost conditions. Over one-half the pipeline (676 km) is constructed above ground, with the remainder (611 km) buried. The below-ground pipeline is, for the most part, a conventional buried design used in thawed soils and in permafrost that is defined as thaw stable (less than 6 percent fine grained soil). However, TAPS unique terrain and seismicity conditions required two additional options – a deep burial mode for use below unstable surficial soils, and a refrigerated insulated burial mode for use in thick non-thaw stable soils. As expected, the warm buried pipeline has thawed most permafrost along the right-of-way (where permafrost was initially present within 35-50 m below pipe), except for a relatively short (6-km) portion of the buried pipeline where a specially insulated and refrigerated system keeps the foundation frozen.

ASSESSMENT OF THE BELOW-GROUND TRANS-ALASKA PIPELINE FOLLOWING THE MAGNITUDE 7.9 DENALI FAULT EARTHQUAKE

Elden R. Johnson[1], Michael C. Metz[2] and David A. Hackney[3]

Abstract

Nearly half of the 800-mile (1,287-km) Trans-Alaska Pipeline System (TAPS) is buried in a standard pipeline trench with a minimum depth of cover of 0.9 m (3 feet). The magnitude 7.9 Denali Fault earthquake produced peak ground motions of 0.34 g at a location 5 km from the fault. The duration of shaking was approximately 90 seconds, contributing to liquefaction of subsurface deposits along the pipeline as evident from numerous sand boils. In some areas in proximity to the Denali Fault crossing, moderate lateral spread movements occurred. Landsliding did not occur along or across the pipeline right-of-way itself, although there were a number of landslides and rock falls that occurred proximate to the Denali Fault zone several tens of kilometers west of the pipeline.

The near-source violent motions coupled with soil liquefaction provided the opportunity for developing significant bending and axial strain in the buried pipeline. The pipeline was excavated at a location where evidence suggested lateral spreading or subsidence due to liquefaction, but no damage to the pipe was observed. Approximately one month after the earthquake, the pipeline was inspected using an instrumented in-line monitoring device ("smart pig") capable of detecting pipeline curvature and deformation. No evidence of pipe deformation, strain increases, or curvature changes in excess of acceptable limits were observed.

This paper provides an overview of the field reconnaissance of the below-ground pipeline segments in proximity to the Denali Fault, observations of liquefaction and ground failure, and a discussion of the use of an instrumented pig to validate pipeline structural integrity.

Introduction

The Trans Alaska Pipeline System (TAPS) zigzags off the North Slope in its unique above-ground configuration, transecting the State of Alaska 1,287 km (800 miles), south to its marine terminal in Valdez (Figure 1). At peak throughput, the 1,219-mm (48-inch) diameter pipeline transported 2.1 million barrels[4] per day (mbpd) of warm North Slope crude oil. Due to declining North Slope production, it currently delivers about 1.0 mbpd, or about 16 percent of America's domestic supply. The pipeline has

[4] One barrel equals 42 gallons.

been operated by Alyeska Pipeline Service Company (Alyeska) for its owners since startup in 1977.

On November 3, 2002 the Denali Fault, which intersects the pipeline route at Milepost 588 in central Alaska, ruptured over a distance of 336 km, producing the largest earthquake from a continental strike-slip fault in the United States since the 1906 San Francisco earthquake. This paper describes the design and performance of buried portions of TAPS near the fault during the magnitude 7.9 Denali Fault event. The above-ground pipeline design and its performance during the Denali Earthquake are described in a paper by Sorensen, et al. (2003).

TAPS Design

TAPS traverses a wide range of geotechnical conditions that directly affect design and operation of the pipeline and related facilities. The goal of the original geotechnical design was to provide a stable foundation for pipeline elements under both static and dynamic conditions. The pipeline design was affected by the extreme seismicity of Alaska, acknowledging that the magnitude 9.2 Prince William Sound subduction zone earthquake of 1964 remains the second largest earthquake ever recorded worldwide. Prior to construction, Alyeska conducted extensive seismological and engineering studies (Cluff et al 2003) to characterize active subduction zone and continental faults crossing the pipeline, develop ground motion design criteria, and mitigate the potential affects of geohazards such as soil liquefaction and landslides.

Three potentially active faults that crossed the pipeline in central Alaska were identified and fault studies were carried out to characterize fault length, expected rupture slip, fault zone width, and slip recurrence interval. Large rupture displacements up to 6m/1.5m (strike/dip) were anticipated on the Denali Fault, with 4m/3m on the McGinnis Glacier, and 2m/5m on the Donnelly Dome Fault.

Approximately 75 percent of the 1,287 km TAPS route was originally underlain by permafrost, necessitating a unique above-ground design in many places to accommodate potentially unstable, ice-rich permafrost conditions. Over one-half the pipeline (676 km) is constructed above ground, with the remainder (611 km) buried. The below-ground pipeline is, for the most part, a conventional buried design used in thawed soils and in permafrost that is defined as thaw stable (less than 6 percent fine grained soil). However, TAPS unique terrain and seismicity conditions required two additional options – a deep burial mode for use below unstable surficial soils, and a refrigerated insulated burial mode for use in thick non-thaw stable soils. As expected, the warm buried pipeline has thawed most permafrost along the right-of-way (where permafrost was initially present within 35-50 m below pipe), except for a relatively short (6-km) portion of the buried pipeline where a specially insulated and refrigerated system keeps the foundation frozen.

During the development of the design concept for TAPS, it was presumed that a buried construction mode would be incapable of withstanding the large ground

ruptures that might occur at the three identified active fault crossings. Hence, all known active faults were crossed above-ground (Sorensen et al., 2003; Hall et al., 2003). As an additional design safeguard, the standard trench design was validated for a generic condition of 0.6 m (2 ft) of differential movement due to ground rupture.

Seismic design ground motions for the Trans-Alaska Pipeline System are based on stipulated design earthquakes for five seismic zones along the route as delineated by the U.S. Geological Survey (USGS) (Cluff et al., 2003). A maximum credible earthquake, with an estimated return period of 300 years or more, was specified for each of the five seismic zones and defined in terms of Richter magnitude (used at the time of pipeline design) as depicted in Figure 1. Alyeska established design ground motions for earthquakes in each seismic zone as delineated in Table 1.

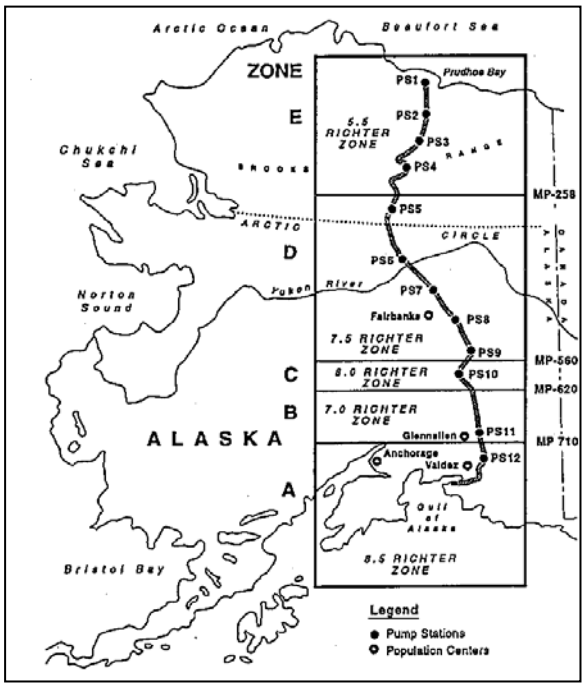

Figure 1. Seismic zones along the Trans-Alaska Pipeline

Table 1. Free Field Design Ground Motions

Seismic Zone according to Pipeline Milepost	Acceleration (g)	Velocity (cm/sec)
0 – 258	.12	15
258 – 560	.45	56
560 – 620	.60	74
620 – 710	.30	36
710 – 800	.60	74

November 3, 2002 Magnitude 7.9 Event

The Denali Fault ruptured over a distance of nearly 350 km. The epicenter occurred near the newly discovered Susitna Glacier thrust fault, approximately 90 km to the west of the pipeline. The fault intersects the TAPS route at Milepost 588 in central Alaska. Slip on the fault was measured at 5.5 m near the pipeline crossing with maximum slip of almost 9 m occurring 120 km to the east of the pipeline crossing.

Ground Motion during the Nov 3 event was recorded by Digital Strong Motion Accelerograph (DSMA) units maintained by Alyeska at Pump Stations 7, 8, 9, 10, 11,

and 12 as part of its Earthquake Monitoring System (EMS). Peak ground acceleration measured at these stations is given in Table 2. The highest ground motions were recorded at Pump Station 10, 5 km north of the Denali Fault. Maximum measured peak ground acceleration was 0.34 g, and a maximum ground velocity of 114 cm/sec (45 in/sec) was computed from the acceleration record. Considering that the acceleration signal was high-pass filtered at 0.1 Hz, the maximum ground velocity actually may have been about 50 percent higher than the value computed from the accelerograms[5].

At Pump Station 11, 155 km south of the Denali Fault pipeline crossing, measured peak ground acceleration was about 0.1 g whereas at Pump Station 9, 64 km to the north, the measured peak ground acceleration was about 0.08 g. Measured horizontal and vertical ground accelerations were less than design ground accelerations at all measurement stations, but the peak ground velocity was three to five times higher than would normally be associated with this level of acceleration due to the near-source violent ground motions associated with fault rupture.

Table 2. Peak Ground Accelerations vs. Design Accelerations

Pump Station	Pipeline Milepost	Measured Peak Accel.		Design Accel.

PS 12	735	0.039	0.024	0.600	0.400

Below-ground Pipeline Design and Performance

The below-ground pipeline design and operation considers the affects of a number of geohazards including thaw induced subsidence, landslides, soil liquefaction, fault movement, and axial strain associated with seismic wave propagation. Subsidence caused by thawing permafrost was the key factor influencing the TAPS below-ground design, and while not directly related to seismic aspects of design per se, it precipitated the development and use of in-line inspection technology that proved very effective in post-earthquake damage assessment of the buried pipeline.

Since 1992 Alyeska has used an inertial navigation inline inspection device ("smart pig") to obtain measurements that can be used to detect pipe deformation and other conditions that approach operational tolerance limits (Figure 2). The pig uses three-axis gyroscopes and accelerometers to determine the position of the pig in three-

[5] The maximum computed velocity is affected by high-pass filtering at 0.1 Hz. Based on preliminary results from in-progress studies conducted by the USGS, it is believed that the actual peak velocity could have been about 50 percent higher than the calculated value of 114 cm/sec, i.e., about 170 cm/sec.

dimensional space, and thus the pipe at 5-cm intervals along the pipeline. This position data is post-processed to calculate bending radius and bending strain. The pig also uses 64 radius-measuring fingers to determine circumferential deformation.

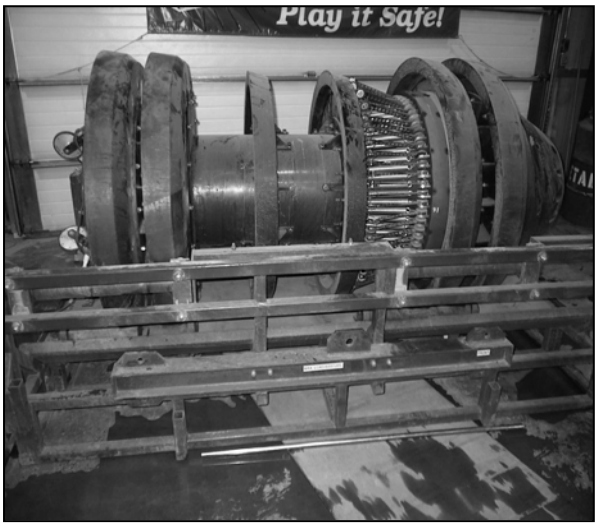

Figure 2. Inertial navigation tool used to determine pipeline curvature and deformation

Slope Stability

The federal and state Right of Way Agreements stipulated that unstable slopes shall be avoided, or where not possible, the design shall mitigate "harmful effects". Alyeska slope stability evaluations considered all types of soil mass movement including liquefaction. Near the Denali Fault, the pipeline design avoids potentially unstable slopes. Field surveillance was initiated immediately following the November 3rd earthquake. No evidence of slope instability affecting the pipeline was observed. Shallow soil detachments on ridge crests and rockfall and raveling on talus slopes was noted in the vicinity of the pipeline corridor, but these were too distant from the pipeline to constitute a threat. Significant (massive) landslides were noted by USGS observers where the fault zone parallels the Black Rapids Glacier, but these areas were several tens of kilometers to the west of the pipeline route.

Soil Liquefaction

Seismic liquefaction describes the behavior of certain cohesionless soils which, under saturated conditions, may lose a large portion of their shear strength as a result of earthquake shaking and may acquire characteristics of a viscous liquid mass with flow capabilities. The potential for soil liquefaction during a seismic event was one of the most important considerations in the design of the pipeline. Approximately 160 km (100 miles) of the below-ground pipeline is located in areas that were judged to be potentially liquefiable.

A pipeline buried in level ground subjected to liquefaction will tend to "float" or "sink" depending on buoyancy considerations. Lost ground associated with sand boils can also contribute to subsidence. When liquefaction occurs in a soil mass not confined by adjoining stable soil strata, lateral sliding or motion in the unconfined direction may occur.

For potential liquefaction areas that could not be avoided in construction, design mitigation measures were employed to assure long-term integrity for the pipeline. For below-ground sections of the pipeline, the most common mitigation is burial

below the potentially liquefiable soils. Other buried pipeline mitigations include grading of slopes to less than 2 percent, removal and replacement of potentially liquefiable soils and, special design with insulated pipe and heat pipes (thermo-siphons). On flat ground (less than 2 percent grade) no protective measures were required, but buoyancy of buried pipe sections was considered in the design.

Field inspection after the November 3 earthquake showed liquefaction events in high groundwater areas of floodplains, especially in the Delta River and Phelan Creek areas up to 30 km south of the Denali Fault. All of the observed liquefaction events are in relatively flat areas (less than two percent grade) with shallow groundwater conditions. Four locations were observed with a length totaling about 2 km (Table 3).

Table 3. Areas of Observed Soil Liquefaction

Location (Milepost)	Length, m	Slope
590.7 – 591.1	640	<2 percent
592.7 – 592.9	320	<2 percent
599.4 – 599.6	320	<2 percent
606.4 – 606.8	640	<2 percent

Observed liquefaction events resulted in sand boils, surface cracking with liquefied soil flow, and surface cracking resulting from lateral spreading of surface fill. Figures 3 and 4 show typical liquefaction sites in the Delta River floodplain south of the Denali Fault.

Ground cracking occurred parallel to the sides of the original pipeline ditch where select clean backfill surrounds the pipe. No ground cracking was observed over the pipe. Liquefied soils are thought to have used these parallel cracks as an avenue for escape, causing sand boils at the ground surface (Figure 5).

Figure 3. Surface evidence of liquefaction near Remote Gate Valve 91. south of Denali Fault.

Figure 4. Surface evidence of liquefaction in the Delta River floodplain.

Fault Movement

As mentioned earlier, the Denali Fault was crossed in an above-ground mode. Thus, the Denali Fault rupture did not affect the buried pipeline in a direct sense, i.e., due to abrupt surface offset and localized ground deformation in close proximity (100 m) to the rupture. The response of the above-ground fault crossing is discussed by Sorensen and Meyer (2003).

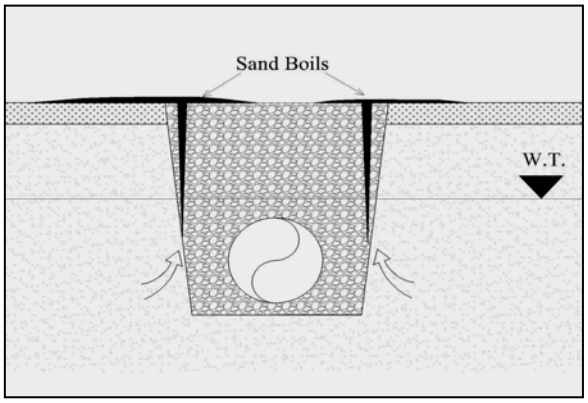

Figure 5. Diagram of typical liquefaction event

Surface Wave Propagation

A pipeline buried in soil that is subject to the passage of seismic waves (compression, shear and surface waves) will incur longitudinal and bending strains as it conforms to the associated ground strains. In most cases, these strains are relatively small, and welded pipelines in good condition, which is the case with TAPS, typically do not incur damage.

A relatively simple method to estimate axial ground strain from wave propagation is based on an approach developed by Newmark (1968) can be used to obtain an upper-bound estimate of ground strain due to a propagating seismic wave with a constant shape (sine wave). The maximum axial ground strain, ε_g, is given by:

$$\varepsilon_g = \frac{V_{\max}}{\alpha_\varepsilon c} \tag{5}$$

where V_{max} is the maximum horizontal ground velocity in the direction of wave propagation, c is the apparent propagation speed of seismic wave, i.e., the component of wave speed parallel to the pipeline under consideration, and α_ε is the ground strain coefficient corresponding to the most critical angle of incidence and type of seismic wave and ranges from 1.0 for compression and Raleigh waves to 2.0 for shear waves (ASCE, 1984). Estimates of wave travel speeds have not been made for the Denali Fault area, at least not by the authors; however, an apparent propagation velocity of 900 m/sec can generally be taken as a lower bound estimate (ASCE, 1984) to provide a maximum estimate of ground strain from body waves.

Assuming a maximum ground velocity of 170 cm/sec, a propagation speed of 900 m/sec, and a ground strain coefficient of 1.0, the maximum ground strain, , is 0.187 percent. If there is no slippage of the pipeline relative to the surrounding soil, then the maximum axial strain in the pipeline can be taken equal to maximum ground strain, an upper-bound, conservative assumption. However, if it is assumed that 100 percent of the ground strain is transferred to the buried pipeline, this would relate to a pipe stress of 387 MPa (56 ksi), which is about 85 percent of the specified minimum yield stress for Grade X65 steel pipe, well within elastic limits for buried pipe.

Ground curvature resulting from wave propagation will also induce bending in a buried pipeline, but the resulting pipe strains are generally so small compared to the direct axial strain effect that they can be neglected.

