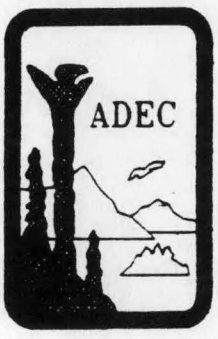
Compilation and Analysis by James C. Gibeaut, Ph.D., Consulting Geologist

January, 1994



SEGMENT: LA 015 E

LOCATION: Chenega Area Group, northeastern shore of Latouche Island

OTHER STUDIES

PHYSICAL SETTING

Coastal Morphology and Sedimentology

Irregular headland, wave-cut platform, and gravel beach shoreline Rounded pebble and large cobble beach in the northern part of the site is protected by prominent seaward outcrops. Subsurface matrix sediment is sandy granules. Large angular boulders occur near outcrops and in the high intertidal of the southern part of the site.

Environmental Sensitivity Index (ESI)

Type 1; rocky coast.
Type 2; exposed wave-cut platform.
Type 7; gravel beach.

Fetches and Directions (kilometers)

NE= 110

Energy Level

High with some moderate locations behind seaward outcrops.

GENERAL BIOLOGICAL SETTING

Oiled mussel bed.
Eagle nest.
Fish harvest area.

OILING SUMMARY

Several large and concentrated areas of AP and SOR persist at this site. All the sites are in areas where large boulders or outcrops provide protection from waves. The worst is location 'G', which is a 29 by 11 m area amongst large boulders. MS was oozing out from beneath the boulders during the survey, and there has been no discernible improvement since 1991.

Subsurface location ZB, which includes pits #6 through 10 and 12 through 19, has a large amount of MOR, HOR, and OP. ZB is located in the pebble and large cobble beach behind a prominent seaward outcrop. Even though this site still retains considerable oil, it has improved greatly since 1991, when it was mechanically tilled, and since 1992, when manual removal occurred. The amount and level of oiled sediment reduced by about 75% from 1991 to 1993.

Locations ZD and ZE had no or little subsurface oil in 1993, but had large amounts in 1991. ZD is down slope of surface area 'G', and ZE extends to the south of location 'H'. Workers manually removed oiled-sediment in 1991 at both sites, but the large amounts indicate that natural removal was also important.

Overall, there has been a large reduction in subsurface oil at this site since 1991.

AFFILIATION
NAME USCG - BOB TEMES SIGNATURE [signature]

MUSSEL BED IN MAIN BEACH HAS SIGNIFICANT AMOUNTS OF MUL/LOR 4"-6" DEEP. UNIT 2 HAS MOR/MOR/OP IN PATCHES IN AND AROUND SOME BOULDERS THERE WAS COAT ON SOME BOULDERS ON THE RIGHT SIDE. I CONCUR W/ THE CONDITIONS INDICATED ON THE MAP & PIT LOG.

AFFILIATION DNR - DIV. OF LAND
NAME KATIE FARLEY SIGNATURE Kathleen M. Farley

The presence of oil in the mussel beds disrupts subsistence use ~~and~~ gathering within the intertidal area for an indefinite time. Eagle nests and commercial fishing are not directly affected by the site's current condition

Loc.= location name of specific oiling area (subsite).
1993 PIT #= the number designations, as indicated on the 1993 survey forms, of the pits in the subsite.
Gr. Sz.= grain size, a dash separates surface from subsurface sediments, B= boulders, C= cobbles, P= pebbles, G= granules, S= sand, M= mud, Pt= peat.
Zn.= inter tidal zone, S= supra tidal, H= high inter tidal, M= mid inter tidal, L= low inter tidal.
En.= wave-energy level, H= high, M= moderate, L= low, VL= very low.
TREATMENT= cleanup treatment occurring at the subsite for the given year, ET= equipment tilling (heavy equipment), MT= manual tilling, BR= berm relocation, SR= sediment relocation, Rb= oiled-sediment removal from subsurface, Rs= oiled-sediment removal from the surface, MB= manual breakup, MR= manual raking, ?= unknown, NO = no treatment.
OILED SED. VOL.= oiled-sediment volume in cubic meters by year and oil type, OP= oil pore, pore spaces are completely filled with oil resulting in oil oozing out of sediments - water cannot penetrate OP zone, HOR= heavy oil residue, pore spaces partially filled with oil residue but not generally flowing out of sediments, MOR= medium oil residue, heavily coated sediments; pore spaces are not filled with oil - pore spaces may be filled with water, LOR= light oil residue, sediments lightly coated with oil, OF= oil film, continuous layer of sheen or film on sediments - water may bead on sediments, TR= trace, discontinuous film; spots of oil on sediments; an odor or tackiness with no visible evidence of oil, ?= area of subsite not visited or adequately surveyed.
WT.'ed OIL VOL.= weighted oiled-sediment volume = (OP VOL)*5 + (HOR VOL.)*4 + (MOR VOL.)*3 + (LOR VOL.)*2
% CHANGE WT.'ed VOL.= % change in weighted oiled-sediment volume between the given years = ((year 2 - year1)/(year 1))*100, positive values indicate increases in the amount of oil, negative values indicate decreases, "Inf" (infinite percent increase) indicates newly discovered oil.

