WEEKLY STREAM FLOWS AND FLOW DURATION CURVES FOR THE SUSITNA RIVER BASIN THREE STAGE PROJECT VOLUME 2 - STAGE III

Weekly streamflow sequences and flow duration curves were derived for natural and with-project conditions for the Susitna River at Watana Damsite, Devil Canyon Damsite, Gold Creek, Sunshine and Susitna Station (see Exhibit 1 for locations) for Case E-VI environmental flow requirements, and energy demands for Stages I, II, and III.

The period of simulation for reservoir operations was based on the historical record at the U.S. Geological Survey gaging station on the Susitna River at Gold Creek (USGS). Thirty-four years of record from December 31, 1949 through December 30, 1983 were simulated. Thirty-three complete water years[1/] are contained in the period of simulation. The results presented in this report are for the 33 water years. The method by which recorded streamflows at the Gold Creek gage and at other gages on the Susitna River were used to develop streamflow sequences at the damsites and to fill the 34-year period where records were missing or where the gaging period was short, is explained in a previous report (HE 1985a). Observed and computed streamflows for major tributaries of the Susitna River including the Chulitna River, Talkeetna River and Skwentna River are contained in another previous report (HE 1984). Flows in these rivers would not be affected by the project.

1/ The standard statistical year is the period beginning October 1 of a year and ending September 30 of the next year. The water year is denoted by the calendar year in which it ends. Each water year is further divided into 52 periods. The first 51 of these periods are of equal 7-day lengths and the last is an 8-day period from September 23 through September 30 (Chow 1964, Linsley, et.al. 1958).

Simulated with-project streamflows are presented for all three stages of the project. Stages I and II are relatively short and previous flow simulations (HE 1985b) show that flows in any one year of either stage would represent conditions during the entire stage. Stage III is much longer than Stages I and II, since it represents the ultimate development of the project. Therefore, flows are provided for early and late Stage III to bound the expected energy production in this Stage. The following table defines the expected energy production in each stage and the energy production for the simulations.

Stage	Period of Operation		Estimated Energy Production		Simulated Energy Production (Gwh/yr)
	Begin	End	Begin (Gwh/yr)	End (Gwh/yr)	
I	1999	2004	2400	2400	2400
II	2005	2011	4200	4750	4400
III	2012	--	5130[1/]	6900	5500[1/] and 6900

1/ The estimated energy production in the first year of Stage III operation is 5130 Gwh. During the period 2011 to 2015 the Stage III reservoir will be filling and the normal maximum water level (el. 2,185) will not be attained until approximately 2015. Thus, the year 2015 would be the first year in which Stage III would operate "normally", that is, with a full reservoir in September. Energy production in this year would be approximately 5500 Gwh and so this was used for flow simulations for early Stage III. During the Stage III filling period, summer flows at Gold Creek would be close to the minimum E-VI requirements since normal excess flows would be used to raise the Stage III normal maximum water level from el. 2,000 to el. 2,185. During winter, flows will gradually change, over the filling period, from those simulated for Stage II to those simulated for early Stage III. Further discussions of flows during filling of Stages I, II and III are contained in the License Application Amendment (APA 1985).

Weekly streamflow sequences are provided in Tables 1-5, 10-12, 17-19, 25-27, and 28-30 for natural conditions, Stage I, Stage II, early Stage III and late Stage III, respectively. These tables show the release from the reservoir(s) divided into three components:

- the discharge through the powerhouse (turbines) to generate energy,
- the discharge through the outlet works (cone valves) to meet the Case E-VI minimum flow requirements, and
- the discharge through the outlet works (cone valves) for flood control purposes; so called excess release. This portion of the outlet works release is made when the water level in the reservoir(s) reaches the normal maximum water level (el. 1,455 at Devil Canyon, el. 2,000 in Watana Stage I and el. 2,185 in Watana Stage III) and inflow to the reservoir(s) exceeds the minimum flow requirements and powerhouse generating capacity.

Each dam also contains a gated overflow spillway which is planned to operate when the reservoir water level exceeds the environmental flood surcharge level. This is at el. 1,456 in Devil Canyon Reservoir, el. 2,014 in Watana Stage 1 and el. 2,193 in Watana Stage III. All floods with return periods of 50 years or less can be stored in these pools and released through the outlet works without using the spillway. For the entire 34-year period of simulation, for each stage of operation, the spillway was not required to be used. For this reason the tables in this report do not contain a column for spillway flows.

In addition to the information on project outflows, the tables contain the estimated intervening flows between the reservoir(s) and the downstream

sites. These flows are added to the reservoir releases to provide the estimated weekly flow sequences at Gold Creek, Sunshine and Susitna Station. Thus, this report provides effects of the proposed Susitna Hydroelectric Project on flows in the Susitna River for the entire 182 mile reach between Watana Dam and Cook Inlet.

The natural and with-project streamflow sequences at each of the two dam sites and the three gaging stations were used to develop weekly flow duration curves. These curves represent the cumulative frequency that a given weekly average flow is equaled or exceeded, based on the 33 water years used in the analysis. (Chow 1964, Linsley, et. al. 1958). The flow duration curves are given in tabular form and are plotted on exhibits. The following table gives the table number for the duration curves for each site and stage.

	Watana	Devil Canyon	Gold Creek	Sunshine	Susitna Station
Natural	6	7	8	9	10
Stage I	14	-	15	16	17
Stage II	21	22	23	24	25
Early Stage III	32	33	34	35	36
Late Stage III	37	38	39	40	41

The following table gives the exhibit numbers for the same information in plot form.

	Watana	Devil Canyon	Gold Creek	Sunshine	Susitna Station
Stage I	2	-	3	4	5
Stage II	6	7	8	9	10
Early Stage III	11	12	13	14	15
Late Stage III	16	17	18	19	20

Natural flow duration curves for each site are plotted on the with-project exhibits.

The flow duration curves indicate a decrease in the difference between the natural and with-project flows as the distance increases downstream from Gold Creek. This is due to the added flow from tributaries joining the Susitna River. The flows from the Chulitna River, Talkeetna River and Yentna River have the most significant effects.

An analysis of the project's effects on the frequency of floods at Watana, Devil Canyon, Gold Creek, Sunshine and Susitna Station has also been performed. This analysis is contained in a separate report (HE 1985c). Information on reservoir water levels and average turbine discharges contained in the tables in this document were used in that analysis.