Curvature/Deformation Pig Results

The buried pipeline, located outside the fault zone, is typically less vulnerable to seismic hazards than the above-ground design. Hidden damage to the buried pipeline however, could not be visually inspected and, thus, required use of in-line inspection (ILI) methods (Figure 2).

Immediately after the occurrence of the Earthquake, planning began for the running of a smart pig. Before the pig could be run, it was necessary to run five cleaning pigs through the line to assure it was clear of wax accumulation which could affect the instrumented pig readings. Two of these cleaning pigs had a greater hard diameter thereby assuring clear passage for the smart pig. Following the smart pig run, the measurement data acquired between Pump Stations 9 and 11 was processed and reviewed to assess pipeline integrity. This covered a pipeline distance of approximately 220 km (137 miles).

If the pipe were to change position as a result of the earthquake, the change would first be apparent in the strain or curvature data. The software allows data from one year to be subtracted another and thus differences in values other than zero indicate a change. Example output from the smart pig run is shown in Figure 6. Changes were noted in the below-ground pipe in the area of Remote Gate Valve 91 (RGV91) and other areas with observed surface disturbance. Interestingly, in each case the change

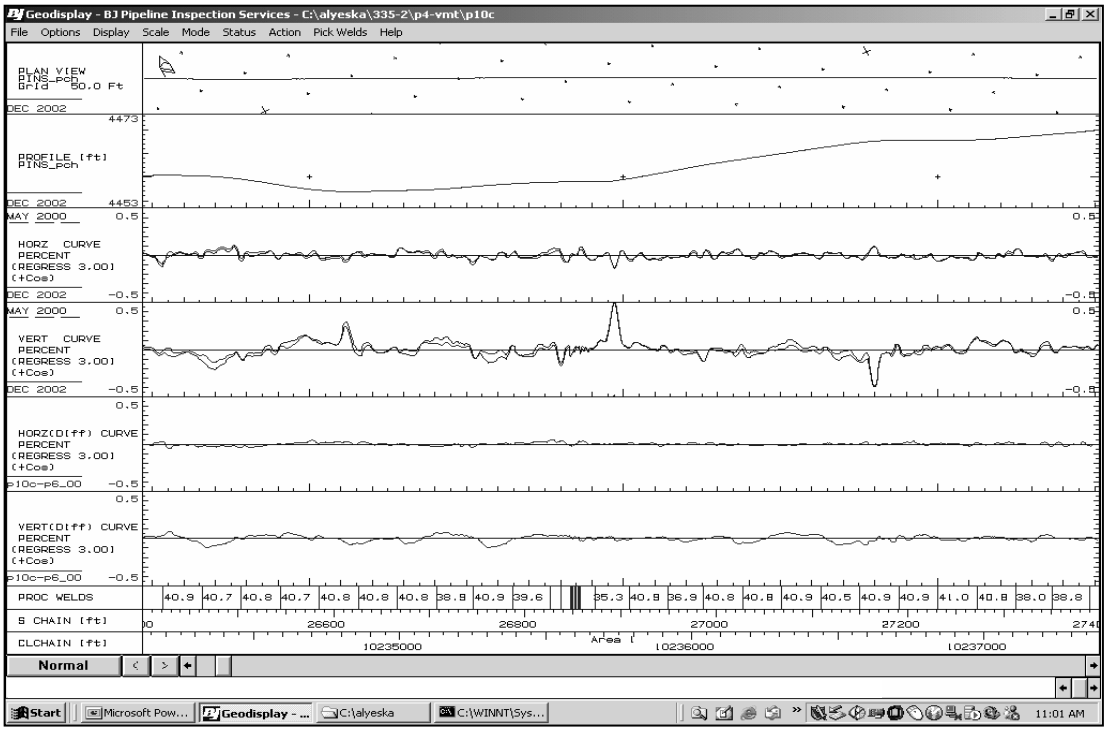

Figure 6. Smart pig data

was to a lower strain level. For example, one area north of RGV91 experienced a curvature change from 60 to 41 percent of critical bending curvature. Another area south of RGV91 experienced a curvature change from 56 to 34 percent of critical bending curvature. Both these areas demonstrated some indication of liquefaction, which apparently allowed the pipe to relax in the ditch during the shaking. Between Pump Station 9 and Pump Station 11 there are 15 dents and 18 other target areas of known bending curvature. Each of these locations were checked and found not to have changed as a result of the earthquake.

Summary of Observations and Findings

The buried pipeline met all performance expectations associated with the magnitude 7.9 earthquake of Nov 3, 2002. This section summarizes some of the key observations and findings.

1. Ground motions of 0.34 g maximum acceleration, velocities perhaps as much as 170 cm/sec, and a ground shaking duration of 90 seconds caused liquefaction to occur in loose, saturated cohesionless soils. A design strategy of crossing potentially liquefiable areas either on essentially flat terrain (less than 2 percent slope), or buried below liquefaction depth successfully avoided harmful effects of subsidence or spreading.

2. Avoidance of unstable slopes in the vicinity of the Denali Fault proved to be an effective slope stability design strategy. Actual earthquake ground motions (0.34g), however, were less than ground motions used to assess potential geohazards (0.60g).

3. As has been observed worldwide for buried steel pipelines with good quality welds, seismic wave propagation did not damage or permanently deform the below-ground pipeline. Estimated maximum pipe strain was less than the specified minimum yield strength of the pipeline.

4. Post-event inspection of the pipeline using the instrumented curvature/deformation monitoring pig was an effective and conclusive technique for verifying pipeline integrity. The pig data provided a continuous record of pipe displacement and curvature through the area affected by the earthquake.

5. The usual design approach for pipeline fault crossings is to construct the pipeline in shallow, sloped-wall trench with loose backfill while permitting large strains and permanent deformation to occur, provided pipe rupture is prevented. In other words, the risk of damage to the pipe requiring repair is generally acceptable, so long as leakage is prevented. Had this concept been used on TAPS, an extensive pipe repair operation would have been required. However, since the pipeline crosses the Denali Fault above grade on sliding shoe supports, the pipeline was not subjected to the large bending strains and local buckling that would have resulted in a shallow buried pipeline. While

fault rupture is a rare event, it certainly happened in the case of TAPS, and as planned, the above-ground crossing mode prevented damage that would have resulted in a more significant interruption in throughput.

Acknowledgment

Alyeska Pipeline Service Company is gratefully acknowledged for its role in supporting field reconnaissance of the TAPS route following the Denali Fault earthquake and for permission to present this paper. Any opinions expressed herein are solely those of the authors.

1.0 INTRODUCTION

At the request of HDR and the EIS agencies during workshops on July 12, 2010, and in order to expedite further development of potential alternatives to ExxonMobil's (Applicant) proposed Point Thomson Project that would be analyzed in the EIS, ExxonMobil has prepared conceptual project scenarios for three alternatives (3A, 3B and 4). These alternatives were independently formulated by the EIS agencies and HDR without ExxonMobil involvement.

These project scenarios describe the major engineering and construction activities and related schedules for each scenario. Preliminary risks, challenges and issues associated with the alternatives are also identified. These responses supplement ExxonMobil's June 25, 2010 comments to the EIS agencies and HDR with respect to practicability and purpose and need of the proposed alternatives (ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components).

Although plans for the alternatives have not been engineered, ExxonMobil has applied the experience and knowledge gained from the three years of engineering and planning expended for the proposed Point Thomson Project (EIS Proposed Action), as well as the current drilling program, to develop scenarios that are reasonable and suitable for environmental impact analysis. This effort relied upon experienced Point Thomson personnel who have used their best professional judgment over the short time frame available to respond.

These scenarios must be distinguished from the extensive, multi-year process of planning and engineering for actual execution of a proposed Project. Because the proposed alternatives are conceptual in nature based on general versus specific goals to mitigate potential impacts (for example, to coastal resources or wetlands), ExxonMobil's scenarios are also conceptual. The potential alternatives at this stage, with some exceptions, lack specificity such as precise locations, sizes, or preferred technical approaches. Likewise in the scenarios all dates, material quantities and the like are very general estimates. ExxonMobil recognizes that the draft alternatives are also subject to refinement through revisions to base case assumptions, substitution of potential components and further

screening. Moreover, while these scenarios have not been engineered, ExxonMobil believes that they provide a sound experiential and practical foundation, sufficient for EIS evaluation.

In this response, ExxonMobil generally has not commented on or identified environmental impacts arising from the alternatives that may be different from the Proposed Action. Similarly, ExxonMobil has not commented on costs or determined the commercial viability of the alternative. It should not be assumed that this alternative which has not been engineered is commercially viable, nor should this response be understood as ExxonMobil's agreement with the alternative or its components and assumptions. The information provided in these scenarios is intended to assist in impact analysis by the EIS agencies and HDR. ExxonMobil may comment on environmental impacts or costs of the alternatives at appropriate opportunities in the EIS process.

1.1 Comments on Execution Schedules

In the Alternate 3A scenario descriptions below, ExxonMobil has estimated the time required to conduct engineering on the alternative, including gathering necessary field information, and to obtain permits would delay the commencement of construction by about two years when compared to Alternative 2, e.g., commencement of construction for Alternative 3A would be delayed until 4Q 2013 vs. 4Q 2011 for Alternative 2. Alternative 3A as noted in ExxonMobil's June 25, 2010 response, does not meet the Project's purpose and need with respect to ExxonMobil's commitment to the State of Alaska for production in 2014.

2.0 DESCRIPTION OF ALTERNATIVE 3A

This section summarizes ExxonMobil's understanding of the principal features of the base case for Alternative 3A. These assumptions have been clarified and confirmed by HDR as a step in the development of the conceptual scenarios. This alternative contains numerous sub-options or components which, for purposes of this response, are not considered as part of the base case and therefore not addressed in this document. (These other options or components have been or may be addressed separately as may be appropriate.) Also, in order to focus the input of the appropriate engineering and execution teams, the principal

features of this Alternative have been further categorized into the major project scopes of Infrastructure, Pipeline, Drilling and Facilities.

2.1 Infrastructure

The main Infrastructure features of Alternative 3A are outlined below and also shown in Figures 1 and 2.

- Gravel Roads:
  - 44 mile all season gravel road (32' crown x 5' deep min.) from the Endicott Road to Point Thomson. Because of the length of time required to conduct engineering and additional environmental studies, acquire permits, and construct the road, it is assumed that it will be available for the long term operation of Point Thomson but not during the Point Thomson Project construction phase.
  - All major components of the Project (i.e. pads, airstrip, gravel mine) connected by in-field gravel roads (32' crown x 5' deep min.) as shown in Figure 1.
- Tundra Ice Roads:
  - Because the gravel road from Endicott to Point Thomson will not be available until after Project startup and neither barging nor a sea ice road will be allowed, construction of the Project's facilities are assumed to be supported by a seasonal 44 mile onshore or tundra ice road between the Prudhoe Bay area and Point Thomson that is adequate to transport sealift modules up to 1300 tons (does not include transport apparatus which weighs approximately 300 tons) across three major river crossings. A tundra ice road would also be used to support operations. This tundra ice road would be rebuilt each year for 3 years.
- Gravel Pads:
  - Central Pad split into two pads – a Central Well Pad on the existing Central Pad drilling location and a second pad located 2 miles inland containing process facilities, camp, warehouse, Class I disposal well, etc. (Central Processing Facility Pad)
  - East and West Well Pads relocated approximately 1/2 mile inland. (Not shown in Fig. 1). For ExxonMobil's discussion of well pad locations, refer to Practicability of Point Thomson Draft Alternatives, ExxonMobil Technical Brief #1- Well Pad

Locations (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010).

- Airstrip:
  - Gravel airstrip located at the site of the former West Staines State #2 airstrip
  - Airstrip design and footprint unchanged from ExxonMobil's proposal (5600'x 200')
- Barge Offload Facility/Barging
  - No module offloading at Point Thomson. Modules to be offloaded at West Dock in Prudhoe Bay and transported via tundra ice road to Point Thomson
  - No coastal barging support
- Gravel mine / Water source –
  - Point Thomson area gravel mine/water source co-located with facilities and living quarters pad
  - Gravel mines located approximately every five miles along the Endicott-Point Thomson road

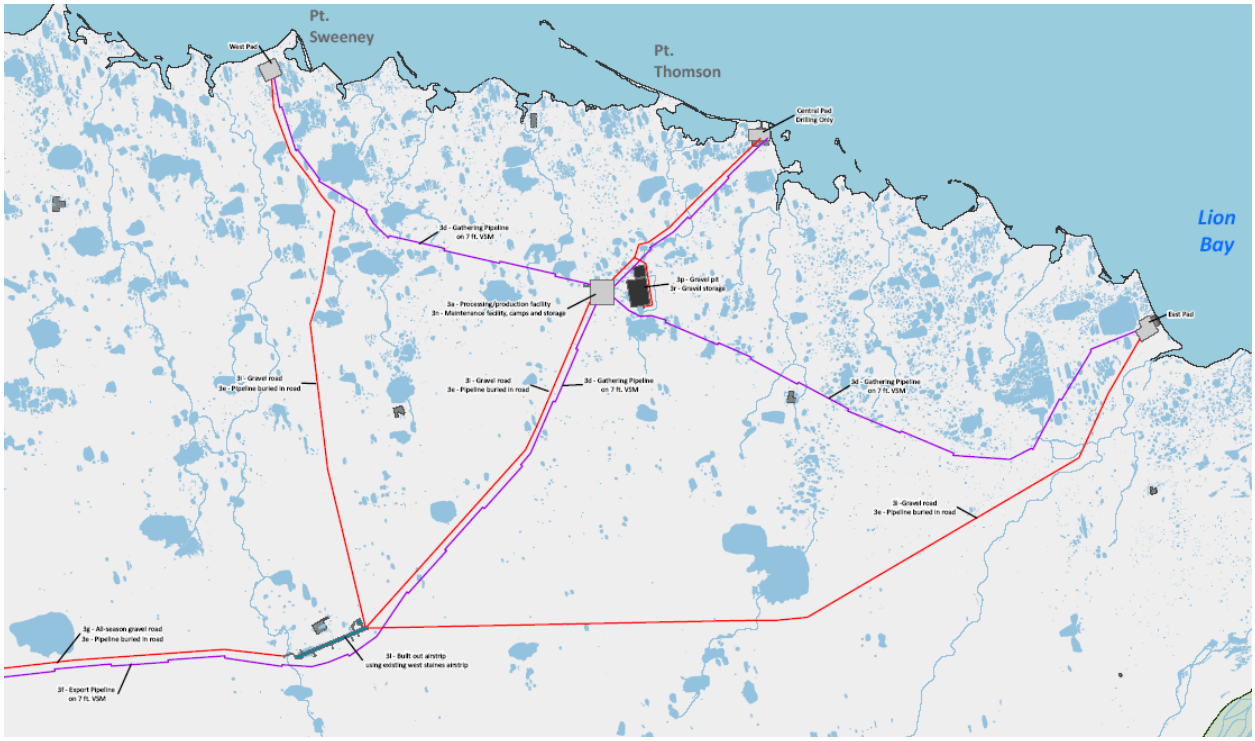

Figure 1 – Alternative 3A Site Layout – Main Features (provided by HDR)

2.2 Pipeline

The main Pipeline features of Alternative 3A are outlined below and also shown in Figures 1 and 2.

- Export Pipeline (refer to Figure 2):
  - Approximately 50 mile of 12" export pipeline constructed on Vertical Support Members (VSMs) 7-feet above the tundra from Central Processing Facility (CPF) to tie in to Endicott oil sales pipeline. The export pipeline will have a minimum of 500' distance from the all season gravel road
  - Pig launcher and custody transfer meter facility at CPF
  - Pig receiver and surveillance meter facility at Endicott junction
  - Approximately 50 miles of fiber optic cable from CPF to Endicott junction
  - Control module and generator at Endicott junction.
- In-field pipelines
  - Gathering (production) lines consisting of 8" heat traced pipelines installed on VSMs 7-feet above the tundra as follows (refer to Figure 1)
    - Approximately 4 miles from the West Well Pad
    - Approximately 6 miles from the East Well Pad
    - Approximately 2 miles from the Central Well Pad
  - Pig launcher and receiver facilities at West, Central, and East Well pads for gathering lines and production line
  - Approximately 4 miles of fiber optic cable and power cable from CPF to West Well Pad
  - Approximately 6 miles of fiber optic cable and power cable from CPF to East Well Pad
  - Approximately 2 miles of fiber optic cable and power cable from CPF to Central Well Pad

- Gas re-injection line (refer to Figure 1):
  - Approximately 2 miles of 10” gas re-injection line, constructed on shared VSM 7 feet above the tundra from CPF to Central Well Pad
  - Pig launcher and receiver facility at CPF and Central Well Pad (shared modules with production line)

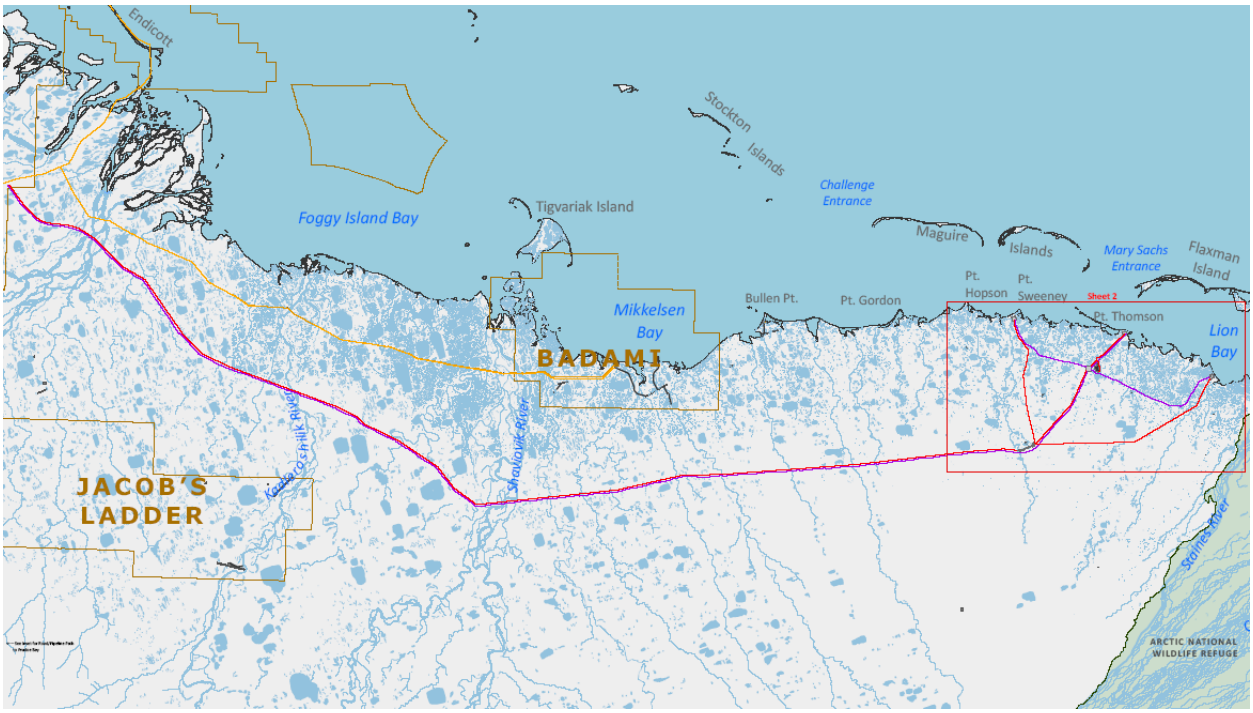

Figure 2 – Alternative 3A – Point Thomson Connection to Existing Infrastructure in Prudhoe Bay (provided by HDR)

2.3 Facilities

The main Facilities features of Alternative 3A are outlined below.