SEGMENT: LA 019 A

LOCATION: Chenega Area Group, Sleepy Bay, north shore of Latouche Island

OTHER STUDIES

Tesoro 1993 PES-51 test site.

ADEC transect station # 43 (actually in LA 018 A)

PHYSICAL SETTING

Coastal Morphology and Sedimentology

Boulder beach with complicated sediment and bedrock distribution. Sediments are subangular boulders and subrounded cobbles overlying pebbles and boulders and cobbles with a sandy, granular matrix. Low bedrock outcrops are important along the beach, and a large outcrop and large boulder area oriented normal to shore separates about 1/4/ of the eastern end of the site from the rest of the beach. A storm berm is present.

Environmental Sensitivity Index (ESI)

Type 1; exposed rocky.

Type 7; gravel beach.

Fetches and Directions (kilometers)

N= 14; NE= 110

Energy Level

High with some moderate areas.

GENERAL BIOLOGICAL SETTING

OILING SUMMARY

The eastern 1/4 of the site, which is to the east of a prominent outcrop and large boulder area that separates this area form the rest of the beach, has a large and concentrated area of AP and MS amongst boulders and cobbles. The concentration in this area, which is designated as location 'G', is between 11 and 50% and occurs in the mid and upper intertidal zones. No detectable improvement has occurred here since 1991, and only manual pickup of AP was performed in 1991 with no treatment occurring in 1992.

Several other areas have relatively concentrated amounts of surface oil amongst boulders but cover smaller areas at the west end of the site and the east end, west of the eastern dividing bedrock. The area covered by locations 'C', 'E', and 'F' in 1993 greatly improved since 1991. The storm berm area also greatly improved. Sites in very large boulders near bedrock on the western end (location 'A') and the eastern end (west side of dividing bedrock and large boulders, location 'H') did not noticeably improve.

Most of the oil at this site has been recorded as surface oil and thus has been minor relative to reported surface oil amounts. Because of the complicated distribution of sediments both across the beach and with depth, it is difficult to map the subsurface oil. The recorded subsurface oil amounts and levels of concentration (OP, HOR etc.),however, were about the same in 1991 and 1993. The greatest amount occurred in the upper and mid-intertidal zone across the central part of the boulder beach in 1993 (location ZA, pits 1-3, 5,7,8, and 10-14).

SHORELINE SURVEY COMMENT SHEET

LOCATION ATOUCHE SEGMENT LA019 SUBDIVISION A DATE 07 / 17 / 93

AFFILIATION
NAME [illegible] Moors / USCG SIGNATURE [illegible]

PES-51 treated area appeared [illegible] cut [illegible] down [illegible] and PES [illegible] PES treated [illegible] did [illegible] [illegible].

AFFILIATION DNR, Div. of Land
NAME Katie Farley SIGNATURE Kathleen M. Farley

If the PES-51 treatment is determined to be conducive for restoration and the application methodology is improved, this would probably be a worthwhile site for further treatment because it was one of the most heaviest hit areas and there are still a lot of patches of [illegible], its proximity to the Village of Cherega, and because of its "notoriety" among the public.