- Compression Technology
  - Production processing using reciprocating compression technology.
  - ExxonMobil understands the preliminary 3A Alternative assumed the use of centrifugal compression technology. As described in Practicability of Point Thomson Draft EIS Alternatives, ExxonMobil Technical Brief #2 – Centrifugal Compressors (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010) (to be supplemented pursuant to the workshop held on July 29, 2010), ExxonMobil does not believe it would be

practicable to use centrifugal compression technology for the Point Thomson Project.

- Module Size
  - Module weights limited to historic proven technology for ice road transportation and not to exceed 1300 tons
- Wells
  - Five production/injection wells and one disposal well located as follows
    - One production and one injection well on the Central Well Pad
    - One production well on the East Well Pad
    - One production well on the West Well Pad
    - One additional production well on one of the three well pads
    - One disposal well on the Central Processing Facility Pad

3.0 TIMELINE

3.1 Infrastructure Construction

The processing facilities and pipelines in Alternative 3A would be installed in three separate construction seasons. The first season (2013-14) will include ice road installation from Deadhorse to Point Thomson; construction camp installation; mine site development; gravel placement for the Central Processing Facility Pad, airstrip, and the connecting roads; culverts and bridge installation; and infrastructure piling and foundations. The second season (2014-15) will include ice road installation from Deadhorse to Point Thomson; gravel for the East and West Well Pads and access roads; culverts and bridge installation; infrastructure piling; mine site closeout and rehabilitation; and buildings and module piling. The third season (2015-16) will include ice road installation from Deadhorse to Point Thomson for the movement of the processing modules and module installation and hookup.

3.2 Endicott to Point Thomson Road Construction

A 44 mile gravel road connecting the Point Thomson area with the Endicott Spur Road is to be constructed. As shown on Table 1, it will take more time to conduct engineering and field studies and to obtain site specific permits for the road than for installation of the base

Point Thomson Project infrastructure, pipelines, and facilities. Consequently, it is assumed the gravel road will provide support for long term operations and later drilling but not for the installation of the base Project facilities and infrastructure.

3.3 Pipeline Construction

Alternative 3A would be executed in three separate construction seasons. The first season (2013-14) will include ice roads, VSMs and crossings* of the major rivers for the export pipeline. The second season (2014-15) will have another ice road (work pad) to lay and weld the export pipeline, install fiber optic and power cables, hydrostatically test the pipeline in the Summer, install launcher/receiver/meter facilities, and pre-commission the Export Pipeline. The third year (2015-16) will include ice roads, VSMs, lay and weld the infield gathering and gas reinjection lines, install infield power lines and fiber optic cables, install launcher/receiver facilities, hydrostatically test and pre-commission the gathering and gas re-injection lines.

Construction crews for the export pipeline will be housed primarily in Deadhorse and at Point Thomson with a supplemental remote camp on an ice pad in the vicinity of the half way point of the pipeline. Construction crews for the gathering lines will be housed in Point Thomson.

As with the applicant's proposed case and the other alternatives the VSMs will be pre-fabricated off slope and delivered to the construction ice road by truck. The pipe sections will be double jointed (two joints welded together), Fusion Bond Epoxy coated and insulated in Fairbanks, loaded and delivered to the North Slope by the pipeline installation contractor or his sub contractor.

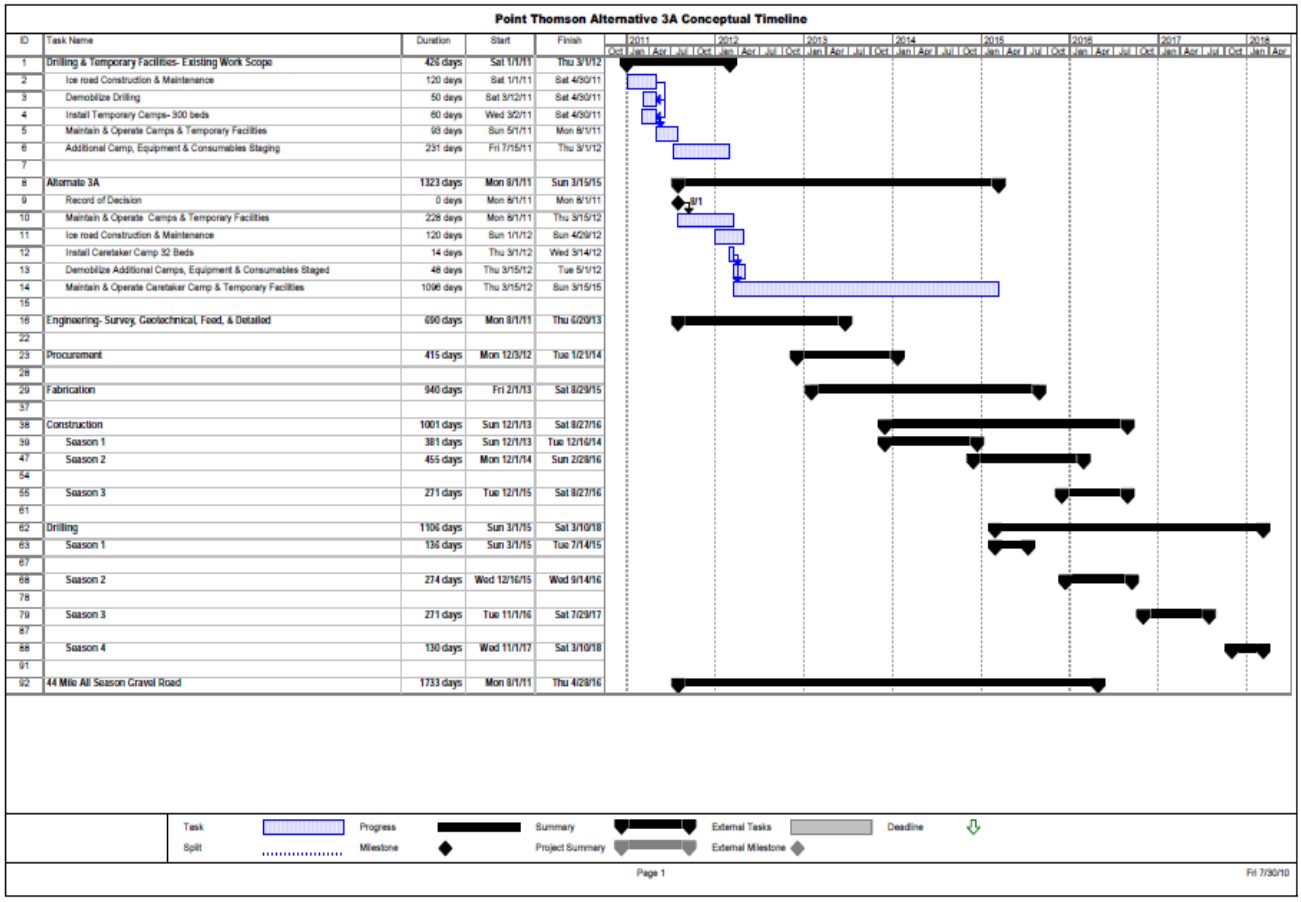
* The export pipeline river crossings will be separate from the nearby major bridges for the all season gravel road. Ordinarily, the pipeline would be suspended on these road bridges. Since the road bridges will not be ready for several more seasons, the pipeline will be installed in its own dedicated river crossing bridges.

3.4 Facilities Construction

The Facility modules will be fabricated off the North Slope and sea lifted to Prudhoe Bay via ocean going barges during the 2015 summer season. The modules will be offloaded at Prudhoe Bay West Dock and temporarily stored in the Deadhorse area. A tundra ice road will be built from Endicott to Point Thomson during the 2015-16 winter season allowing the modules to be transported to the Point Thomson Site in 1-2Q 2016.

Construction crews will be housed primarily at Point Thomson to allow for infrastructure foundations, hook-up and commissioning activities to commence when the modules arrive for an expected facility startup by year end 2016.

3.5 Drilling



The well work for Alternative 3A would take place over four years, with the drilling rig being demobilized over the all season gravel road during the fourth season. The drilling rig would be mobilized during the spring of 2015 over ice roads, along with all of the supplies and materials needed to drill the disposal well. Equipment associated with the Grind and Inject facility and well cuttings would also be mobilized at this time. The disposal well would be drilled and completed by late spring. The Grind and Inject facility would be installed that summer.

During the 2015-16 ice road season, the drilling rig would be moved North to the Central Well Pad and resupplied. The PTU #15 and 16 wells would be completed. This would carry into the summer. By this time (mid 2016) the all season gravel road would be available and the drilling program could be supported year-round. Drilling would continue on the remaining three wells, utilizing as much of the year as possible by performing drilling above the hydrocarbon threshold in the summer months and drilling below the hydrocarbon threshold in the winter. This would allow all three remaining wells to be completed in less than two years which would complete the drilling program by March 2018.

Table 1 – Conceptual Scenario - Level 1 Timeline for Alternative 3A

Point Thomson Alternative 3A Conceptual Timeline

ID	Task Name	Duration	Start	Finish
1	Drilling & Temporary Facilities- Existing Work Scope	426 days	Sat 1/1/11	Thu 3/1/12

4.0 SUMMARY OF CIVIL WORKS AND PIPELINES

4.1 Infrastructure

ALTERNATIVE 3A ESTIMATED CIVIL WORKS		
Access Road (50 miles x 32')	**Item**	**Estimated Quantity**
	Gravel Road	360 Acres/3,200,000 CY
	Bridges < 100'	11
	100'<Bridges < 500'	3
	1000'<Bridges < 2000'	1
	2000'<Bridges < 4000'	2
	Culvert	400-600
	Ice Road	60,000,000 Gallons/yr

Infield Roads (21 miles x 32')	**Item**	**Quantity**
	Gravel Road	152 Acres/1,550,000 CY
	Culvert	200-300

Ice Road Access to Point Thomson	**Item**	**Quantity**
	Season 1	75,000,000 Gallons
	Season 2	75,000,000 Gallons
	Season 3	75,000,000 Gallons

Gravel Mines	**Item**	**Quantity**
	Gravel Mine #1 (Access Road)	365,000 CY
	Gravel Mine #2 (Access Road)	365,000 CY
	Gravel Mine #3 (Access Road)	365,000 CY
	Gravel Mine #4 (Access Road)	365,000 CY
	Gravel Mine #5 (Access Road)	365,000 CY
	Gravel Mine #6 (Access Road)	365,000 CY
	Gravel Mine #7 (Access Road)	365,000 CY
	Gravel Mine #8 (Access Road)	365,000 CY
	Gravel Mine #9 (Access Road)	365,000 CY
	Gravel Mine #10 (Infield Roads-Pads)	3,300,000 CY

Gravel Pads	**Item**	**Quantity**
	East Well Pad	18 Acres/208,000 CY
	West Well Pad	18 Acres/280,000 CY
	Central Well Pad	15 Acres/230,000 CY
	Facilities Pads	35 Acres/500,000 CY

Airstrip	**Item**	**Quantity**
	Gravel Airstrip	475,000 CY

Emergency Response Boat Launch	**Item**	**Quantity**
	Ramp	0.1 Acre/84 CY
	Piles	6 each/ <0.1 Acre

4.2 Pipeline

	Item	Descriptions
Export Pipeline Condensate (from CPF to Endicott Junction)	Design Code	ASME B. 31.4 and 49 CFR Part 195
	Length	Approx 50 miles
	Outside Diameter	12.75 inch
	Design Flowrate	70,000 bpd
	Design Pressure	2035 psig
	Material	Carbon Steel

	Item	Descriptions
East and West Gathering Line (from East/West Pad to CPF)	Design Code	ASME B. 31.8
	Length	East approx 6 miles, West approx 4 miles
	Outside Diameter	8.625 inches
	Design Flowrate	200 Mscfd
	Design Pressure	8800 psig
	Material	Duplex 2205

	Item	Descriptions
Production Gathering Line (from Central Pad Drilling to CPF)	Design Code	ASME B. 31.8
	Length	approx 2 miles
	Outside Diameter	8.625 inches
	Design Flowrate	200 Mscfd
	Design Pressure	8800 psig
	Material	Duplex 2205

	Item	Descriptions
Gas Re-injection line (from CPF to Central Pad Drilling)	Design Code	ASME B. 31.8
	Length	approx 2 miles
	Outside Diameter	10.75 inches
	Design Flowrate	200 Mscfd
	Design Pressure	12,000 psig
	Material	Carbon Steel

5.0 IMPACTS

5.1 Facility

Alternative 3A requires utilizing the existing Prudhoe Bay West Dock in-field gravel roads to Deadhorse, and existing gravel storage pads. It may require expansions of the gravel roads (widening) and gravel pads. Tundra ice roads are built for transporting facility modules from Deadhorse to Point Thomson. Based on previous projects the maximum module weight transported on an ice road was approximately 1300 tons. Initial screening was conducted for this conceptual scenario to revise the number of modules needed to provide the identical process capability based on the historic maximum module weight and resulted in an increase in the number of facility modules from the base case by a factor of three to four.

An additional six months for re-engineering would be required to make the necessary changes to the FEED (Front End Engineering Design) effort based on the alternative's module weight constraints. Additional detailed engineering would be required before procurement and module fabrication could begin leading to a minimum one-year delay in module shipment (summer 2015 vs. 2014). This delay combined with the need to stage the modules in Deadhorse for ice road delivery in the winter of 2015-16 would lead to a minimum two year delay in start-up. Refer to Table 1 – Conceptual Scenario - Level 1 Timeline for Alternative 3A. The delay would result in the project site requiring care-taker activities and maintenance of temporary facilities for the first two years to accommodate construction startup from 2012 to 2014. These first two years will have an impact on logistics both air and land, as well as associated power generation, solid and liquid waste generation and handling, vehicular traffic, road and pad maintenance. Ice roads may have to be built each year to maintain safe access and for resupply.

The installation man-hours (on the North Slope) for the process facilities are estimated to be more than double the base case because there are more components that must be interconnected in the field. Similarly, it is estimated that 50% more man-hours would be needed to achieve functional check-out and systems completion because there are more components that must be interconnected in the field.

The overall tundra take would likely increase if drilling rig space is required at both the Central Well Pad and the Facilities Pad for the disposal well. The larger number of process modules with the minimum required safe space between and around them will require a larger area. Further study is required to assure sufficient lay-down space for construction, drilling and operations. The number of support piles under the modules and pre-assembled units are expected to more than triple from the base case.

5.2 Pipeline

This alternative requires building of additional 28 miles of 12” export pipeline and fiber optic cable that parallels the underutilized 12” Badami Sales Oil Pipeline. This duplication of common carrier export pipelines increases environmental impact both during construction and operations.

The 35 to 50 feet wide pipeline ice right of way will be built several hundred feet away from the tundra ice road to Point Thomson to have a safety stand-off between equipment and materials being hauled down the tundra ice road and the personnel constructing the pipeline. Larger construction crews, extended schedules with the associated construction equipment, and construction camp are required since the export pipeline length has been doubled for this alternative.

Moving the Central Processing Facility 2 miles south of the Central Well Pad also results in two additional in-field pipelines (8” gathering line and 10” gas re-injection line). These two additional pipelines increase the possible total spill volume, and require additional manpower, equipment, and camp space to construct. These two pipelines also result in an addition of pipeline facilities such as pig launchers and pig receivers for each line, fiber optic cable, and power cable between Central Processing Facility and Central Well Pad.

5.3 Wells

Without barging support, initially all major equipment and material mobilization and resupply must occur during the ice road season or by air once the air strip is in place. In order to have the disposal well available for first production and have both producing wells available for first production, a drilling rig would be mobilized during the spring of 2015 over

ice roads, along with all of the supplies and materials needed to drill the disposal well. The equipment associated with the Grind and Inject facility would also be mobilized at this time. The disposal well would be drilled and completed immediately after drilling rig mobilization. The disposal well would not be completed until after the loss of ice roads to Deadhorse for resupply, so the drilling rig would remain at the Central Processing Facility Pad until late Fall of 2015. At that time it would be moved over infield roads to the Central Well Pad, resupplied and the PTU 15 and 16 wells would be completed. This would be timed in such a way that the first completion could be supplied by rolligon, prior to completion of ice roads. The second completion would then be resupplied by ice road and would continue into the summer months.

In the spring of 2016, the all season gravel road would become available and the drilling operation could then be supported year-round. The drilling rig (rig) would move to the East Well Pad and drill Well #3's surface hole. The rig would then move to the West Well Pad and drill Well #4's surface hole by mid-September, 2016. The rig would then be on standby until the beginning of the winter drilling season, November 1, 2016. Well #4 would be drilled to total depth and cased by early January 2017. The rig would then move back to the East Well Pad and drill Well #3 to total depth and case it, taking advantage of the available drilling season prior to April 15, 2017. This well would then be cased and completed by late April 2017. The rig could then be moved back to the West Well Pad and Well #4 could be completed, carrying into the summer of 2017.

Upon completing Well #4, the rig would move to the fifth well and drill the surface hole. It would then standby until November 1, 2017, when it could continue to drill Well #5 to total depth, case and complete it. This should be done by early February 2018 and the rig could be demobilized.

5.4 Logistics

An all season gravel road, once built, from Endicott to Point Thomson will enhance the long term efficient logistical support of the site and facilities for ongoing operations of the Point Thomson Project facilities as well as supporting reasonably foreseeable future development activities.

The all season gravel road will not be completed in time to support the construction of the facilities, infrastructure, export pipeline or disposal well drilling.

All Season Gravel road Benefits:

- Will support year round normal transport of support materials and equipment, spares, personnel, food, fuel, and normal truckable equipment from Deadhorse to Point Thomson for drilling and ongoing operations support after construction.
- Reduced need for storage facilities at the sites due to all season availability of supplies and materials. Some staging and storage of required materials and equipment can be moved back to existing facilities at Deadhorse, Anchorage and Fairbanks via road transport.
- Provide an overland means for monitoring the export pipeline route and improving incident response route.

Alternative 3A Negatives

- The limitation of no summer barging or resupply to support current schedule and plans for construction of the facilities and infrastructure will require reliance on Winter ice roads only and continued transport of personnel by helicopter / aircraft until the gravel airstrip is in place during non-ice road months.
- Large staging and storage areas will need to be acquired or constructed to enable the marshalling of materials and equipment ready to take advantage of the ice road season.
- The volume of trucks will be difficult to obtain with existing available transport companies in Alaska that have suitable equipment for ice road transport.
- Urgent resupply and materials transport will require additional helicopter support and flights between Deadhorse and Point Thomson when ice roads are not available. The helicopters will be offset by fixed wing aircraft for material and small equipment flights after the completion of the permanent gravel air strip.
- Drilling support, pipelines and construction will require use of an inland ice road to Point Thomson to support construction prior to a permanent all season gravel road.
- The requirement to use only seasonal ice roads for transport for the construction will greatly limit the volume of materials and equipment shipments by the severe limitation of open shipping windows within the usable ice road seasons.

- This will likely require a longer construction and drilling schedule for additional years to complete the proposed work.

Module Transport:

- Transport from Prudhoe Bay to Point Thomson will require more numerous and smaller modules. There will be a need to design and utilize multi-wheel transport trailers and vehicles able to spread the load and wheel bearing on the ice road for transport. The number of modules, interconnecting materials, piles, etc will increase ice road trucking trips and increase exposure to wildlife encounters.
- The smaller size modules will require the transport and housing of larger work forces, larger camps, more resupply and possibly a longer construction schedule extending the length of time to complete the construction and startup.

6.0 ISSUES

This is a very preliminary screening study for purposes of EIS alternative comparison and is based upon the best professional judgment of the individuals involved and collective knowledge and experience as detailed in the Section 1.0. Due to the limited definition of the alternative and limited time available for evaluation, there are a number of critical issues which were not and could not be fully addressed. This section is intended to identify the more significant issues that would need further evaluation before the alternative could be capable of being implemented in the estimated timeframe.

6.1 Infrastructure

Geotechnical Investigation:

- Requires a geotechnical investigation for the road route, all bridges, and mine sites reconnaissance and development.

Hydraulics/Hydrology Study:

- Requires a hydraulics and hydrology study for all bridges, culverts and roadway. As part of this study, breakup and ice characteristics should be determined.

Survey:

- Requires route survey as well as detailed topography at bridge crossings for final alignment.

Water Balance Study:

- Construction water requirements need to be established and sources need to be identified and permitted, particularly with respect to ice roads and pads. It is expected that fresh water resources will be taxed due to demand on the part of other consumers (projects) along the route.
- Camp water source at C-1 Pit is no longer available by access road for the first two construction seasons, requiring a pipeline and pump house to be installed for water access.

Access Bridge Performance Requirements:

- A determination of the vehicle usage and capacity for all bridges needs to be developed. This should weigh the cost versus benefit of designing all bridges for rig crossings or utilizing ice roads/bridges at all or certain key locations.

Permitting:

- Previous direction has been to span the non-vegetated portion of stream crossings. From a hydrological standpoint, this is not necessary. Permitting requirements need to be fully understood by all parties.

Security Issues:

- Security concerns related to tie-in with other providers in the Prudhoe area will need examination.

Tundra Ice Road:

- This alternative does not permit sealift barging of modules; instead it assumes a tundra ice road will be utilized for all movement of modules. Topographic surveys of the route would need to be conducted to confirm feasibility of transporting modules on the tundra ice road. Should a tundra ice road be determined to be infeasible for any reason (such as angle of incline, water availability, or ungrounded river crossings), a coastal sea ice road would need to be utilized

instead under this option. A tundra ice road would still be used for operations re-supply purposes, if feasible.

Centrifugal Compressors

- Refer to Practicability of Point Thomson Draft EIS Alternatives, ExxonMobil Technical Brief #2 – Centrifugal Compressors (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010).

6.2 Pipeline

Field Data Gathering:

- This alternative is located further South of the original export pipeline and gathering lines route, therefore additional centerline survey, hydrology data, and geotechnical data gathering will be required to complete detail engineering design. Geotechnical data gathering for bridges, rivers, and road crossing needs to be performed in Winter 2011, while the river spring breakup data and centerline survey need to be performed by the Summer of 2012 to ensure the pipeline detail engineering can be completed by January, 2013. Any slippage to the field data gathering schedule will impact the overall pipeline construction completion.

Gathering Lines issues:

- This alternative also separated the Central Well Pad from the Central Processing Facility, therefore operational issues related to 2 miles of production lines and gas re-injection lines will have to be identified and addressed such as having to manage events arising from plant shutdowns with resulting product cooling and potential formation of hydrates blocking the line. The additional pipeline length will amplify operational issues considerably.

6.3 Facilities

Module Size:

- Alternative 3A changes the module size envelope and as such the modularization criteria will have to be reexamined. The smaller and lighter modules will create issues pertaining to the level of details of the interconnections between the various

modules. Significant inefficiencies will also be created due to the splitting of modules with shared equipment such as the compressors that have shared process equipment and the generators with the shared waste heat recovery unit. Increasing the maximum module weight beyond the previously proven 1300 tons would require feasibility studies to examine ice road capacities as well as ice road detours and crossings of rivers/streams. Results will have to be incorporated in the design.

Processing Facility Pad Location:

- Moving the Central Processing Facility Pad further south increases the distance between the wellheads and the facility. Further studies need to be conducted to address the implications on the facility design and pipeline route due to the addition of 2 miles of very high pressure heavy wall gas injection line.

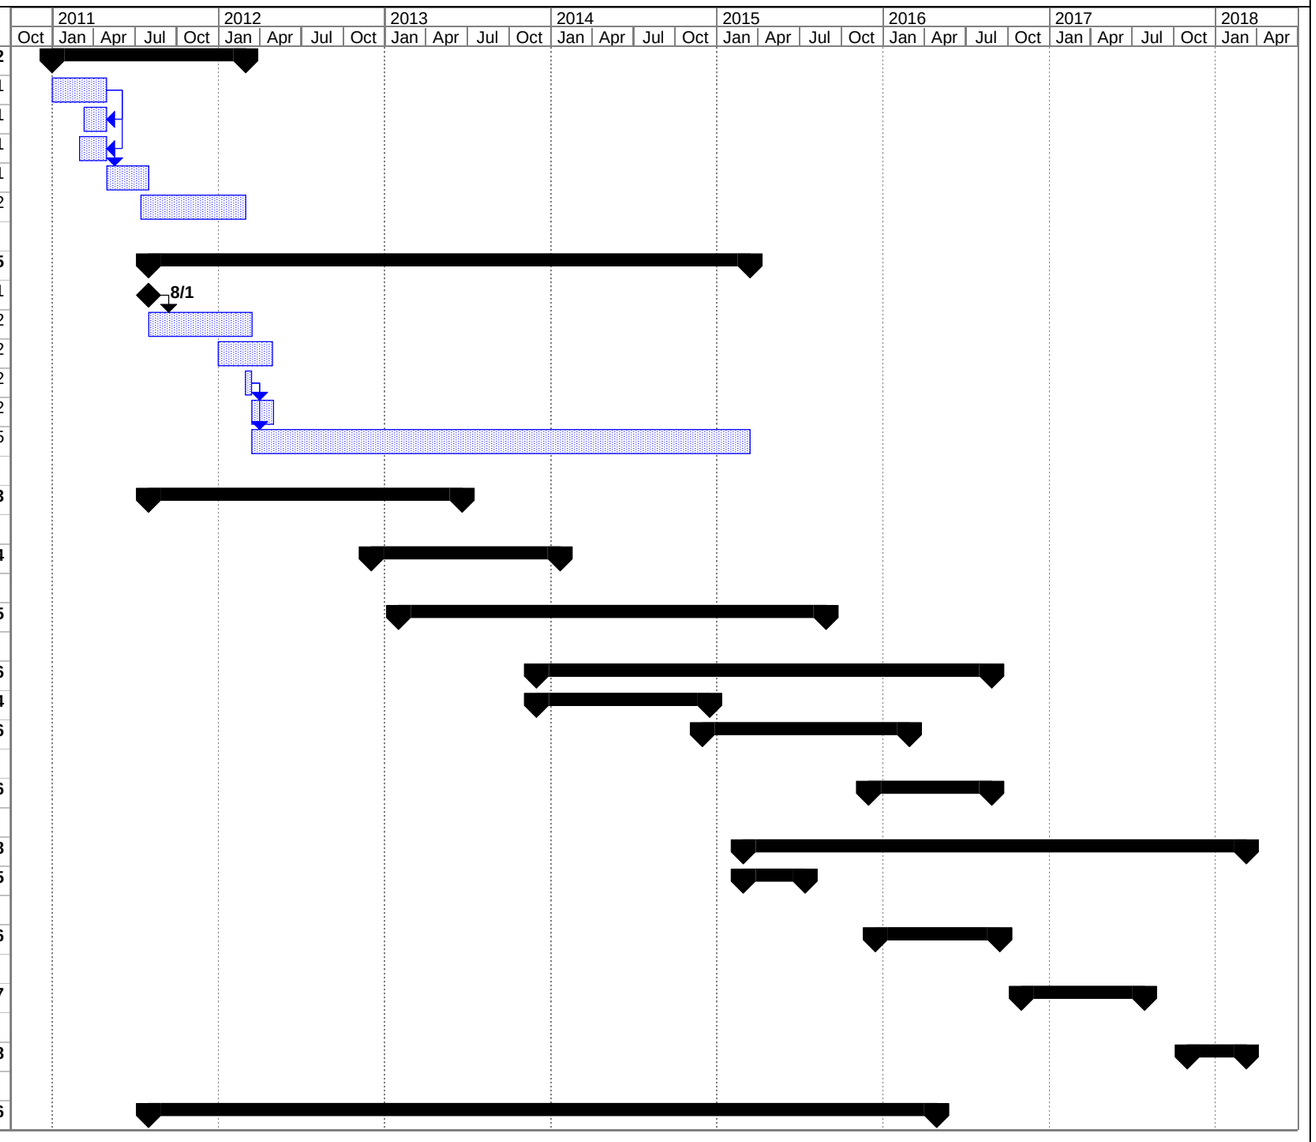
Well Pad Locations:

- Refer to Practicability of Point Thomson Draft Alternatives, ExxonMobil Technical Brief #1- Well Pad Locations (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010).

6.4 Wells

Drilling Program:

- The primary impact of the Alternative 3A on the drilling program is that of extending the schedule due to the loss of barging support the first season. This restricts resupply activities to the ice road season, extending the schedule about one year relative to the base case development plan.



6.5 Logistics

Larger workforce and supporting infrastructure:

- The smaller size modules will require more onsite hook-up and commissioning work at Point Thomson. This will require the transport and housing of larger work forces, larger camps, more resupply and possibly a longer construction schedule extending the length of time to complete the construction and startup.

Point Thomson Alternative 3A Conceptual Timeline

1.0 INTRODUCTION

At the request of HDR and the EIS agencies during workshops on July 12, 2010, and in order to expedite further development of potential alternatives to ExxonMobil's (Applicant) proposed Point Thomson Project that would be analyzed in the EIS, ExxonMobil has prepared conceptual project scenarios for three alternatives (3A, 3B and 4). These alternatives were independently formulated by the EIS agencies and HDR without ExxonMobil involvement.

These project scenarios describe the major engineering and construction activities and related schedules for each scenario. Preliminary risks, challenges and issues associated with the alternatives are also identified. These responses supplement ExxonMobil's June 25, 2010 comments to the EIS agencies and HDR with respect to practicability and purpose and need of the proposed alternatives (ExxonMobil Preliminary Response to Point Thompson EIS Draft Alternatives and Components).

Although plans for the alternatives have not been engineered, ExxonMobil has applied the experience and knowledge gained from the three years of engineering and planning expended for the proposed Point Thomson Project (EIS Proposed Action), as well as the current drilling program, to develop scenarios that are reasonable and suitable for environmental impact analysis. This effort relied upon experienced Point Thomson personnel who have used their best professional judgment over the short time frame available to respond.

These scenarios must be distinguished from the extensive, multi-year process of planning and engineering for actual execution of a proposed Project. Because the proposed alternatives are conceptual in nature based on general versus specific goals to mitigate potential impacts (for example, to coastal resources or wetlands), ExxonMobil's scenarios are also conceptual. The potential alternatives at this stage, with some exceptions, lack specificity such as precise locations, sizes, or preferred technical approaches. Likewise in the scenarios all dates, material quantities and the like are very general estimates. ExxonMobil recognizes that the draft alternatives are also subject to refinement through revisions to base case assumptions, substitution of potential components and further

screening. Moreover, while these scenarios have not been engineered, ExxonMobil believes that they provide a sound experiential and practical foundation, sufficient for EIS evaluation.

In this response, ExxonMobil generally has not commented on or identified environmental impacts arising from the alternatives that may be different from the Proposed Action. Similarly, ExxonMobil has not commented on costs or determined the commercial viability of the alternative. It should not be assumed that this alternative which has not been engineered is commercially viable, nor should this response be understood as ExxonMobil's agreement with the alternative or its components and assumptions. The information provided in these scenarios is intended to assist in impact analysis by the EIS agencies and HDR. ExxonMobil may comment on environmental impacts or costs of the alternatives at appropriate opportunities in the EIS process.

1.1 Comments on Execution Schedules

In the Alternate 3B scenario descriptions below, ExxonMobil has estimated the time required to conduct engineering on the alternative, including gathering necessary field information and to obtain permits, would delay the commencement of construction by about two years when compared to Alternative 2, e.g., commencement of construction for Alternative 3B would be delayed until 4Q 2013 vs. 4Q 2011 for Alternative 2. Alternative 3B as noted in ExxonMobil's June 25, 2010 response, does not meet the Project's purpose and need with respect to ExxonMobil's commitment to the State of Alaska for production in 2014.

2.0 DESCRIPTION OF ALTERNATIVE 3B

This section summarizes ExxonMobil's understanding of the principal features of the base case for Alternative 3B. These assumptions have been clarified and confirmed by HDR as a step in the development of the conceptual scenarios. This alternative contains numerous sub-options or components which, for purpose of this response, are not considered as part of the base case and therefore not addressed in this document. (These other options or components have been or may be addressed separately as may be appropriate). Also, in order to focus the input of the appropriate engineering and execution teams, the principal

features of this Alternative have been further categorized into the major project scopes of Infrastructure, Pipeline, Drilling and Facilities.

2.1 Infrastructure

The main Infrastructure features of Alternative 3B are outlined below and also shown in Figures 1 and 2.