Loc.= location name of specific oiling area (subsite).
1993 PIT #= the number designations, as indicated on the 1993 survey forms, of the pits in the subsite.
Gr. Sz.= grain size, a dash separates surface from subsurface sediments, B= boulders, C= cobbles, P= pebbles, G= granules, S= sand, M= mud, Pt= peat
Zn.= inter tidal zone, S= supra tidal, H= high inter tidal, M= mid inter tidal, L= low inter tidal.
En.= wave-energy level, H= high, M= moderate, L= low, VL= very low.
TREATMENT= cleanup treatment occurring at the subsite for the given year, ET= equipment tilling (heavy equipment), MT= manual tilling, BR= berm relocation, SR= sediment relocation, Rb= oiled-sediment removal from subsurface, Rs= oiled-sediment removal from the surface, MB= manual breakup, MR= manual raking, ?= unknown, NO= no treatment.
OILED SED. VOL.= oiled-sediment volume in cubic meters by year and oil type, OP= oil pore, pore spaces are completely filled with oil resulting in oil oozing out of sediments - water cannot penetrate OP zone, HOR= heavy oil residue, pore spaces partially filled with oil residue but not generally flowing out of sediments, MOR = medium oil residue, heavily coated sediments; pore spaces are not filled with oil - pore spaces may be filled with water, LOR= light oil residue, sediments lightly coated with oil, OF= oil film, continuous layer of sheen or film on sediments - water may bead on sediments, TR= trace, discontinuous film, spots of oil on sediments; an odor or tackiness with no visible evidence of oil, ?= area of subsite not visited or adequately surveyed.
WT.'ed OIL VOL.= weighted oiled-sediment volume = (OP VOL.)*5 + (HOR VOL.)*4 + (MOR VOL.)*3 + (LOR VOL.)*2
% CHANGE WT.'ed VOL.= % change in weighted oiled-sediment volume between the given years = ((year 2 - year1)/(year 1))*100, positive values indicate increases in the amount of oil, negative values indicate decreases, "Inf" (infinite percent increase) indicates newly discovered oil

SEGMENT: LA 020 C

LOCATION: Chenega Island Area Group, north end of Latouche Island, west shoreline of Sleepy Bay.

OTHER STUDIES

PHYSICAL SETTING

Coastal Morphology and Sedimentology

Linear boulder and cobble beach about 900 m long. The beach is gently sloping with bedrock near the surface and exposed in places. The entire beach contains boulders but in some areas very large boulders are present. A cobble and drift log storm berm is present along the shoreline. Sediments are subangular to subrounded and at depth a granular matrix occurs. In some areas a clayey sediment is present at depth (pits #17-22). A low rocky promontory projects from the beach at one location behind which bedrock outcrop occurs.

Environmental Sensitivity Index (ESI)

Type 2; exposed wave-cut rock platform.
Type 7; gravel beach.

Fetches and Directions (kilometers)

N= 14; NE= 110

Energy Level

High with some moderate areas.

GENERAL BIOLOGICAL SETTING

Eagle nest.
Deer harvesting.

OILING SUMMARY

Four large areas of significant surface oiling occur at this site. Location 'C' contains a relatively high concentration of AP behind the promontory described above. At the north end of the site, location 'D' also contains a high concentration of AP and SOR. Locations 'C' and 'D' are both in the upper intertidal zone.

Locations 'A' and 'B' are two very large areas with moderate concentrations of AP and SOR in the mid and upper intertidal zones.

Based strictly on office interpretations of the data collected by the oiling geomorphologists in 1991 and 1993, it appears that significant improvement has occurred at locations 'A' and 'C', and 'D'. These areas had coverage of more than 11% in 1991, but generally less than 11% in 1993. The storm berm also appears to have improved since 1991 all along this beach. The area between location 'C' to the south and location 'D' to the north also appears to have significantly improved since 1991. Much manual removal occurred at these locations in 1991 and 1992.

Three significant areas of LOR to OP oil remains at this site The largest location is ZB, which is coincident with surface location 'B'. Location ZA is amongst the very large boulders of surface location 'A'. Both these locations are in the mid-intertidal zone and ZA extends to the lower intertidal zone while ZB extends to the upper intertidal zone

Location ZC is a continuous lens of HOR and OP in pebble, cobble gravel at the base of the storm berm of surface location 'B'.

The 1991 and 1992 surveys did not provide adequate information for comparisons through time of subsurface oil.

21 x 1 meter band of AP + SOR AP occasionally under beneath
130m x 1-3m band - P of hard AP, Tarmat, TAR and boulders, large cobbles and tilted sedimentary bedrock behind promontory, just below storm berm
C
LONG LOW ROCKY PROMONTORY
B
Storm berm w/drift logs, boulder, cobble field. 20 x 200 meter area of AP SOR from MIT2 thru HIT2 interstitially among boulders and cobbles. Oiling is heavier than in area A and occurs in distinct patches. The surface AP SOR often extend subsurface. At the base of the storm berm a continuous distinct lens of HOR/OP was defined as 2-5 meters x 44 meters x 20cm thick. This lens is easily uncovered from cobbles & boulders.
A
1m x 100m Area of AP SOR from LIT2 thru HIT2 occuring interstitially in and around boulders and cobbles. Not necessarily in distinct patches. Oil is interstitially in crevices and is difficult to access. This area contains very large boulders and cobbles.

Loc.= location name of specific oiling area (subsite).
1993 PIT #= the number designations, as indicated on the 1993 survey forms, of the pits in the subsite.
Gr. Sz.= grain size, a dash separates surface from subsurface sediments, B= boulders, C= cobbles, P= pebbles, G= granules, S= sand, M= mud, Pt= peat.
Zn.= inter tidal zone, S= supra tidal, H= high inter tidal, M= mid inter tidal, L= low inter tidal.
En.= wave-energy level, H= high, M= moderate, L= low, VL= very low.
TREATMENT= cleanup treatment occurring at the subsite for the given year, ET= equipment tilling (heavy equipment), MT= manual tilling, BR= berm relocation, SR= sediment relocation, Rb= oiled-sediment removal from subsurface, Rs= oiled-sediment removal from the surface, MB= manual breakup, MR= manual raking, ?= unknown NO no treatment.
OILED SED. VOL.= oiled-sediment volume in cubic meters by year and oil type, OP= oil pore, pore spaces are completely filled with oil resulting in oil oozing out of sediments - water cannot penetrate OP zone, HOR= heavy oil residue, pore spaces partially filled with oil residue but not generally flowing out of sediments, MOR= medium oil residue, heavily coated sediments; pore spaces are not filled with oil - pore spaces may be filled with water, LOR= light oil residue, sediments lightly coated with oil, OF= oil film, continuous layer of sheen or film on sediments - water may bead on sediments, TR= trace, discontinuous film, spots of oil on sediments; an odor or tackiness with no visible evidence of oil, ?= area of subsite not visited or adequately surveyed.
WT.'ed OIL VOL.= weighted oiled-sediment volume = (OP VOL.)*5 + (HOR VOL.)*4 + (MOR VOL.)*3 + (LOR VOL.)*2
% CHANGE WT.'ed VOL.= % change in weighted oiled-sediment volume between the given years = ((year 2 - year1)/(year 1))*100 positive values indicate increases in the amount of oil, negative values indicate decreases, "Inf" (infinite percent increase) indicates newly discovered oil.

LOCATION: Chenega Island Area Group, northwestern shore of Latouche Island

OTHER STUDIES

PHYSICAL SETTING

Coastal Morphology and Sedimentology

This is a 200 m long gently sloping boulder cobble beach overlying a shallow bedrock platform. A few prominent outcrops occur. Sediments are subangular to subrounded boulders and large cobbles on the surface with pebbles in the interstices and a granular matrix in the subsurface. A gravel and drift log storm berm is present.

Environmental Sensitivity Index (ESI)

Type 2; exposed wave-cut rock platform.
Type 7; gravel beach.

Fetches and Directions (kilometers)

N= 16; NW= 23; W= 4

Energy Level

Moderate.

GENERAL BIOLOGICAL SETTING

Eagle nest.
Deer harvesting.

OILING SUMMARY

Location 'B' is a large area 5 by 200 m long extending along the entire site and occurring in the mid to upper intertidal zones. AP and SOR occur at a coverage of about 10%. Location 'A' is a smaller area (50 by 10 m) on the southwest end of the site with only about a 1% coverage of AP and SOR. No measurable improvement has occurred at these sites, but it is emphasized that the survey methods can only detect rather large changes and reductions have probably occurred. Manual removal occurred in site 'B' in 1991 and manual breakup in 1992.

Twenty pits defined a subsurface oil area that is coincident with surface location 'B' and contains minor amounts of LOR to HOR oil. The subsurface oil is discontinuous and often resides on bedrock. It is estimated that only about 5% of the area covered by pits 1-20 (subsurface location ZA) contains subsurface oil. This site has improved since 1991 when OP oil was present. In 1991, workers manually removed oiled subsurface sediment.