- Gravel Roads:
  - All major components of the Project (i.e. pads, airstrip, gravel mine) connected by in-field gravel roads (32' crown x 5' deep min.) as shown in Figure 1.
- Tundra Ice Roads:
  - Onshore or tundra ice road between the Prudhoe Bay area and Point Thomson that is adequate to transport sealift modules up to 1300 tons (does not include transport apparatus which weighs approximately 300 tons) across three major river crossings. This tundra ice road would be rebuilt each year thereafter, in order to complete the Project and subsequently for Drilling and Operations.
- Gravel Pads:
  - Central Pad split into two pads – a Central Well Pad on the existing Central Pad drilling location and a second pad located 2 miles inland containing process facilities, camp, warehouse, Class I disposal well, etc. (Central Processing Facility Pad)
  - East and West Well Pads relocated approximately 1/2 mile inland. (Not shown in Fig. 1). For ExxonMobil's discussion of well pad locations please refer to Practicability of Point Thomson Draft Alternatives, ExxonMobil Technical Brief #1-Well Pad Locations (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010).
- Airstrip:
  - Gravel airstrip located 1 mile northeast of the former West Staines State #2 airstrip
  - Airstrip design and footprint unchanged from ExxonMobil's proposal (5600'x 200')
- Barge Offload Facility/Barging
  - No module offloading at Point Thomson. Modules to be offloaded at West Dock in Prudhoe Bay and transported via tundra ice road to Point Thomson
  - No coastal barging support

- Gravel mine / Water source –
  - Point Thomson area gravel mine/water source co-located with facilities and living quarters pad

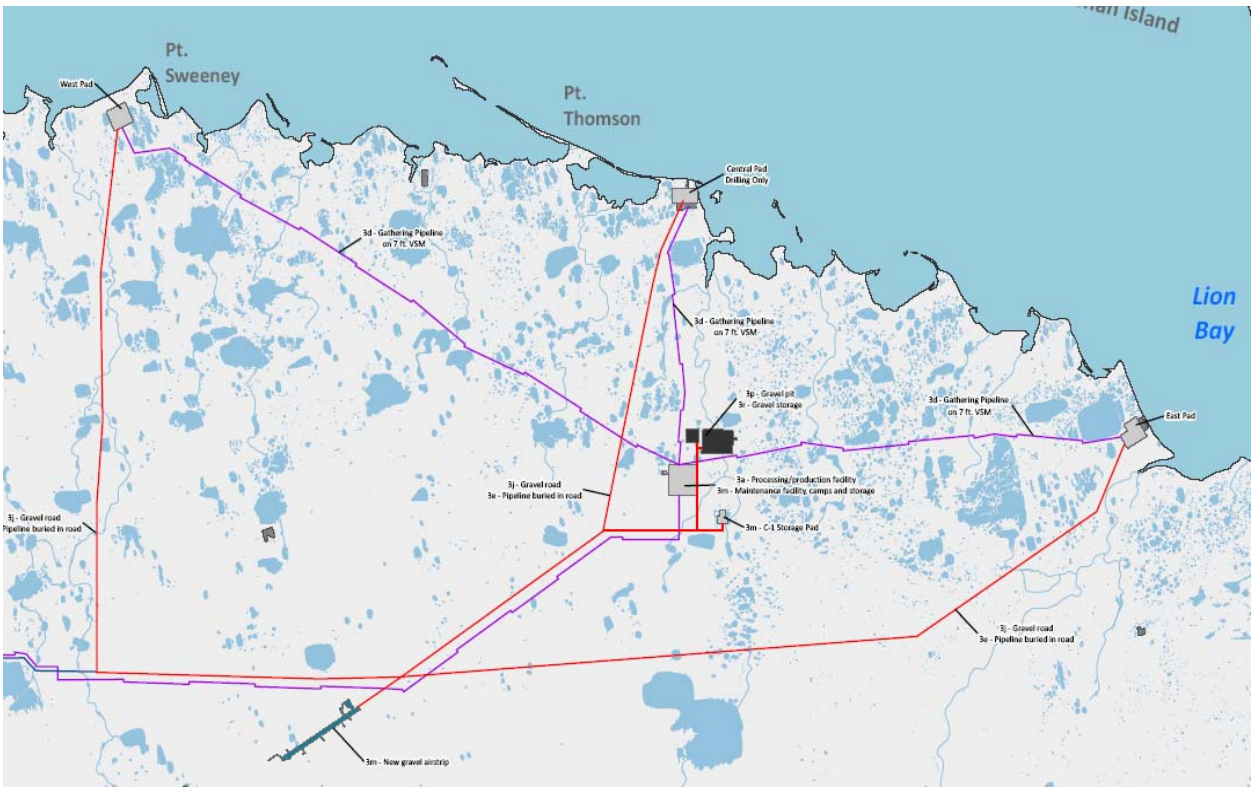

Figure 1 – Alternative 3B Site Layout – Main Features (provided by HDR)

2.2 Pipeline

The main Pipeline features of Alternative 3B are outlined below and also shown in Figures 1 and 2.

- Export Pipeline (refer to Figure 2):
  - Approximately 22 miles of 12” export pipeline constructed on Vertical Support Members (VSMs) 7-feet above the tundra from Central Processing facility (CPF) to Badami (similar to ExxonMobil’s proposal, however further inland).
  - Pig launcher and custody transfer meter module at CPF
  - Pig receiver and surveillance meter module at Badami
  - Approximately 22 miles of fiber optic cable and power cable from CPF to Badami
  - Control Module at Badami

- In-field pipelines:
  - Gathering (production) lines consisting of 8” heat traced pipelines installed on VSMs 7-feet above the tundra as follows (refer to Figure 1)
    - Approximately 6 miles from the West Well Pad
    - Approximately 4 miles from the East Well Pad
    - Approximately 2 miles from the Central Well Pad
  - Pig launcher and receiver facilities at West, Central, and East Well pads for gathering lines and production line
  - Approximately 6 miles of fiber optic cable and power cable from CPF to West Well Pad
  - Approximately 4 miles of fiber optic cable and power cable from CPF to East Well Pad
  - Approximately 2 miles of fiber optic cable and power cable from CPF to Central Well Pad
- Gas re-injection line (refer to Figure 1):
  - Approximately 2 miles of 10” gas re-injection line, constructed on shared VSMs 7 feet above the tundra from CPF to Central Well Pad

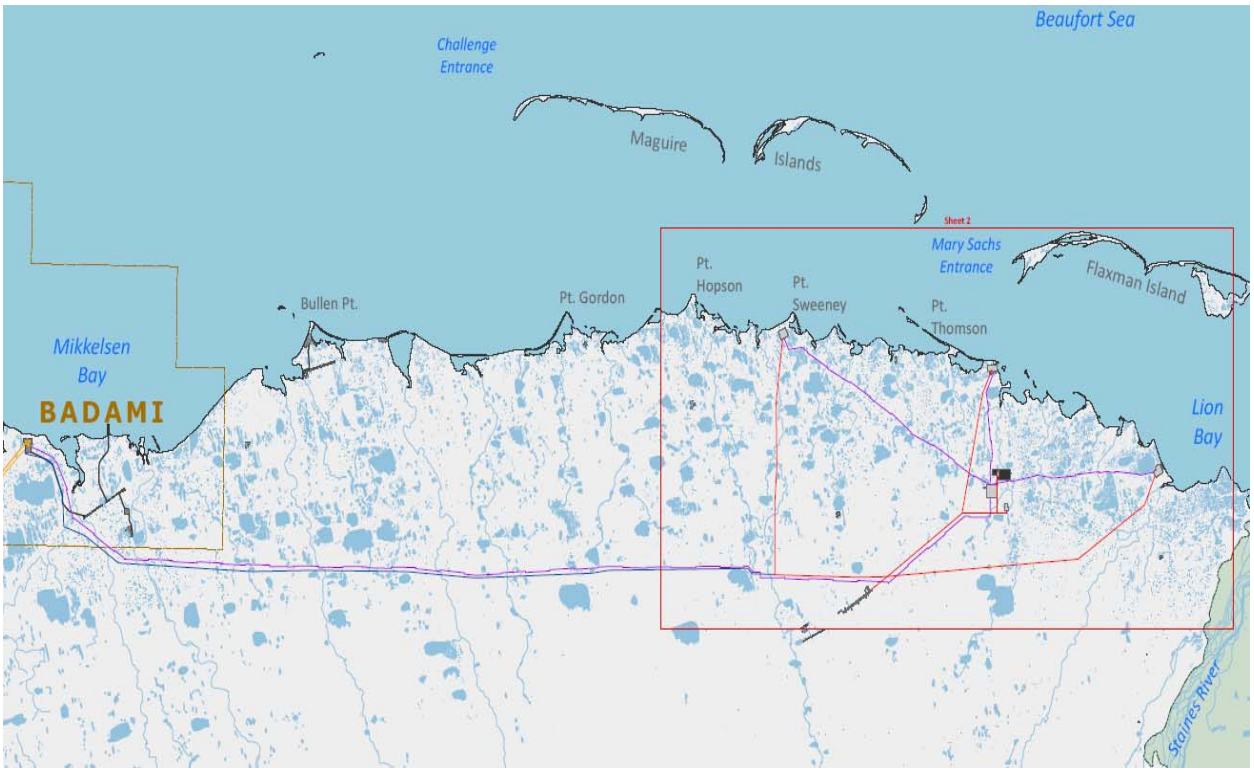

Figure 2 – Alternative 3B – Point Thomson Connection to Badami (provided by HDR)

2.3 Facilities

The main Facilities features of Alternative 3B are outlined below.

- Compression Technology
  - ExxonMobil understands the preliminary 3B Alternative assumed the use of centrifugal compression technology. As described in Practicability of Point Thomson Draft EIS Alternatives, ExxonMobil Technical Brief #2 – Centrifugal Compressors (attached to ExxonMobil Preliminary Response to Point Thompson EIS Draft Alternatives and Components, June 25, 2010), (to be supplemented pursuant to the workshop held on July 29, 2010), ExxonMobil does not believe it would be practicable to use centrifugal compression technology for the Point Thomson Project.
- Module Size
  - Module weights limited to historic proven technology for ice road transportation and not to exceed 1300 tons

- Wells
  - Five production/injection wells and one disposal well located as follows
    - One production and one injection well on the Central Well Pad
    - One production well on the East Pad
    - One production well on the West Pad
    - One additional production well on one of the three well pads
    - One disposal well on the Central Processing Facility Pad

3.0 TIMELINE

3.1 Infrastructure Construction

The processing facilities and pipelines in Alternative 3B would be installed in three separate construction seasons. The first season (Dec. 2013-Dec. 2014) will include ice road installation from Deadhorse to Point Thomson; construction camp installation; mine site development; gravel placement for the Central Processing Facility Pad, airstrip, and the connecting roads; culverts and bridge installation; and infrastructure piling and foundations. The second season (Dec. 2014-Dec. 2015) will include ice road installation from Deadhorse to Point Thomson; gravel for the East and West Well Pads and access roads; culverts and bridge installation; infrastructure piling; mine site closeout and rehabilitation; and buildings and module piling. The third season (Dec. 2015-May 2016) will include ice road installation from Deadhorse to Point Thomson for the movement of the processing modules and module installation and hookup.

3.2 Pipeline Construction

Alternative 3B would be executed in three separate construction seasons. The first season (Jan. 2014 – May 2014) will include ice roads, temporary camp mobilization/ de-mobilization, VSM's for the export pipeline. The second season (Jan. 2015 – Aug. 2015) will have another ice road (work pad) to lay and weld the export line, install fiber optic and power cables, hydrostatically test the pipeline in the summer, install launcher/receiver/meter facilities, and pre-commission the Export Pipeline. The third season (Jan. 2016 – Aug. 2016) will include ice roads, VSMs, lay and weld the infield gathering and gas reinjection lines, install infield power lines and fiber optic cables, install

launcher/receiver facilities, hydrostatically test, and pre-commission the gathering and gas re-injection lines.

Construction crews for the export pipeline will be housed primarily in a remote camp on an ice pad in the vicinity of the Badami unit for the first season and at PT Thomson the second season. Construction crews for the gathering lines will be housed at Point Thomson.
As with the applicant's proposed case and the other alternatives the VSMs will be pre-fabricated off of the North Slope and delivered to the construction ice road by truck. The pipe sections will be double jointed (two joints welded together), Fusion Bond Epoxy coated and insulated in Fairbanks, loaded and delivered to the North Slope by the pipeline installation contractor or his sub contractor.

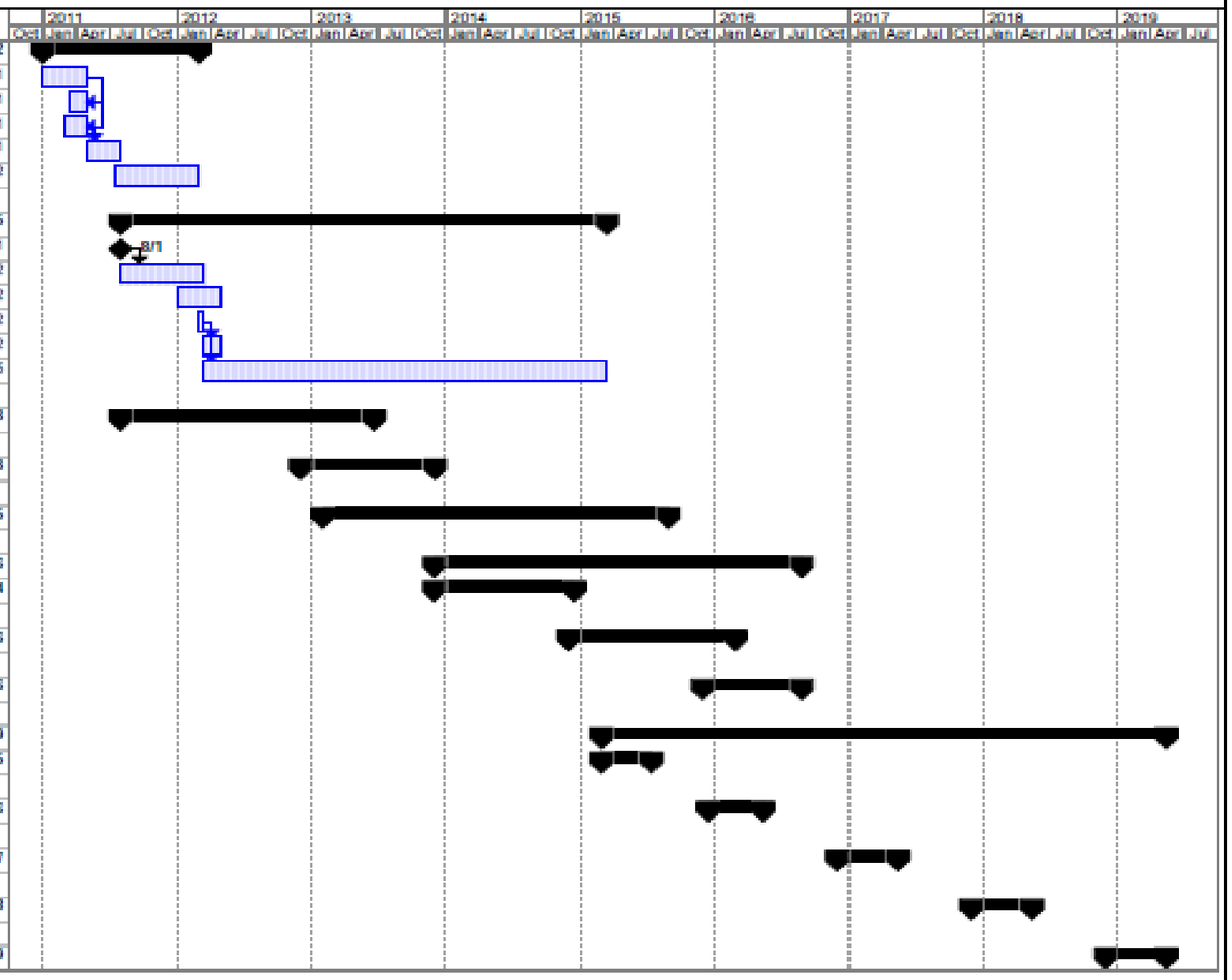
3.3 Facilities Construction

The Facility modules will be fabricated off the North Slope and sea lifted to Prudhoe Bay via ocean going barges during the 2015 summer season. The modules will be offloaded at Prudhoe Bay West Dock and temporarily stored in the Deadhorse area. A tundra ice road will be built from Endicott to Point Thomson during the 2015-16 winter season allowing the modules to be transported to the Point Thomson Site in 1-2Q 2016.

Construction crews will be housed primarily at Point Thomson to allow for infrastructure foundations, hook-up and commissioning activities to commence when the modules arrive for an expected facility startup by year end 2016.

3.4 Drilling

The well work for Alternative 3B would take place over five years, with the drilling rig (rig) being demobilized over ice roads during the sixth season (March 2020). A rig would be mobilized during the spring of 2015 over ice roads, along with all of the supplies and materials needed to drill the disposal well. The equipment associated with the Grind and Inject facility would also be mobilized at this time. The disposal well would be drilled and completed by late spring. The Grind and Inject facility would be installed that summer.



The following ice road season (2016), the rig would be moved to the Central Well pad and resupplied. PTU #15 and 16 would be completed. This would carry into the summer.

During the third ice road season (2017) the rig would move to the East Well Pad, be resupplied and drill the next well. This pattern would be repeated for the next two years to complete all five development wells.

4.0 SUMMARY OF CIVIL WORKS AND PIPELINES

4.1 Infrastructure

ALTERNATIVE 3B ESTIMATED CIVIL WORKS

	Item	Quantity
Infield Roads (21 miles x 32')	Gravel Road	152 Acres/1,550,000 CY
	Culvert	200-300

	Item	Quantity
Ice Road Access to Point Thomson	Season 1	75,000,000 Gallons
	Season 2	75,000,000 Gallons
	Season 3	75,000,000 Gallons

	Item	Quantity
Gravel Mines	Gravel Mine (Infield Roads-Pads)	3,300,000 CY

	Item	Quantity
Gravel Pads	East Drill Pad	18 Acres/208,000 CY
	West Drill Pad	18 Acres/280,000 CY
	Central Drill Pad	15 Acres/230,000 CY
	Facilities Pads	35 Acres/500,000 CY

	Item	Quantity
Airstrip	Gravel Airstrip	475,000 CY

4.2 Pipeline

ALTERNATIVE 3B PIPELINE DATA		
Export Pipeline Condensate (from CPF to Badami)	**Item**	**Descriptions**
	Design Code	ASME B. 31.4 and 49 CFR Part 195
	Length	Approx 22 miles
	Outside Diameter	12.75 inch
	Design Flowrate	70,000 bpd
	Design Pressure	2035 psig
	Material	Carbon Steel

East and West Gathering Line (from East/West Pad to CPF)	**Item**	**Descriptions**
	Design Code	ASME B. 31.8
	Length	East approx 4 miles, West approx 6 miles
	Outside Diameter	8.625 inches
	Design Flowrate	200 Mscfd
	Design Pressure	8800 psig
	Material	Duplex 2205

Production Gathering Line (from Central Pad Drilling to CPF)	**Item**	**Descriptions**
	Design Code	ASME B. 31.8
	Length	approx 2 miles
	Outside Diameter	8.625 inches
	Design Flowrate	200 Mscfd
	Design Pressure	8800 psig
	Material	Duplex 2205

Gas Re-injection line (from CPF to Central Pad Drilling)	**Item**	**Descriptions**
	Design Code	ASME B. 31.8
	Length	approx 2 miles
	Outside Diameter	10.75 inches
	Design Flowrate	200 Mscfd
	Design Pressure	12,000 psig
	Material	Carbon Steel

5.0 IMPACTS

5.1 Facility

Alternative 3B requires utilizing the existing Prudhoe Bay West Dock in-field gravel roads to Deadhorse, and existing gravel storage pads in the Prudhoe Bay area. It may require widening the gravel roads and expanding the gravel pads. Tundra ice roads are built for transporting facility modules from Deadhorse to Point Thomson. Based on previous projects the maximum module weight transported on an ice road was approximately 1300 tons. If for any reason, a tundra ice road is not feasible, then portions of a sea ice road would need to be constructed. The sea ice road would need to be grounded to the sea bottom its entire length which would require agency approval for fish passage at the mouth of the three river crossings. Initial screening was conducted for this conceptual scenario to revise the number of modules needed to provide the identical process capability based on the historic maximum module weight and resulted in an increase in the number of facility modules from the base case by a factor of three to four.