LOCATION: Chenega Area Group, northeastern shore of Latouche Island

OTHER STUDIES

PHYSICAL SETTING

Coastal Morphology and Sedimentology

Very large boulders as a veneer on an irregular wave-cut platform with a small storm berm. Stream enters just to the north and supplies pebble and cobble sediments.

Environmental Sensitivity Index (ESI)

Type 2; exposed wave-cut rock platform.

Fetches and Directions (kilometers)

NE= 46; E= 11; SE= 11; S= 17

Energy Level

High.

GENERAL BIOLOGICAL SETTING

Anadromous stream.
Eagle nest.
Deer harvesting.
Finfish harvesting.

OILING SUMMARY

Surveyors in 1993 recorded two small upper intertidal locations of four square meters each on the southern most portion of LA 031 A. The SOR, MS, CV, and CT occur among very large boulders on a wave-cut platform. Percent coverage within these areas is on the order of 5%. There appears to have been little change since 1992, and the area was apparently not surveyed in 1991. In 1992 the southern most location, location 'A' was recorded as 10 square meters with the same coverage, therefore, this may indicate a slight improvement. Accessible MS was removed at these locations in 1992. It should be noted that in 1992, surveyors reported numerous "non-EVOS" tar balls in the lower intertidal zone at this site.

Surveyors recorded no subsurface oil in 1993, and in 1992, only a small amount was recorded in the area coincident with surface location 'B' (subsurface location ZA). Thus a small improvement may have occurred.

Energy Level

High with some moderate bedrock-protected areas.

GENERAL BIOLOGICAL SETTING

Eagle nest.

OILING SUMMARY

Only one small area of AP and one of MS was present in 1993. In 1992, workers relocated MS in location 'A4'. In 1992, the MS covered an area 5 by 6 m in size and was 2 to 11 cm thick. In 1993, there was only a trace of MS in an area 0.5 by 0.5 m. The AP in location 'A1' was reported in 1992 as about three times the size as it was in 1993. Thus significant improvement has occurred at this site since 1992, largely due to treatment. Significant improvement also occurred at location 'A5' since 1991 when surveyors reported a 2 by 8 m area with 20% coverage of MS. In 1993, this area had less than 11% coverage of tarballs. It should be noted that in 1991, the oiling geomorphologist indicated that "non-ANS" (sp?) tar occurred along this site. It is not know what is meant by his note, but he may have been indicating that tar other than that from the Exxon Valdez was present.

The only subsurface oil recorded in 1993 was a small pocket of HOR. A 200 m^2 area of OF/Tr to MOR was discovered in 1991 in the area coincident with the 1993 surface location 'A2'. This oil was not present in 1993. In 1992, subsurface oil associated with the surface MS in surface location 'A4' was not present in 1993. Therefore, significant improvement in the amounts of subsurface oil occurred.

Large concentrations of tarballs.

I agree with the survey results.

Note * Large pads of Wally Noerenberg Fish Hatchery's missing fish pens are on the beach by the pond. 30' x 2' ABS pipe needs to be removed by PWSAC

AFFILIATION ADEC

NAME Joanne Hanson SIGNATURE Joanne Hanson

The most significant observation was the improvement in oiling condition from 1992. The State survey crew excavated and exposed oil in 1992 and believe that this treatment greatly enhanced the recovery of this subdivision. Oil remains but in small isolated amounts.

AFFILIATION U.S. Forest Service

NAME Liz Baer SIGNATURE Liz Baer

Only a minimal amount of surface asphalt and tar and not obvious to recreationists. Recommend no additional treatment needed.

OILING SUMMARY

Two small areas of MS and SOR remain in 1993. These areas occur in the upper to supra intertidal zone amongst boulders in the northern part of the segment. Both areas are in a narrow protected cove and were relocated by the 1993 survey team. In 1993 these areas were only 1.5 and 4 m^2 in size, but in 1992 they had a total area of 36 m^2, and a much higher concentration. Workers relocated these sediments in 1992, which resulted in the significant improvement in this area. No detectable improvement occurred from 1991 to 1992. The state vessel performed manual removal (15 geobags) at this segment in 1991, but it is not clear exactly where the sediment was removed.

A small amount of OP and HOR oil was discovered at one location in 1993. The location includes and extends beyond surface location 'B' by a few 10's of meters. Four pits of OP and HOR oil were recorded in 1992, but the pit locations were not indicated on the map. Essentially no subsurface oil was reported in 1991.

Energy Level

High with moderate areas.

GENERAL BIOLOGICAL SETTING

Oiled mussel bed.
Eagle nest.
Fry release.
Fish harvest area.

OILING SUMMARY

Only trace amounts of CT was surveyed in one location in 1993. This location, location 'D', contained a greater than 50% cover in a 2 by 5 m area of AP. Several other areas on site #1 contained high concentrations of AP and SOR in 1991 but had no surface oil in 1993. Thus improvement occurred.

Oil in a mussel bed and tide pool on site #1 and in the vicinity of pit #8 was recorded as surface oil in 1991. In 1993, this same area was recorded has having substantial amounts of LOR, MOR, and HOR oil in the mussel bed and above a peat layer. Sheening was observed without disturbance of the sediment. Apparently this location (location ZC) has not improved since 1991 even though it was manually treated in 1991 and 1992.

Another subsurface oil area is location ZA also on site #1. This location occurs in the lower and mid-intertidal zones and was sheening in 1993 (see photo 93MSP003-11). No subsurface oil was recorded here in 1991, but "surface" oil was removed in 1991 and 1992.

OTHER STUDIES

NOAA transect station =N-17.

PHYSICAL SETTING

Coastal Morphology and Sedimentology

Pebble and cobble pocket beach. Sediments are well rounded. Grain size grades from pebbles to boulders in the lower intertidal. Multiple high-tide berms are commonly present as well as a storm berm. A small gravel tombolo is present in the center of the pocket, and grain size abruptly increases toward each limb. A freshwater lake lies behind the beach causing abundant outflow of freshwater through the beachface at least in the southern half of the pocket.

Environmental Sensitivity Index (ESI)

Type 7, gravel beach.

Fetches and Directions (kilometers)

E= 24; SE= 24

Energy Level

High.

GENERAL BIOLOGICAL SETTING

Eagle nest.
Fish harvest area.

OILING SUMMARY

One area of AP and SOR remains in the boulder field at the base of the bedrock on the north limb. It was estimated that less than 11% coverage occurs at this location, but in 1991 more than 11% was present. Manual pickup occurred at this location in 1991.

Two areas of significant subsurface oil remain at this site. Both areas (ZA and ZB) are in the southern half of the site. Location ZA is in the upper and mid intertidal zones amongst boulders along the south limb. MOR and HOR oil occurs here, and there has been no improvement since 1991. Location ZB is in the mid intertidal zone just south of the tombolo. MOR and LOR occurs below clean surface boulders and cobbles in this exposed portion of the site. Much improvement occurred here with less than half of the oil remaining in 1993 than was present in 1991.

Several other small areas of subsurface oil completely cleaned up since 1991, despite only minor treatment in 1991 and no treatment in 1992. Overall, the amount of subsurface oil has decreased by 50% since 1991. The berm was relocated in 1990.

SUBSURFACE OIL PRESENT IN BOULDER AREAS AND MITZ. STORM BERM RELOCATION IN 1990 WAS EFFECTIVE BUT OIL DESCRIBED ABOVE HAS BEEN PERSISTENT. NO SHEEN IN FROM UNDISTURBED AREAS NOTED.

AFFILIATION U.S. Forest Service
NAME Ric Baer SIGNATURE [signature]

Small amounts of tar and needles observed on surfaces of bedrock. Subsurface oil in rocky area on south end of beach that could be treated with PES51, but is not necessary (area A) During clean-up of beach the old beach logs were windrowed above the high tide line and are still there in that unnatural state. These logs should have been relocated after the clean-up was completed with heavy equipment. It is now going to be very difficult if not impossible to improve appearance.

AFFILIATION DNR
NAME Wyn Menefee SIGNATURE Wyn Menefee

Recording of oil on DEC sheet is correct. Human use is prevalent. Gillnet + set net site. Two hiking trails (well used) eminate from beach to otherside of Mears Point. Sub surface oil persisting. The beach logs were all pushed up to the top berm above extreme tides. Looks unnatural [redacted] forms potential camping area. Mariculture [redacted] in same bay. Note additional report on S. Perry [redacted] site. Oil not sheening until disturbed.