An additional six months for re-engineering would be required to make the necessary changes to the FEED (Front End Engineering Design) effort based on the alternative's module weight constraints. Additional detailed engineering would be required before procurement and module fabrication could begin leading to a minimum one-year delay in module shipment (summer 2015 vs. 2014). This delay combined with the need to stage the modules in Deadhorse for ice road delivery in the winter of 2015-16 would lead to a minimum two year delay in start-up. Refer to Table 1 – Conceptual Scenario - Level 1 Timeline for Alternative 3B. The delay would result in the project site requiring care-taker activities and maintenance of temporary facilities for the first two years to accommodate construction startup from 2012 to 2014. These first two years will have an impact on logistics both air and land, as well as associated power generation, solid and liquid waste generation and handling, vehicular traffic, road and pad maintenance. Ice roads may have to be built each year to maintain safe access and for resupply.

The installation man-hours (on the North Slope) for the process facilities are estimated to be more than double the base case because there are more components that must be

interconnected in the field. Similarly, it is estimated that 50% more man-hours would be needed to achieve functional check-out and systems completion because there are more components that must be interconnected in the field.

The overall tundra take would likely increase if drilling rig space is required at both the Central Well Pad and the Facilities Pad for the disposal well. The larger number of process modules with the minimum required safe space between and around them will require a larger area. Further study is required to assure sufficient lay-down space for construction, drilling and operations. The number of support piles under the modules and pre-assembled units are expected to more than triple from the base case.

5.2 Pipeline

Moving the Central Processing Facility 2 miles south of the Central Drilling Pad results in two additional in-field pipelines (8” gathering line and 10” gas re-injection line). These two additional pipelines increase the possible total spill volume, and require additional manpower, equipment, and camp space to construct. These two pipelines also result in the addition of pipeline facilities, and a pig launcher and pig receiver for the gathering line, fiber optic cable, and power cable between Central Processing Facility and Central Well Pad.

Crossing the road at Badami and bringing the export pipeline on to the east side of Badami’s central pad causes additional interfaces between pipelines, production, and drilling. The additional interfaces raise further issues which would need to be addressed. The east side is the path where rigs are brought in so the pipeline must be buried in a manner that is both rig rated yet not thaw the permafrost. This is also the location where drilling camps are placed. The pipeline must also be routed through production and process equipment. ExxonMobil’s proposed pipeline route avoids these interfaces and issues by coming onto the west side of the central pad where all of Badami’s export pipeline facilities are located.

5.3 Wells

Without barging support, all major equipment and material mobilization and resupply must occur during the ice road season or by air once the infield roads are in place. In order to

have the disposal well available for first production and have both producing wells available, a rig would be mobilized during the spring of 2015 over ice roads, along with all of the supplies and materials needed to drill the disposal well. The equipment associated with the Grind and Inject facility would also be mobilized at this time.

The disposal well would be drilled and completed immediately after rig mobilization. The disposal well would not be completed until after the loss of ice roads to Deadhorse, so the rig would be stacked on the Central Production Facility Pad until the winter of 2015. At that time it would be moved over infield roads to the Central Drilling Well Pad and PTU 15 and 16 wells would be completed. This would be timed in such a way that the first completion could be supplied by rolligon, prior to completion of ice roads. The second completion would then be resupplied by ice road and would continue into the summer months.

At the beginning of the next ice road season, the rig would be moved by infield roads to the East Well Pad and readied for drilling. The rig could be moved essentially anytime over the local gravel roads. This time is chosen for maximum crew efficiency. The rig would be resupplied by rolligon and drilling would commence as early in the season as possible to allow reaching total depth prior to the April 15 seasonal restriction. The disposal well could be used to expedite the handling of waste products from this well. Because of the length of the Point Thomson wells, the completion of a single well would carry the operation beyond the ice road season. While the rig could be moved from pad to pad, the supplies needed to drill the next well could not be obtained until the next ice road season, unless they were resupplied by Hercules aircraft. For the sake of this discussion, we have simply used the ice road alternative. In reality a detailed cost/benefit analysis would be done to determine the most cost effective operation.

As shown on the attached schedule, the drilling would progress in this manner; drilling one well a year until the program is completed. The fifth well would carry into the summer of the fifth season. The rig would then be demobilized by ice road during the sixth season.

5.4 Logistics

Alternative 3B

- The limitation of having no summer coastal barging resupply to support current schedule and plans for construction of the facilities and infrastructure will require reliance on winter ice roads only and continued transport of personnel by helicopter / aircraft until the gravel airstrip is in place during non-ice road months.
- Large staging and storage areas will need to be acquired or constructed to enable the marshalling of materials and equipment ready to take advantage of the ice road season.
- The volume of trucks and trailers will be limited and require time to obtain with existing available transport companies in Alaska that have suitable equipment for ice road transport.
- Urgent resupply and materials transport will require additional helicopter support and flights between Deadhorse and Point Thomson when ice roads are not available. The helicopter traffic will be offset and assisted by fixed wing aircraft for material and small equipment flights after the completion of the permanent gravel air strip near the Point Thomson Site.
- Using only ice roads for the transport of materials and equipment for construction and drilling support, including supplies for ongoing operations, will limit the volume of shipments due to the narrow time frame for usable ice roads.
- The limitation of having only ice road and air transport support to logistics results in a longer construction and drilling schedule for additional years to complete the proposed work.

Module Transport:

- Transport from Prudhoe Bay to Point Thomson will require more numerous and smaller modules. Based on previous projects the maximum module weight transported on an ice road was approximately 1300 tons. There will be a need to design and utilize multi-wheel transport trailers and vehicles able to spread the load and wheel bearing on the ice road for transport. The number of modules, interconnecting materials, piles, etc. will increase ice road trucking trips and increase exposure to wildlife encounters.

- The smaller size modules will require more onsite hook-up and commissioning work at Point Thomson. This will require the transport and housing of larger work forces, larger camps, more resupply and possibly a longer construction schedule extending the length of time to complete the construction and startup.

6.0 ISSUES

This is a very preliminary screening study for purposes of EIS alternative comparison and is based upon the best professional judgment of the individuals involved and collective knowledge and experience as detailed in the Section 1.0. Due to the limited definition of the alternative and limited time available for evaluation, there are a number of critical issues which were not and could not be fully addressed. This section is intended to identify the more significant issues that would need further evaluation before the alternative could be capable of being implemented in the estimated timeframe.

6.1 Infrastructure

Geotechnical Investigation:

- Requires a geotechnical investigation for the road route, all bridges, and mine site.

Hydraulics/Hydrology Study:

- Requires a hydraulics and hydrology study for all bridges, culverts and roadway. As part of this study, breakup and ice characteristics should be determined.

Survey:

- Requires route survey as well as detailed topography at bridge crossings for final alignment.

Centrifugal Compressors

- Refer to Practicability of Point Thomson Draft EIS Alternatives, ExxonMobil Technical Brief #2 – Centrifugal Compressors (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010).

6.2 Pipeline

Field Data Gathering:

- This alternative is located further south of the original export pipeline and gathering lines route, therefore additional centerline survey, hydrology data, and geotechnical data gathering will be required to complete detail engineering design. Geotechnical data gathering for rivers and road crossings needs to be performed in winter 2011, while the river spring breakup data and centerline survey need to be performed by the summer of 2012 to ensure the pipeline detail engineering can be completed by January, 2013. Any slippage to the field data gathering schedule will impact the overall pipeline construction completion.

Gathering Lines issues:

- This alternative also separated the Central Well Pad from the Central Processing Facility, therefore operational issues related to two miles of production lines and gas re-injection line will have to be identified and addressed such as having to manage events arising from plant shutdowns with resulting product cooling and potential formation of hydrates blocking the line. The additional pipeline length will amplify operational issues considerably.

6.3 Facilities

Module Size:

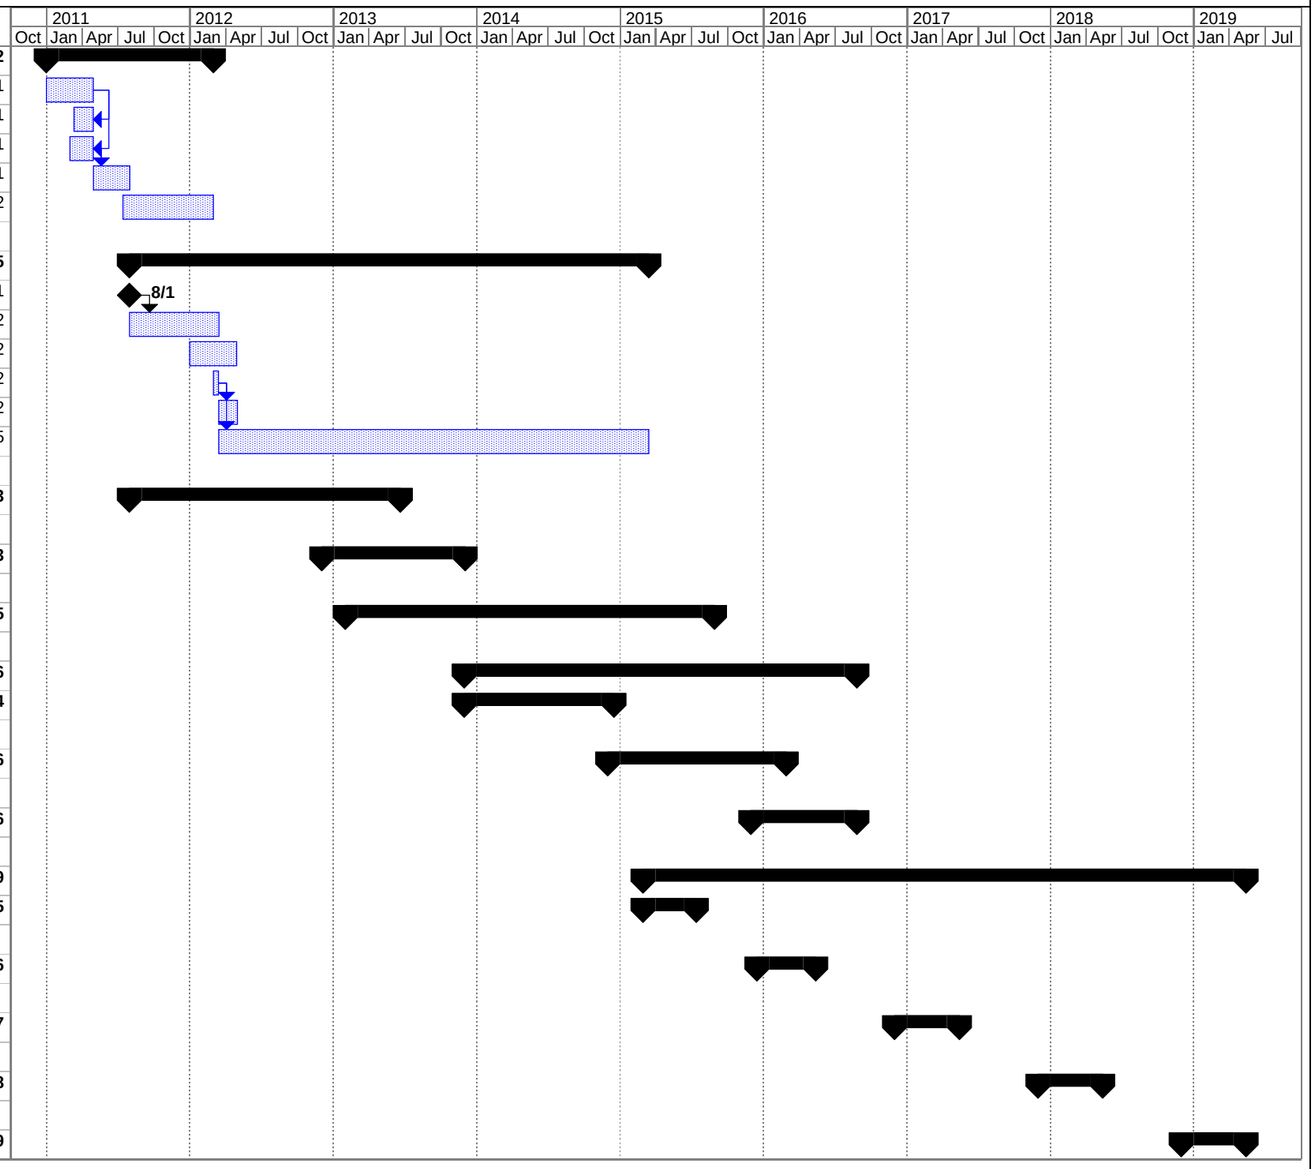
- Alternative 3B changes the module size envelope and as such the modularization criteria will have to be reexamined. The smaller and lighter modules will create issues pertaining to the level of details of the interconnections between the various modules. Significant inefficiencies will also be created due to the splitting of modules with shared equipment such as the compressors that have shared process equipment and the generators with the shared waste heat recovery unit. Increasing the maximum module weight beyond the previously proven 1300 tons would require feasibility studies to examine ice road capacities as well as ice road detours and crossings of rivers/streams. Results will have to be incorporated in the design.

Processing Facility Pad Location:

- Moving the Central Processing Facility Pad further south increases the distance between the wellheads and the facility. Further studies need to be conducted to address the implications on the facility design and pipeline route due to the addition of 2 miles of very high pressure heavy wall gas injection line.

Well Pad Locations:

- Refer to Practicability of Point Thomson Draft Alternatives, ExxonMobil Technical Brief #1- Well Pad Locations (attached to ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components, June 25, 2010).



6.4 Wells

Drilling Program:

- The primary impact of the 3B Alternative on the drilling program is that of extending the schedule due to the loss of barging support. This restricts resupply activities to the ice road season, or requires air support. Compared to ExxonMobil's proposal, nine months is added to the time required to drill the disposal well and complete the PTU 15 and 16 wells. For the entire program (drilling the disposal well, completing the two current wells, and drilling three new wells) what could previously be accomplished in three years would now require six years, including rig demobilization.

1.0 INTRODUCTION

At the request of HDR and the EIS agencies during workshops on July 12, 2010, and in order to expedite further development of potential alternatives to ExxonMobil's (Applicant) proposed Point Thomson Project that would be analyzed in the EIS, ExxonMobil has prepared conceptual project scenarios for three alternatives (3A, 3B and 4). These alternatives were independently formulated by the EIS agencies and HDR without ExxonMobil involvement.

These project scenarios describe the major engineering and construction activities and related schedules for each scenario. Preliminary risks, challenges and issues associated with the alternatives are also identified. These responses supplement ExxonMobil's June 25, 2010 comments to the EIS agencies and HDR with respect to practicability and purpose and need of the proposed alternatives (ExxonMobil Preliminary Response to Point Thomson EIS Draft Alternatives and Components).

Although plans for the alternatives have not been engineered, ExxonMobil has applied the experience and knowledge gained from the three years of engineering and planning expended for the proposed Point Thomson Project (EIS Proposed Action), as well as the current drilling program, to develop scenarios that are reasonable and suitable for environmental impact analysis. This effort relied upon experienced Point Thomson personnel who have used their best professional judgment over the short time frame available to respond.

These scenarios must be distinguished from the extensive, multi-year process of planning and engineering for actual execution of a proposed Project. Because the proposed alternatives are conceptual in nature based on general versus specific goals to mitigate potential impacts (for example, to coastal resources or wetlands), ExxonMobil's scenarios are also conceptual. The potential alternatives at this stage, with some exceptions, lack specificity such as precise locations, sizes, or preferred technical approaches. Likewise in the scenarios all dates, material quantities and the like are very general estimates. ExxonMobil recognizes that the draft alternatives are also subject to refinement through revisions to base case assumptions, substitution of potential components and further screening. Moreover, while these scenarios have not been engineered, ExxonMobil

believes that they provide a sound experiential and practical foundation, sufficient for EIS evaluation.

In this response, ExxonMobil generally has not commented on or identified environmental impacts arising from the alternatives that may be different from the Proposed Action. Similarly, ExxonMobil has not commented on costs or determined the commercial viability of the alternative. It should not be assumed that this alternative which has not been engineered is commercially viable or practicable, nor should this response be understood as ExxonMobil's agreement with the alternative or its components and assumptions. The information provided in these scenarios is intended to assist in impact analysis by the EIS agencies and HDR. ExxonMobil may comment on environmental impacts or costs of the alternatives at appropriate opportunities in the EIS process.

1.1 Comments on Execution Schedules

In the Alternative 4 scenario descriptions below, ExxonMobil has estimated the time required to conduct field studies and engineering would delay the commencement of construction by about one year when compared to Alternative 2, e.g., commencement of construction for Alternative 4 would be delayed until 4Q 2012 vs. 4Q 2011 for Alternative 2 (please see section 5.1 for more details). For this reason, Alternative 4 does not meet the Project's purpose and need with respect to ExxonMobil's commitment to the State of Alaska for production in 2014.

Alternative 4 requires redesign and expansion of the Central Production Facility (CPF) Pad to provide additional storage, which is expected to delay the initial construction season from the winter of 2011-2012, to the winter of 2012-2013. However, from that point forward the construction process would likely substantially follow ExxonMobil's current proposal and schedule for construction of infrastructure, pipelines and facilities, but with start-up in late 2015.

Once production has been initiated, there would be increasingly significant divergences from the Applicant's proposal due to short and long term effects on the planned drilling and logistics schedule, conduct of facility and well operations, and emergency response capability arising from the absence of in-field roads to the East and West Pads. These and other important long term considerations are addressed below in a general fashion.

Note: Definition of 'Seasons'

'Seasons' in the following sections refers to a period of time where a specific activity or group of activities (ice road installation, pipeline installations, facilities, infrastructure, or drilling, etc.) takes place. On the North Slope, most construction work occurs during the 'winter season', which generally includes portions of two calendar years. The activities included in a 'Season' vary from one activity to another (e.g. construction vs, drilling) and one season to the next, and a season may be part of a calendar year or it may be comprised of the end of one calendar year and the beginning of the next. For clarity, the duration of a season in a specific context is set out in a parenthetical giving the months and year[s] involved, and is also shown for each year and each activity on the schedule.