AP= asphalt; MS= mousse; SOR= surface oil residue; CV= cover; OT= boat
Areas are computed by multiplying the affected area by the percent coverage of each oil type. Field categories of percent oil coverage are converted to the median percent value as follows:
continuous= 95%; broken= 70%; patchy= 30%; sporadic= 6%; trace= 1.5%

Loc.= location name of specific oiling area (subsite).
1993 PIT #= the number designations, as indicated on the 1993 survey forms, of the pits in the subsite.
Gr. Sz.= grain size, a dash separates surface from subsurface sediments, B= boulders, C= cobbles, P= pebbles, G= granules, S= sand, M= mud, Pt= peat.
Zn.= inter tidal zone, S= supra tidal, H= high inter tidal, M= mid inter tidal, L= low inter tidal.
En.= wave-energy level, H= high, M= moderate, L= low, VL= very low.
TREATMENT= cleanup treatment occurring at the subsite for the given year, ET= equipment tilling (heavy equipment), MT= manual tilling, BR= berm relocation, SR= sediment relocation, Rb= oiled-sediment removal from subsurface, Rs= oiled-sediment removal from the surface, MB= manual breakup, MR= manual raking, ?= unknown, NO= no treatment.
OILED SED. VOL.= oiled-sediment volume in cubic meters by year and oil type, OP= oil pore, pore spaces are completely filled with oil resulting in oil oozing out of sediments - water cannot penetrate OP zone, HOR= heavy oil residue, pore spaces partially filled with oil residue but not generally flowing out of sediments, MOR= medium oil residue, heavily coated sediments; pore spaces are not filled with oil - pore spaces may be filled with water, LOR= light oil residue, sediments lightly coated with oil, OF= oil film, continuous layer of sheen or film on sediments - water may bead on sediments, TR= trace, discontinuous film, spots of oil on sediments, an odor or tackiness with no visible evidence of oil, ?= area of subsite not visited or adequately surveyed.
WT.'ed OIL VOL.= weighted oiled-sediment volume = (OP VOL.)*5 + (HOR VOL.)*4 + (MOR VOL.)*3 + (LOR VOL.)*2
% CHANGE WT.'ed VOL.= % change in weighted oiled-sediment volume between the given years = ((year 2 - year1)/(year 1))*100, positive values indicate increases in the amount of oil, negative values indicate decreases, "Inf" (infinite percent increase) indicates newly discovered oil

OTHER STUDIES

PHYSICAL SETTING

Coastal Morphology and Sedimentology

Gently sloping pocket beach formed by a stream delta. Sediments are subangular pebbles and cobbles on the surface with a sand and mud matrix in the subsurface. Angular boulders occur in the upper intertidal and sediments decrease in size down the beach. Drift logs and a storm berm are present on the western portion of the beach. The stream has several distributary channels that cross the delta.

Environmental Sensitivity Index (ESI)

Type 7; gravel beach.
Type 8; sheltered rocky.

Fetches and Directions (kilometers)

N= 1; NE= 12

Energy Level

Low to moderate.

GENERAL BIOLOGICAL SETTING

Oiled mussel and fucus beds.
Eel grass and subtidal clam bed (clam bed not well developed).
Eagle nest.
Herring spawning.
Fish harvest area.

OILING SUMMARY

A 20 by 60 m area with a 1 to 11% coverage of SOR remains in the mid and lower intertidal zones. Active sheening was observed throughout this location (location 'A') which includes fucus and mussel beds in front of the stream entrance. This area has improved somewhat since 1991, although it is very difficult to estimate percent coverage of the oil.

Silver sheens were observed in location 'D'; this area, however, undoubtedly significantly improved since 1991. Location 'D' is in the mid to upper intertidal and contained more than 10% SOR in a 20 by 70 m area in 1991. In 1993, only trace amounts were observed in an area 10 by 20 m.

Manual raking, tilling, and removal occurred at locations 'A' and 'D' in 1991, and in location 'A' in 1992.

Small amounts of subsurface oil remain. Location ZB is a HOR and OP layer 1 by 7 m in size. Location 'C' was defined as surface oil but one could also interpret the oil as

subsurface. Photo 93CSC009-31 shows the surface and shallow subsurface layer exposed along a cut stream bank in location 'C'.

Location ZA retains a small amount of LOR below mussels and fucus in an area of 30 square meters, but this is a great improvement over 1991 conditions when MOR oil covered a 1200 square meter area.

The above mentioned subsurface areas were treated in 1991 with manual raking, tilling, and removal, and in addition, workers removed oil on the surface in location ZA in 1992

Overall, conditions have greatly improved since 1991, but persistent sheening is evidence of continuing pollution.

AFFILIATION DNR Div of Parks

NAME Roger L. MacCampbell SIGNATURE [signature]

Surveyed L-MITZ, sheens observed on surface throughout area due to light rain, particularly near streams. Pink salmon observed in streams (4-5)

Subsurface oil found 10-13 cm deep in areas B + C mousse w/ heavy sheen when mixed w/ water. Area A + (Map) found surface oil + sheens spotty throughout area.

Does not appear to be as much fucus as in 89-90

Evidence of work from previous years still visible.

SHEEN COLOR: B = BROWN; R = RAINBOW; S = SILVER; N = NONE

OG COMMENTS: Survey limited to Low-Mid Intertidal zone.

Light RAIN induced Silty Sheens throughout the intertidal in locations A, B & D, E. Sheens/FL Associated with Surface oil residual - L-H.

Evidence of previous work (ie. impressions from Landing Craft & excavation pits) remain.

In locations B & C - subsurface oiling persists below Cobble armor - up to 13cm deep.

1993 Surface Oil Summary
Segment TB004 Subdivision A

Location	Area of Oiling Type in Square Meters AP	MS	SOR	CV	CT
A	0.	0.	72.	0.	0.
B	0.	0.	0.035	0.	0.
C	0.	0.	0.36	0.	0.
D	0.	0.	1.	0.	0.
E	0.	0.	0.03	0.	0.
TOTALS=	0.	0.	73.425	0.	0.

AP= asphalt; MS= mousse; SOR= surface oil residue; CV= cover; CT= coat
Areas are computed by multiplying the affected area by the percent coverage of each oil type. Field categories of percent oil coverage are converted to the median percent value as follows:
continuous= 95%; broken= 70%; patchy= 30%; sporadic= 6%; trace= 0.5%

Loc.= location name of specific oiling area (subsite).
1993 PIT #= the number designations, as indicated on the 1993 survey forms, of the pits in the subsite.
Gr. Sz.= grain size, a dash separates surface from subsurface sediments, B= boulders, C= cobbles, P= pebbles, G= granules, S= sand, M= mud, Pt= peat.
Zn.= inter tidal zone, S= supra tidal, H= high inter tidal, M= mid inter tidal, L= low inter tidal.
En.= wave-energy level, H= high, M= moderate, L= low, VL= very low.
TREATMENT= cleanup treatment occurring at the subsite for the given year, ET= equipment tilling (heavy equipment), MT= manual tilling, BR= berm relocation, SR= sediment relocation, Rb= oiled-sediment removal from subsurface, Rs= oiled-sediment removal from the surface, MB= manual breakup, MR= manual raking, ?= unknown, NO= no treatment.
OILED SED. VOL.= oiled-sediment volume in cubic meters by year and oil type, OP= oil pore, pore spaces are completely filled with oil resulting in oil oozing out of sediments - water cannot penetrate OP zone, HOR= heavy oil residue, pore spaces partially filled with oil residue but not generally flowing out of sediments, MOR= medium oil residue, heavily coated sediments; pore spaces are not filled with oil - pore spaces may be filled with water, LOR= light oil residue, sediments lightly coated with oil, OF= oil film, continuous layer of sheen or film on sediments - water may bead on sediments, TR= trace, discontinuous film; spots of oil on sediments; an odor or tackiness with no visible evidence of oil, ?= area of subsite not visited or adequately surveyed.
WT.'ed OIL VOL.= weighted oiled-sediment volume = (OP VOL.)*5 + (HOR VOL.)*4 + (MOR VOL.)*3 + (LOR VOL.)*2
% CHANGE WT.'ed VOL.= % change in weighted oiled-sediment volume between the given years = ((year 2 - year1)/(year 1))*100, positive values indicate increases in the amount of oil, negative values indicate decreases. "Inf" (infinite percent increase) indicates newly discovered oil.