2.0 DESCRIPTION OF ALTERNATIVE 4

This section summarizes ExxonMobil's understanding of the principal features of the base case for Alternative 4. These assumptions have been clarified and confirmed by HDR as a step in the development of the conceptual scenarios. Please note that these assumptions have been modified from those relied upon by ExxonMobil in its June 25th practicality response. However, there are additional execution and operational knock-on effects, which are not predictable at this time and will require further detailed analysis. Also, in order to focus the input of the appropriate engineering and execution teams, the principal features of this Alternative have been further categorized into the major project scopes of Infrastructure, Pipeline, Drilling and Facilities. A full analysis will require that differences in operations also be considered but that is beyond the scope and timeframe available for this initial response.

2.1 Infrastructure

The main Infrastructure features of Alternative 4 are outlined below and also shown in Figures 1 and 2.

- Gravel Roads:
  - Airstrip, gravel pit and existing storage pad (C-1) to be connected to the Central Pad (CP) by a gravel road (32' wide at crown x 5 ft deep)
- Tundra Ice Roads (seasonal):

  - Tundra ice road between the Prudhoe Bay area and Point Thomson for construction re-supply
  - Infield tundra ice roads connecting the East and West Pads to the Central Pad)
- Gravel Pads:
  - Central Pad – assumes an expansion by approximately 21 acres (681,000 CY) contains drilling, process facilities, camp, warehouse, Class I disposal well, additional storage, and helipad and associated aviation systems
  - East and West Well Pads – gravel pad sized to accommodate workover / wireline rig, permanent facilities, as well as year-round helicopter access
- Ice Pads (multi-year)
  - East and West Well Pads – ice pad extensions to gravel pad to support the drilling phase
- Airstrip:
  - Gravel airstrip located 2 miles south of the Central Pad
  - Airstrip design and footprint optimized for a Twin Otter type of aircraft (3700’ x 170’ approx), with an ice extension of the airstrip on an as needed basis
- Barge Offload Facility/Barging
  - Module offloading at Point Thomson
  - Coastal barging offload facility for logistical support
- Gravel pit / Water source
  - Point Thomson area gravel pit/water source co-located with airstrip

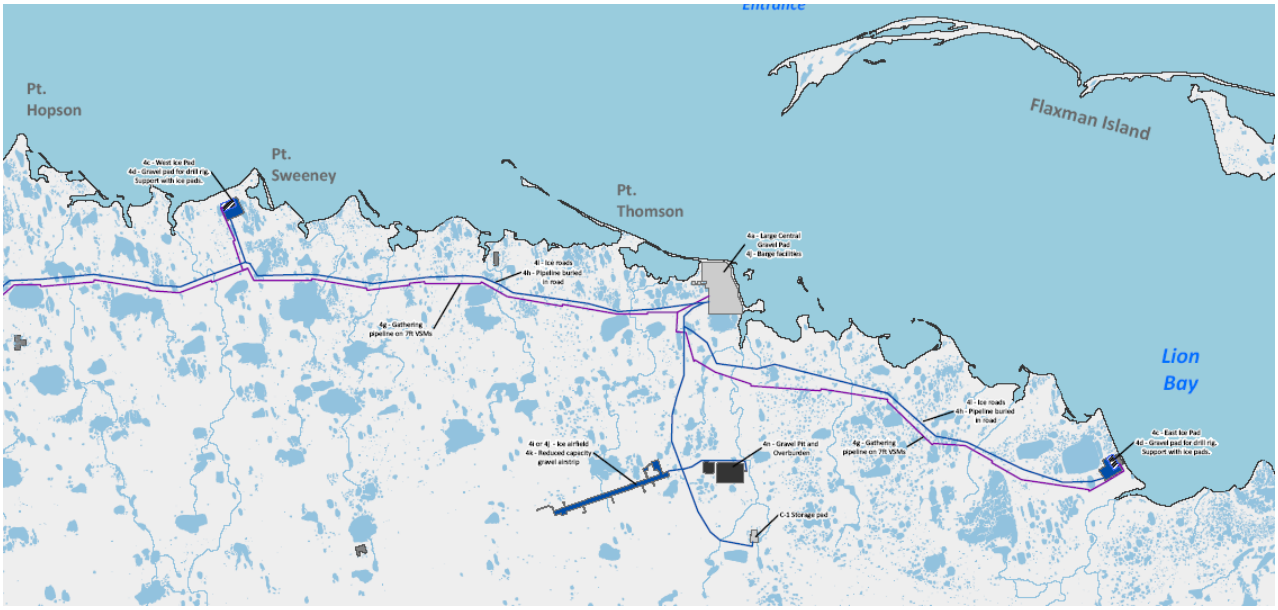

Figure 1 – Alternative 4 Site Layout – Main Features (provided by HDR)

2.2 Pipeline

The main Pipeline features of Alternative 4 are outlined below and also shown in Figures 1 and 2.

- Export Pipeline (refer to Figure 2) (similar to Applicant's proposal):
  - Approximately 22 mile of 12" export pipeline constructed on Vertical Support Members (VSMs) 7-feet above the tundra from Central Pad to Badami
  - Pig launcher and custody transfer meter module at the Central Pad
  - Pig receiver and surveillance meter module at Badami
  - Approximately 22 miles of fiber optic cable and power cable from Central Pad to Badami
  - Control module at Badami
- In-field pipelines (similar to Applicant's proposal):
  - Gathering (production) lines consisting of 8" heat traced pipelines installed on VSMs 7-feet above the tundra as follows (refer to Figure 1)
    - Approximately 5 miles from the West Well Pad
    - Approximately 5 miles from the East Well Pad
  - Pig launcher and receiver facilities at the Central and East and West Well pads for gathering lines

- Approximately 5 miles of fiber optic cable and power cable from Central Pad to West Well Pad
- Approximately 5 miles of fiber optic cable and power cable from Central Pad to East Well Pad

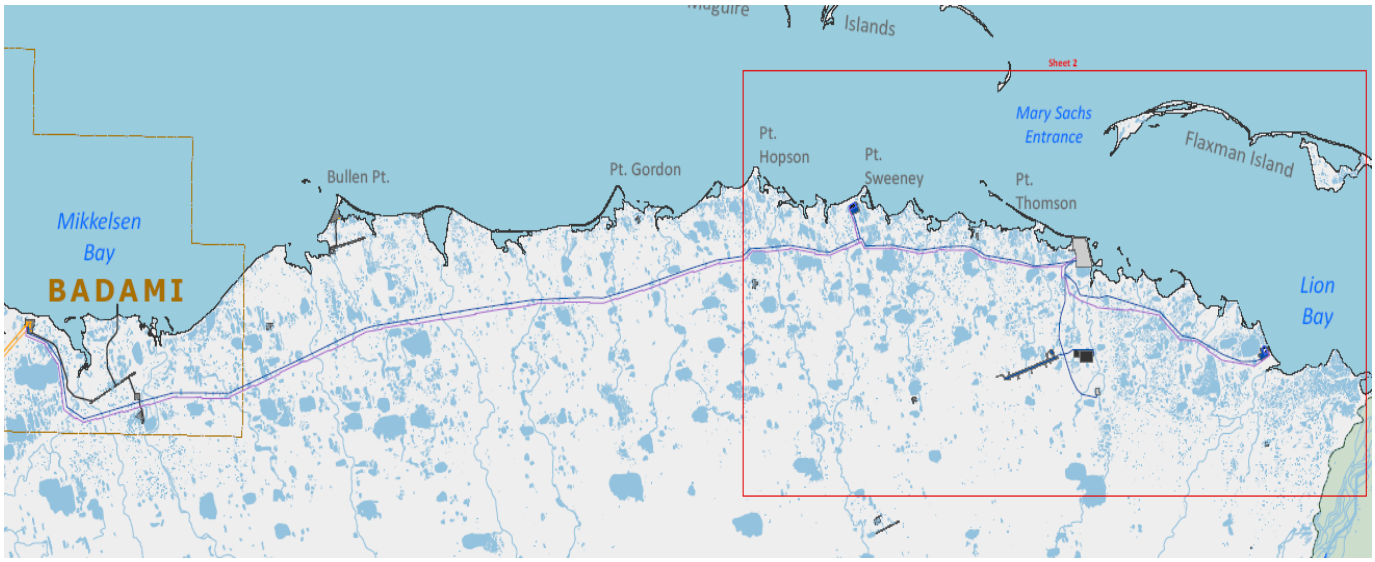

Figure 2 – Alternative 4 – Point Thomson Connection to Badami (provided by HDR)

2.3 Facilities

The main Facilities feature of Alternative 4 is outlined below:

- Compression Technology
  - Production processing using reciprocating compression technology

2.4 Wells

- Five production/injection wells and one disposal well located as follows
  - One production, one injection and disposal well on the Central Pad
  - One production well on the East Well Pad
  - One production well on the West Well Pad
  - One additional production well on one of the three pads

3.0 TIMELINE

3.1 Infrastructure Construction

The processing facilities and pipelines in Alternative 4 would be installed in three separate construction seasons. The first season (Dec. 2012 – Nov. 2013) will include ice road installation from Endicott to Point Thomson; construction camp installation; gravel pit and overburden site development; gravel placement for the Central Processing Facility Pad, airstrip, and the connecting roads to the gravel pit and storage pad site; culverts and marine facilities; and infrastructure piling and foundations. The second season (Dec. 2013 - Dec. 2014) will include ice road installation from Endicott to Point Thomson; gravel for the East and West Well Pads, infrastructure piling; gravel pit site closeout and rehabilitation; installation of the permanent camp and some non-process facilities and module piling. The third season (Dec. 2014 – Dec. 2015) will include ice road installation from Endicott to Point Thomson, construction of the multi year ice pads at both the East and West Well Pads, and infrastructure work at the Central Pad in preparation for the module installation and hookup.

3.2 Pipeline Construction

Alternative 4 would be executed in three separate pipeline construction seasons. The first season (Dec. 2012 – May 2013) will include ice roads, temporary camp mobilization / de-mobilization, and installation of VSM's for the export pipeline. The second season (Jan. 2014 – Aug. 2014) will have another ice road (work pad) to lay and weld the export line, install fiber optic and power cables, hydrostatically test the export pipeline, install and pre-commission the launcher/receiver/meter facilities for the export pipeline. The third season (Jan. 2015 – Aug. 2015) will include ice roads, VSMs, lay and weld the infield gathering lines, install infield power lines and fiber optic cables, install launcher/receiver facilities, and hydrostatically test the gathering lines.

Construction crews for the export pipeline will be housed primarily in a remote camp on an ice pad in the vicinity of the Badami Unit for the first season and at Point Thomson the second season. Construction crews for the gathering lines will be housed at Point Thomson.

As with the applicant's proposed case and the other alternatives, the VSMs will be pre-fabricated off the North Slope and delivered to the construction ice road by truck. The pipe sections will be double jointed (two pipe sections welded together), required non-destructive examination (NDE) completed, Fusion Bond Epoxy coated and insulated in Fairbanks, loaded and delivered to the North Slope by the pipeline installation contractor or his sub contractor.

3.3 Facilities Construction

The Facility modules will be fabricated off the North Slope and sea lifted directly to Point Thomson via ocean barges during the summer season of 2015. The modules will be offloaded via a barge bridge concept and using Self Propelled Modular Transporters to set the modules in place. Construction crews will be housed primarily at Point Thomson to allow for facilities and hook-up and commissioning activities to commence when the modules arrive for an expected facility startup by year end 2015.

3.4 Drilling

The well work for Alternative 4 would take approximately five years as outlined in Section 5.2. A drilling rig (rig) would be mobilized during the winter season of Feb.– Mar. 2014 over ice roads, along with well control equipment, and all of the supplies and materials needed to drill the disposal well and to complete the first producing well. The equipment associated with the grind and inject facility would also be mobilized at this time. The disposal well would be drilled and completed by late spring. The grind and inject facility would be installed that summer of 2014. Drilling operations would continue on the Central Pad, completing both currently drilled wells (PTU-15 and PTU-16) before November 2014.

The rig would likely be demobilized by ice road in the following winter season (2018-2019), or possibly by barge in the summer of 2018 or 2019 (depending upon at which pad it was located) if there were no other need for an ice road to Endicott. By the time the rig was demobilized, the drilling campaign will have lasted roughly five and a half years.

4.0 SUMMARY OF CIVIL WORKS AND PIPELINES

4.1 Infrastructure

ALTERNATIVE 4 ESTIMATED CIVIL WORKS		
Gravel Road (2.95 miles x 32')	**Item**	**Estimated Quantity**
	Gravel Road	21 Acres/170,000 CY
	Bridge < 100'	1 ea
	Culvert	25-35 ea

Gravel Pads	**Item**	**Quantity**
	East Well Pad	11 Acres/110,000 CY
	West Well Pad	11 Acres/110,000 CY
	Central Pad	70 Acres/681,000 CY

Airstrip (3700'x170')	**Item**	**Quantity**
	Gravel Airstrip	525,000 CY

Gravel Pits	**Item**	**Quantity**
	Gravel Pit	1,300,000 CY

Ice Roads and Pads	**Item**	**Quantity per season**
	East Well Pad Ice Road	5,500,000 Gallons
	West Well Pad Ice Road	5,500,000 Gallons
	East Well Pad	13,000,000 Gallons
	West Well Pad	13,000,000 Gallons

4.2 Pipeline

ALTERNATIVE 4 PIPELINE DATA		
Export Pipeline Condensate (from CPF to Badami)	**Item**	**Descriptions**
	Design Code	ASME B. 31.4 and 49 CFR Part 195
	Length	Approx 22 miles
	Outside Diameter	12.75 inch
	Design Flowrate	70,000 bpd
	Design Pressure	2035 psig
	Material	Carbon Steel

East and West Gathering Line (from East/West Well Pad to CPF)	**Item**	**Descriptions**
	Design Code	ASME B. 31.8
	Length	East approx 5 miles, West approx 5 miles
	Outside Diameter	8.625 inches
	Design Flowrate	200 Mscfd
	Design Pressure	8800 psig
	Material	Duplex 2205

5.0 IMPACTS

5.1 Facilities

Alternative 4 delays the fabrication of the process modules to meet a 2015 summer barging season as compared to Alternative 2 (Applicant's Proposal), which supports a 2014 summer barging season. This is directly related to the one year delay in the construction season from 4Q 2011 until 4Q 2012 due to the necessity of a number of additional summer field studies and engineering required for the Central Pad. Therefore, the supporting facilities for the process modules, including pipeline, will also be delayed a year and the non-process facilities would require the year of 2014 for North Slope construction and hook-up. This will not be able to support the process modules arriving during summer of 2014 for year end start-up.

The first drilling season does not commence until 2014 and the amount of work required to support both drilling and North Slope construction of the non-process facilities does not allow for the process modules to be barged and installed during 2014. The combined effort of logistical support and simultaneous operations creates additional constraints that impair the 2014 process module barging and hook-up.

This one year construction delay would result in the project site requiring care-taker activities and maintenance of temporary facilities for the first year to account for construction startup delay from 4Q 2011 until 4Q 2012. This will have additional impacts on both air and land logistics, as well as associated power generation, solid and liquid waste generation and handling, vehicular traffic, road and pad maintenance.

5.2 Wells

A drilling rig (rig) would be mobilized during the 1Q of 2014 over ice roads, along with all of the supplies and materials needed to drill the disposal well and complete the first producing well (PTU-15). The equipment associated with the grind and inject facility for well cuttings would also be mobilized at this time.

The disposal well would be drilled and completed immediately after rig mobilization. The disposal well would not be completed until after the loss of ice roads to Endicott, so the

supplies and materials for drilling and completing the disposal well as completing the first producing well, would need to be stockpiled on the Central Pad prior to the loss of ice roads. The PTU-15 well would be completed from May into July 2014 and the location would be re-supplied by barge to allow the injection well (PTU-16) to be completed by mid-October, 2014. After completing this well, the rig would be stranded and placed into standby mode until the next season's ice road is available to move it.

In early 2015, once infield ice roads are complete, and the multi-year ice pad built, the rig would be moved to (for the purpose of this exercise) to the West Well Pad and re-supplied by inefficient rolligons and ice road. The surface and intermediate holes of the third producing well would be drilled by early April, 2015. Due to the seasonal drilling restrictions, the production hole could not be drilled at this time. The rig would then be moved to the East Well Pad. However, work could not continue at this time due to the imminent loss of ice roads and logistical capabilities. Drilling of the next surface hole would generate 6000-8000 bbls of cuttings and fluid waste, and these fluids could not be handled without access to the grind and inject facility at the Central Pad.

To expedite an early start, supplies would be brought to the Central Pad during the barging season. These supplies could not be delivered to the East Well Pad until infield ice roads are constructed in the 1Q of 2016.

In 1Q 2016 (3rd ice road season for drilling) work would begin on well #4, drilling the surface, intermediate and production holes. This well would be cased by early April, 2016. There would not be enough time to move back to the West Well Pad and drill Well #3's production hole before the spring thaw. Operations would continue on Well #4, completing and testing it by early to mid-May of 2016. Adequate tankage should be available to cover this operation even if ice roads are lost by this time.

During the fourth drilling season (winter of 2016-2017), local ice roads would be built and re-supply accomplished using inefficient rolligons and ice roads from Endicott. The rig would move back to the West Well Pad (Well #3) to drill and case the production hole by late February and continue with completion and testing, finishing this by late March, 2017. The rig would be moved at this time to the fifth well (pad location to be determined), but

operations would not continue due to the impending loss of ice road support. The rig would be on standby until the next season.

In the fifth drilling season (winter of 2017-2018), Well #5 would be drilled from surface to total depth and completed and tested by early to mid-May. It is unlikely that the rig could be moved from this pad back to Deadhorse at this late date, therefore the rig would be stranded and again placed in standby mode. It would likely be demobilized by ice road in the following winter season (2018-2019), or possibly by barge in the summer of 2018 or 2019 (depending upon at which pad it was located) if there were no other need for an ice road to Endicott. By the time the rig was demobilized, the drilling campaign will have lasted roughly five and a half years.

Drilling Program's schedule is inherently inefficient and will take a total of five and a half years which is about twice as long as industry norms for similar conditions. Should multiple additional wells be drilled as part of a reasonably foreseeable future development, these inefficiencies could be increased and might require later consideration of rig-capable roads.

5.3 Logistics

Sealift Barge Offload Abutment and Sealift Barging:

- The availability of the sealift barge transport and a sealift module capable offloading abutment at Point Thomson will allow the Applicant's full size module deliveries. This allows for the delivery of up to 4000 ton modules directly to the Point Thomson Central Production Facilities Pad.

Coastal Barge Offload Abutment and Coastal Barges:

- Each year, the ability to transport materials, equipment, fuel and other supplies by barge during the Mid-July to end of August barge season, enables re-supply and transport during this 6 – 8 week period of time, therefore resulting in less demand for trucking and traffic on the ice road during the February to May timeframe.

Tundra ice road:

- Tundra ice road transport from Endicott to Point Thomson allows for continued transport of materials and equipment approximately February through April each year.

Enlarged Central Facility Pad and reduced East and West Well Pads with ice road interconnect:

- Not having infield gravel roads connecting the East and West Well Pads with the Central Pad will require primary dependence upon helicopters for routine access to the pads and limit the ability to maintain and perform any work in preparation of the Pad and or movement of any structures or equipment on these Pads.
- Emergency response access, relief and evacuation requirements for personnel would need to be considered given the lack of year round access and demonstrated record of no fly days due to weather. Weather related grounding of helicopters can be up to a week or more.
- Pre-staging will need to be performed at the Central Pad in anticipation of any move to work at these East or West Well Pads.

Reduced sized gravel airstrip and gravel connecting road:

- The abbreviated gravel airstrip (3700' X 170') will limit the available aircraft suited for people and cargo transport to Point Thomson.
- Providing personnel and cargo transport prior to constructing the airstrip and connecting gravel road will be accomplished by charter and commercial flights to Deadhorse and then helicopter and / or bus transport during ice road season.
- After completion of the gravel airstrip and ILR / GPS landing capabilities, the transport of the construction personnel would need to continue to be transported to Deadhorse, then on to Point Thomson, via the gravel airstrip by approved smaller aircraft capable of safe landing and takeoff from the shorter airstrip. This will eliminate the efficiencies of the Applicant's intended larger aircraft transport from Anchorage directly to Point Thomson without the need for the landing and aircraft change in Deadhorse. The use of the smaller sized aircraft may require as many as twice the take-offs and landings to transport the same numbers of personnel with the 'Twin Otter' type 16-19 passenger capacity aircraft as compared to the larger 28-30 passenger aircraft previously planned by Applicant.

- Freight cargos will be limited in the same way, with cargo transport capabilities reduced from 45,000 lbs to the <5000 lbs capacity of the 'Twin Otter' sized aircraft.
- Well control equipment and response capabilities of using the Hercules L100-30 aircraft will not be available without the 5600 ft. ice airstrip. An alternate means of supplying the well control equipment would be to pre-stage it at the Central, East and West Well Pads prior to drilling or stage in Deadhorse and rely on tundra vehicles or ice road transport in case of response needs.
- Personnel and cargo movements (e.g. food, consumables, spare equipment and parts, equipment requiring offsite repair) for Operations would be accomplished via these smaller aircraft and transfers from other aircraft in Deadhorse, which builds permanent inefficiencies into the long term operations and decreases facility availability. While a Twin Otter has <5000 lbs total freight capacity, it does not have fork lift loading capability, therefore limiting parcel handling to a two person effort and restricting size severely and weight to less than 200 lbs. The complete impact of this restriction needs further analysis, although a likely conclusion will be that some equipment will not be able to be broken down into small enough parcels to transport for repair offsite (e.g. gas turbine, motors, high pressure valves, etc.).

6.0 ISSUES

This is a very preliminary screening study for purposes of EIS alternative comparison and is based upon the best professional judgment of the people involved and collective knowledge and experience as detailed in the Section 1.0. Due to the limited definition of the alternative and limited time available for evaluation, there are a number of critical issues which were not and could not be fully addressed. This section is intended to identify the more significant issues that would need further evaluation before the alternative could be capable of being implemented in the estimated timeframe. It is worth noting that most of these issues are related to the logistics limitations imposed by the reduce airstrip and lack of infield gravel roads.

6.1 Infrastructure

Water Balance Study:

- Currently permitted water sources may not meet Alternative 4's water needs.
- Water requirements need to be established and sources need to be identified and permitted, particularly with respect to ice roads and pads.

Airstrip:

- The limited airstrip would require a thorough review of aviation plans by ExxonMobil Aviation Department, especially any proposed winter ice-pad extension. This airstrip length prevents the ability to fly in well control equipment and limits operational and facility maintainability capabilities which may cause lengthy delays. Flight operations would be largely limited to Deadhorse-Point Thomson routes.
- Noise and air emissions from increased helicopter operations will be expected.

Multi Year Ice Pads:

- Multi-year ice pads have not been proven to be feasible as a past practice for long term drilling
- Need to study effects on a multi year ice pad with use of a drill rig for two continuous years, including effect of vibrations, interaction with partial gravel pad, and the risks associated with a summer failure.
- There may be environmental issues related to tundra damage from long term (five years) multi year ice pads.
- Multiple design challenges would need to be addressed in order to determine their feasibility, i.e., thickness of ice, thermal transfer at gravel / ice interfaces, etc.

6.2 Wells

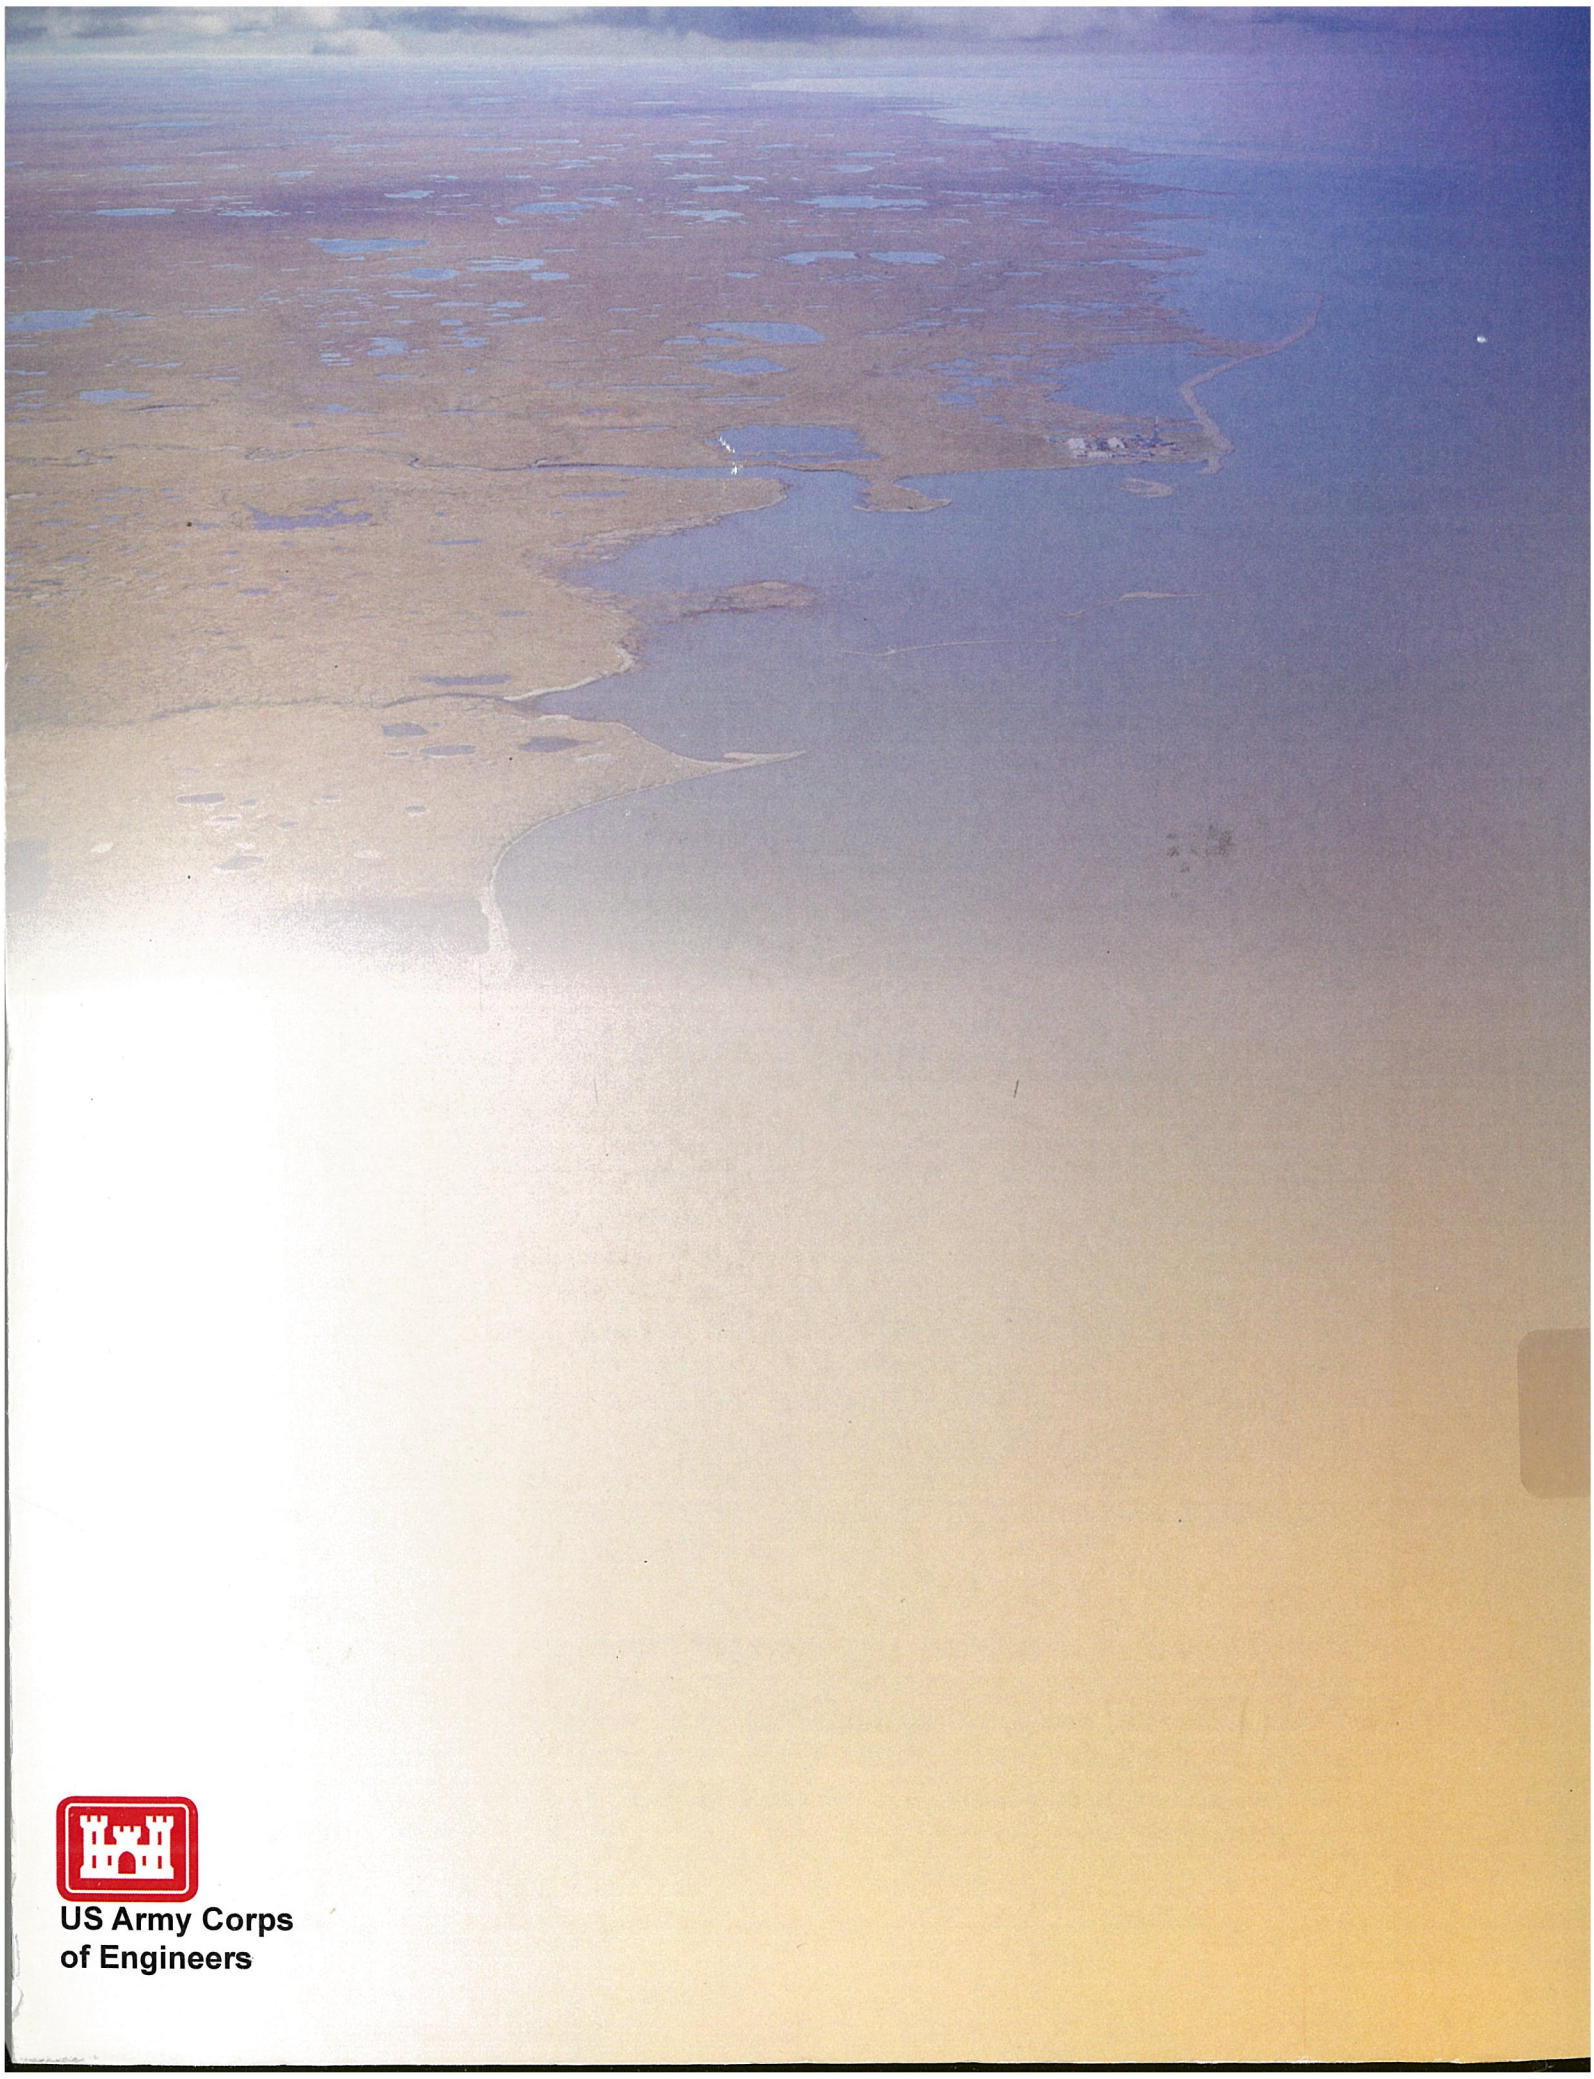
Assuming the viability of multi-year ice pads, the primary issues of Alternative 4 are:

- Extended season due to the restrictions imposed by only having infield tundra ice roads for logistical support
  - With local gravel road support the rig could be moved to any pad any time of the year, and once supplies reached the local area by barge, ice road or air, they could be moved to the drilling pad where they were needed. In Alternative 2, drilling activities are assumed to begin in November of each drilling season, because supplies can be brought in by barge and distributed to the active pad immediately

thus having the drilling rig ready at that time. In Alternative 4, supplies can be barged in, but they cannot be moved to a well pad until tundra ice roads are completed the following winter, delaying the start of drilling to about mid-January. In addition, some time is lost at the end of each season when operations cannot continue into May-June due to the loss of the ice roads. The effect of this is to increase the drilling campaign about two and a half years relative to Alternative 2.

- Increased Central Pad size for stockpiling equipment due to restricted logistical support capability
  - To make drilling operations as efficient as possible, materials would be transported by barge in the summer and stockpiled so they were readily available as soon as tundra ice roads were completed, rather than having to wait for the ice road from Deadhorse to be built. Space to accommodate these supplies would have to be provided on the Central Pad. A specific estimate of this space requirement has not been completed.
- Increased size of East and West Well Pads due to restricted access:
  The inability to fly in well control equipment and restricted access to the East and West Well Pads would require that the well control and spill response equipment kits that are needed in case of an emergency would have to be moved with the rig and stored on the pad. (In Alternative 2, an airstrip capable of supporting Hercules type aircraft addressed this requirement). This space requirement would be approximately 13,500 sq. ft., or an area about 150’ x 90’
  - Space would be needed for a caretaker camp, Connexes, and storage for fuel and water. Furthermore, a safety zone between the fuel storage, well heads and would be needed.
  - The well control and spill response kits include a variety of heavy equipment that may pose additional considerations relating to ice pad integrity.

6.3 Logistics



As noted in elsewhere in Section 6.0, a substantial number of the issues associated with Alternative 4 are related to the logistical limitations imposed by the smaller airstrip and lack

of gravel roads between the Central Pad and the East and West Pads. These items are not repeated here.

6.4 Operations

While the full analysis of operational impacts is beyond the scope and time available for this scenario, it should be noted that Alternative 4 will not allow for '24/7' access which greatly limits the ability to safely and efficiently operate oil and gas wells and maintain the facility. The following are examples of possible knock on effects to long term operations resulting from limited access and additional issues will likely arise as these are studied further.

- Operations will require personnel access to the well pads and this will entail additional helicopter flights, when other modes of transport are not available.
- Emergency response access, relief and evacuation requirements for personnel would need to be considered given the lack of year round access and demonstrated record of no fly days due to weather. Weather related grounding of helicopters can be up to a week or more.
